NONINVASIVE HEMODYNAMIC STUDY OF THE PULMONARY CIRCULATION (Abstract): Cardiac catheterization is the reference method for the hemodynamic study of the pulmonary circulation. However, cardiac catheterization is an expensive and invasive method. Echocardiography is a reliable noninvasive alternative method. The purpose of our study was to determine the correlation between echocardiographic and haemodynamic data obtained by cardiac catheterization in patients with pulmonary hypertension. **Material and methods:** We conducted a prospective study on 55 subjects diagnosed with pulmonary hypertension. They were examined by echocardiography and cardiac catheterization. The following parameters were measured: systolic, mean and diastolic pulmonary artery pressure and pulmonary vascular resistance. We determined the coefficient of linear correlation (Pearson) between the two methods. **Results:** The mean pulmonary artery pressure obtained by cardiac catheterization was 48.82 ± 18.4 mm Hg; the systolic pulmonary artery pressure at cardiac catheterization was 67.86 ± 22.31 mm Hg; the diastolic pulmonary artery pressure was 32.85± 15.49 mm Hg; the pulmonary resistance was 10.4 ± 5.14 Wood units. We obtained very good correlation between the two methods for systolic pulmonary artery pressure (r 0.847, p <0.0001), mean pulmonary artery pressure (r 0.7, p <0.001), diastolic pulmonary artery pressure (r 0.54, p 0.01) and pulmonary vascular resistance (r 0.82, p <0.001). **Conclusions:** Echocardiography is an excellent method for the hemodynamic study of the pulmonary circulation. **Key words:** PULMONARY HYPERTENSION, ECHOCARDIOGRAPHY, CARDIAC CATHETERIZATION, HEMODYNAMICS

Pulmonary circulation is a vascular system subject to certain pressure and volume conditions different from the systemic circulation. It is a system of low pressures and resistances, which functions under increased flow conditions and which creates a resistance by ten times lower than the systemic resistance. The pulmonary resistance is quantified according to Ohm's law, by the ratio between the difference of pressure of the pulmonary artery (PAP) and the pulmonary capillary pressure (PCP) and the cardiac output (CO). Its value can be expressed in mmHg/l/min (or Wood units) or converted by multiplication with 80 in order to express the result in dyne.sec.cm$^{-5.}$

RVP = (PAP – PCP)/ (1)

Even under effort conditions, where the

cardiac flow can increase by 5-6 times, the mean PAP does not exceed 20 mm Hg, because of certain adaptive mechanisms which include a great distensibility of the pulmonary artery tree, the low active vasomotricity and the recruitment of new vascular territories, usually closed (process called passive vasodilatation) (1).

The right cardiac catheterization is the reference method for determining the degree of hemodynamic affectation and for testing the pulmonary circulation vasoreactivity. However, the cardiac catheterization is an invasive, expensive method, with potential risks (including vital risks), which is performed only in reference centers. This aspect caused the interest for developing certain alternative techniques of studying the pulmonary hemodynamic parameters. The echocardiography occupies an important role in this research direction. Our study aims at determining the correlation between echocardiographic data and haemodynamic parameters obtained by cardiac catheterization in patients with pulmonary hypertension.

MATERIAL AND METHODS

We conducted a prospective study on 55 patients diagnosed with pulmonary hypertension (PH) over the period 1 November 2008 – 1 November 2011 in "Prof. Dr. George Georgescu" Institute of Cardiovascular Diseases of Iaşi. The pulmonary hypertension was defined as an increase of the mean pressure of the pulmonary artery at 25 mm Hg or more at rest (2). The pulmonary hypertension clinical classification was performed according to Dana Point 2008 classification (2). The echocardiographic examination was performed in maximum 24 hours as compared to the cardiac catheterization, using a Vivid E9 (GE Healthcare) or Acuson Sequoia C512 (Siemens) echocardiograph. All the patients signed an informed consent for the performance of the cardiac catheterization. The echocardiographic examination included the determination of the following parameters:

1. The estimation of the systolic pressure in the pulmonary artery based on the tricuspid regurgitation velocity. In the patients without pulmonary stenosis, the systolic pressure from the pulmonary artery (sPAP) is equal with the systolic pressure from the right ventricle (SRVP). sPAP is determined by calculating the gradient right ventricle – right atrium using Bernoulli simplified equation, plus the pressure from the right atrium (RAP). The right atrium pressure was assessed based on the dimension of the right atrium, on the severity of the tricuspid regurgitation and on the diameter and collapse degree of the inferior vena cava.

$$sPAP = SRVP = 4 \max v\ TR^2 + RAP \quad (2)$$

max v TR = maximum velocity of the tricuspid regurgitation jet

2. The diastolic pressure in the pulmonary artery (dPAP) was assessed using the pulmonary regurgitation.

$$dPAP = 4Vd^2 + RAP \quad (3)$$

Vd = end-diastolic velocity of the pulmonary regurgitation

RAP = right atrium pressure

3. The mean pressure in the pulmonary artery (mPAP) was assessed based on the maximum pressure gradient between the pulmonary artery and the right ventricle at the beginning of diastole.

$$PAPm = 4Ved^2 \quad (4)$$

Ved = early-diastolic velocity of the pulmonary regurgitation

4. The echocardiographic assessment of the pulmonary vascular resistances (PVR) was performed by three different methods:

4.1. Abbas formula is the ratio between the maximum speed of the tricuspid regurgitation flow (max v TR) and velocity – time integral in the ejection tract of the right ventricle (VTI_{RVOT})

$$PVR = \text{max v TR}/ VTI_{RVOT} \quad (5)$$

4.2. Another formula employed, derived from the previous one, is:

$$PVR = \text{max v TR}/ VTI_{RVOT} \times 10 + 0,16 \quad (6)$$

4.3. The third method employed is the ratio between sPAP and the product between VTI_{RVOT} and heart rate (HR):

$$PVR = sPAP/ (VTI_{RVOT} \times HR) \quad (7)$$

The statistic analysis was performed using MedCalc version 12.1.3 (MedCalc Software, Mariakerke, Belgium). The continuous variables were presented as mean ± DS. We calculated Pearson linear correlation coefficient between the results obtained by the two methods.

RESULTS

Our study included 8 patients with idiopathic pulmonary artery hypertension (class 1.1), 1 patient with pulmonary artery hypertension secondary to connective tissue disease (class 1.4.1), 28 patients with congenital cardiopathies (class 1.4.4), 7 patients with PH due to the left heart diseases (class 2) and 11 patients with chronic thromboembolic pulmonary hypertension (class 4). The average age was 48.72 ± 17.67 years old. The sample comprised 30 female patients (54.54%) and 25 male patients (45.45%) (tab. I).

TABLE I

The comparative study of the pulmonary pressures

Parameter	Echocardiography	Catheterization	r	p
sPAP, mm Hg	66.34 ± 24.47	67.86 ± 22.3	0.847	< 0.0001
mPAP, mm Hg	46.24 ± 17.03	48.82 ± 18.4	0.7	<0.001
dPAP, mm Hg	31 ± 14.22	32.85 ± 15.49	0.54	0.01

We compared sPAP calculated on the echocardiography with sPAP obtained at cardiac catheterization. We obtained a strong positive correlation between the two methods (r 0.847, p < 0.0001). We defined measurements' accuracy as a difference smaller than 10 mm Hg between the echocardiography and the cardiac catheterization. We obtained this concordance in 23 patients (45%). The number of underestimations and overestimations was equal (9 patients, 17.64%). The average underestimation degree was 17.77 mm Hg, and the overestimation was of 17.33 mm Hg (p 0.3). Overestimations of more than 20 mm Hg were recorded in 4 patients (7.84%), and underestimations of more than 20 mm Hg in 3 patients (4.22%). sPAP echocardiographic determination allowed the correct framing in severity classes in 49 cases (96%) (fig. 1).

For pulmonary resistance estimation we obtained excellent correlations with the cardiac catheterization, regardless of the method employed (fig. 2, 3, 4). PVR average value at cardiac catheterization was 10.4 ± 5.14 Wood units.

DISCUSSION

The hemodynamic study of the pulmonary circulation has a crucial importance, the pulmonary hypertension diagnostic being established, according to the guides in force, based on a hemodynamic parameter (mPAP). Determining the pulmonary pressures and resistances, besides diagnosis identification, allows the framing in the clinical classes, the selection of the optimal therapeutic scheme and the supervision of the therapeutic response. The exclusive achievement of these desiderata by invasive investigations supposes high costs and the risk of complications. Our study, together with the other recent articles, proves that the echocardiography can represent a method of determining both the pulmonary pressures and resistances. Other studies found very good correlations between sPAP value assessed on the echocardiography and the one measured invasively (r 0.98) (5). sPAP underestimation can be produced by the wrong alignment of the cursor with the jet direction, in patients with severe tricuspid regurgitation (because of the modified geometry of the tricuspid orifice) or very low regurgitation or caused by the precarious echogenicity in patients with chronic pulmonary diseases. In the last two situations, the use of a contrast agent can improve the Doppler signal quality and can increase measurements accuracy (6). sPAP overestimation is possible too. The main explanation is connected to the fact that the echocardiography measures the maximum instantaneous gradient, which is by definition higher than peak to peak gradient measured at the cardiac catheterization. Very recent studies obtained very good results for the mean PAP value deducted from the systolic PAP value based on certain mathematic formulae (7, 8). Using this formula, there was identified a threshold value of 36 - 38 mm Hg of sPAP for the PH diagnosis, corresponding to an mPAP > 25 mm Hg (7). The sensitivity and specificity of the method were excellent (97.9%, respectively 98.6%).

The same excellent correlations were obtained for the pulmonary vascular resistance values; from this point of view, the results of our study frame in the modern tendency of echocardiographic estimation

of the pulmonary resistance (9, 10). The formula that we selected for our study is fast and consistent. The normal value of the ratio max v TR/ VTI_{RVOT} is ≤ 0.15 (11). The ratio max v TR/ $VTI_{RVOT} > 0.2$ identifies with a good sensitivity and specificity a pulmonary vascular resistance higher than 2 Wood units and integrally the pulmonary vascular resistances higher than 4 Wood units (12). A ratio max v TR/ $VTI_{RVOT} > 7.6$ allows the identification of the patients with negative prognostic (11).

CONCLUSIONS

The echocardiography is a reliable method for the study of pulmonary circulation hemodynamics. Even though the echocardiography cannot substitute yet the invasive measurement of the pulmonary vascular resistance especially when it determines a therapeutic decision, the method is very useful in the case of the pulmonary hypertension caused by increased flow (with normal pulmonary resistances) or in advanced stages of the disease, where the systolic pulmonary artery pressure decreases by a reduced cardiac flow, but the pulmonary resistances are high, as for the serial examinations performed during the supervision of the therapeutic response.

ESSENTIAL HYPERTENSION AT YOUNG PEOPLE – AMBULATOR VERSUS HOSPITAL (Abstract): Cardiovascular disease is the leading cause of death in our country. The number of young people with hypertension grow up quickly, so a good control of dyslipidemia and blood pressure (BP) is essential in prevention of cardiovascular disease. **Aim**: To investigate the prevalence of HTA at young people and established the corelation with another risk factors like smoke, colesterol, obesity and heredity, few data are available on the blood pressure characteristics of young patients. **Material and method**: It has been investigate 366 young people between 19-25 years old, in ambulatory system and 350 younger with the same age, in hospital. Blood pressure was measured according to standard procedures, and was considered well-controlled if it was <140/90 mm Hg. **Results**: From our ambulatory patients were 198 women (54,1%), 168 men (45,9%) and from hospital were 178 women (50,9%) and 172 men (41,9%). HTA was present at 37 patients (10,1%) in ambulatory system and 50 patients (14,3%) in hospital. Between the intensity of smoke, the number of cigarette and the prevalence of HTA is a direct relation. The heredity factor is very important, too. The prevalence grow more than 2,5 at this patients. The incidence of HTA is 1,9 bigger at women with big values of colesterol and 2,1 at men with big colesterol. The relation between HTA – obesity is proven in our study, the incidence of HTA is 2,6 bigger at the obeses patients. These arguments should also promote further research in primary care on the control and the therapeutic behavior of the physicians. **Key words**: HYPERTENSION, OBESITY, SMOKE, HEREDITY.

Hipertensiunea arterială esențială (HTA), factor de risc cardiovascular independent, este tot mai frecvent diagnosticată la tineri. Prezența unor valori crescute ale tensiunii arteriale (TA) în copilărie şi adolescență reprezintă un risc pentru HTA a adultului.

Relația pozitivă dintre TA sistolică, TA diastolică şi riscul cardiovascular este recunoscută de multă vreme; această relație este puternică, continuă, graduală, consistentă, independentă şi predictivă atât pentru prezența cât şi în absența cardiopatiei ischemice manifeste (1, 2). În plus, prevalența mare în populație face ca HTA să fie o problemă majoră de sănătate publică (3, 4). La adult valorile crescute ale TA sunt corelate cu riscul apariției infarctului miocardic, accidentului vascular cerebral (stroke), bolilor renale, HTA fiind un factor de risc cardiovascular independent, extrem de im-

portant (5, 6).

În ultima perioadă asistăm la progrese importante legate de diagnosticul şi evaluarea HTA la copil, adolescent şi tânăr. Sub aspectul etiologiei, timp îndelungat s-a afirmat, că la aceste categorii de vârstă domină forma secundară a afecţiunii, dar s-a constatat că HTA esenţială devine gradat etiologia dominantă (7). Prezenţa unor valori crescute ale TA la copil şi adolescent constituie un factor de risc pentru apariţia HTA la adult; numeroase studii relevă fenomenul de tracking, de persistenţă a HTA din adolescenţă la maturitate (8, 9).

Pe lângă prevalenţa mare a HTA, tinerii asociază şi diferite comorbidităţi - dintre acestea pe primul loc se află obezitatea, afecţiune ce are un caracter cu adevărat epidemic la această vârstă (10, 11).

La tineri HTA esenţială îmbracă o formă uşoară sau de gradul I, subiecţii fiind adesea supraponderali sau obezi, ori având antecedente heredocolaterale pozitive pentru HTA sau boala cardiovasculară. Apariţia HTA la vârste tinere are două consecinţe majore: creşterea riscului de boală cardiovasculară şi modificarea stării de sănătate a subiectului în sens negativ. Ca urmare devine importantă evaluarea cât mai corectă şi completă a unui asemenea subiect, dar şi instituirea măsurilor de tratament (12, 13).

Pornind de la cele câteva premise menţionate scopul acestui studiu a fost pe de o parte de a stabili prevalenţa HTA esenţiale la tineri şi pe de altă parte de a evalua corelaţia existentă între HTA şi alţi factori de risc cardiovascular: fumat, hipercolesterolemie, antecedente heredo-colaterale şi obezitate.

MATERIAL ŞI METODĂ

Scopul acestui studiu a fost de a evalua prevalenţa HTA la un lot de 366 tineri cu vârsta cuprinsă între 19-25 ani, ce s-au adresat medicului în ambulator versus 350 tineri spitalizaţi, precum şi de a stabili corelaţiile existente cu alţi factori de risc. Factorii de risc cardiovascular care influenţează puternic prevalenţa HTA la tineri sunt: fumatul, valoarea colesterolului, obezitatea, precum şi prezenţa afecţiunii la părinţi.

Măsurarea tensiunii arteriale a fost efectuată cu tensiometrul cu mercur în spital, respectiv tensiometru de braţ în ambulator, verificat în prealabil. În ambulator, pacientul a fost lăsat minim 15 minute în repaus şi su fost efectuate 3 măsurători, la distanţă de câteva minute. S-a notat valorea medie a determinărilor. Metoda de determinare a valorilor tensionale a fost cea cunoscută; manşeta tensiometrului a fost poziţionată la nivelul braţului, după stabilirea pulsului la nivelul arterei brahiale.

Pacienţii din ambulator au fost împărţiţi în funcţie de sex în 54,1% femei şi 45,9% bărbaţi, iar cei din spital, incluşi în studiu, din aceeaşi categorie de vârstă, au putut fi scindaţi în 50,9% femei şi 49,1% bărbaţi. Nu s-a constatat o diferenţă semnificativă statistic între cele două loturi. Tuturor li s-au determinat parametrii antropometrici (înălţime, greutate, IMC), valorile TA, colesterolul. De asemenea, s-a stabilit statusul de fumător sau nefumător, consumul de alcool, activitatea fizică şi au fost consemnate antecedentele heredocolaterale.

Definirea HTA s-a făcut folosind criteriile indicate în cel de-al IV-lea raport privind diagnosticul, evaluarea şi tratamentul HTA la adolescent şi tineri (14).

REZULTATE

Incidenţa prehipertensiunii şi HTA la lotul studiat este de 13,7% şi respectiv 10,1% la pacienţii din ambulator. Raportul

se inversează în cazul pacienților spitalizați, incidența pacienților cu HTA (14.3%) fiind mai ridicată decât cea a pacienților prehipertensivi (12.6%) (fig. 1).

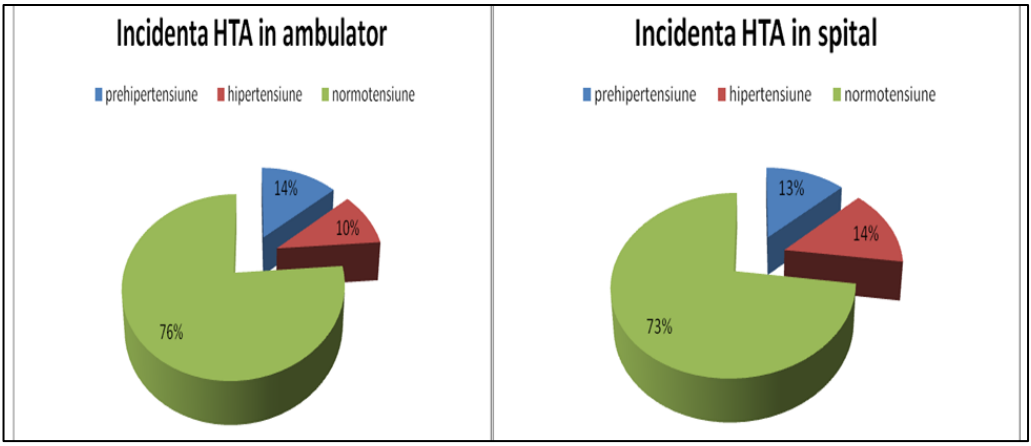

Fig. 1. Incidența prehipertensiunii şi HTA la tineri în ambulator şi spital

În ceea ce privește incidența HTA pe sexe se remarcă o uşoară predominanță a acesteia la sexul masculin 11,2% în ambulator, 10,8% în spital, față de sexul feminin 9,2% ambulator şi 10,6% în spital. Deci, indiferent de modalitate de prezentare la medic numărul pacienților de sex masculin este mai mare decât cel al pacienților de sex feminin, dar aceasta diferență nu este semnificativă statistic.

Rolul fumatului ca factor de risc direct, independent pentru HTA este incomplet elucidat, rezultatele diverselor studii fiind contradictorii (15, 16). La tinerii luați în studiu statusul de fumător sau nefumător nu influențează semnificativ prevalența HTA. În schimb între intensitatea fumatului, exprimată prin numărul de țigarete fumate zilnic şi prevalența HTA există o relație de directă proporționalitate (fig. 2).

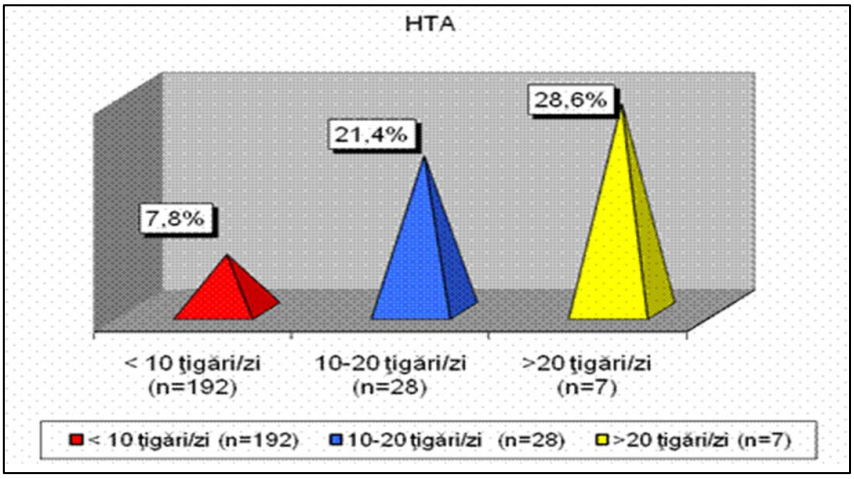

Fig. 2. Incidența HTA în funcție de intensitatea fumatului

Antecedentele heredocolaterale pentru HTA influenţează puternic prevalenţa acesteia la descendenţi. Prevalenţa HTA este de 2-2,5 ori mai mare dacă unul dintre părinţi este hipertensiv şi se triplează dacă ambii părinţi au afecţiunea (fig. 3).

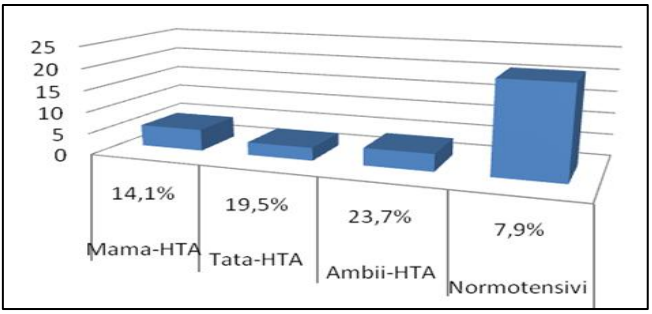

Fig. 3. Incidenţa HTA în funcţie de AHC de boală hipertensivă

O corelaţie cu totul particulară s-a constatat în cadrul relaţiei colesterol - HTA. Incidenţa HTA este de 1,9 ori mai mare la pacientele de sex feminin, cu hipercolesterolemie comparativ cu cele cu valori normale ale colesterolului, iar la sexul masculin incidenţa HTA este de 2,1 ori mai mare la pacienţii cu valori ridicate ale colesterolului (tab. I). Nu s-a constatat o diferenţă semnificativă statistic între cele două sexe. Rezultă deci că hipercolesterolemia este un puternic factor de risc pentru apariţia HTA.

TABELUL I.

Incidenţa HTA în funcţie de valorile colesterolului

	Femei		Bărbaţi		Total	
	Nr.	**% HTA**	**Nr.**	**% HTA**	**Nr.**	**% HTA**
Colesterol total < 180 mg/dl	15	8,4	14	9,6	28	9,0
Colesterol total >180 mg/dl	4	15,6	5	20,0	9	17,9

Relaţia HTA - obezitate este dovedită şi în studiul nostru, incidenţa HTA fiind mult mai mare la hipertensivi faţă de normotensivi – respectiv de 2,6 ori (tab. II). Această diferenţă este semnificativ statistic ($p<0.01$) şi se constată în ambele categorii de pacienţi studiaţi: ambulator sau spital.

TABELUL II.

Prevalenţa HTA în funcţie de statusul ponderal

	Femei			Bărbaţi		
	Nr.	Pondere	Prevalenţă	Nr.	Pondere	Prevalenţă
Normoponderali						
Normotensivi	291	84,3	57,7	213	75,3	42,3
HTA	54	15,7	43,5	70	24,7	56,5
Supraponderali+obezi						
Normotensivi	22	48,9	48,9	23	47,9	51,1
HTA	23	51,1	47,9	25	52,1	52,1

DISCUȚII

Datele din literatură ce fac referire la prevalența HTA la adolescent şi tânăr oferă cifre cuprinse între 1-13%, iar după unii autori procentul poate ajunge şi la 17% (18, 17). Aceste variații foarte mari sunt determinate de criteriile adoptate pentru a defini valorile normale ale TA, numărul determinărilor valorilor TA în cursul unei examinări, numărul examinărilor în timp precum şi de durata urmăririi subiecților în timp. Prevalența HTA a fost de 10,1%, cu o uşoară predominanță la sexul masculin. Este foarte probabil ca rezultatul obținut de noi să ofere o supraevaluare a prevalenței HTA la lotul studiat deoarece nu au fost excluşi subiecții ce ar fi putut prezenta HTA de halat alb (frecvent întâlnită la consultațiile în ambulator) şi nu au fost înlăturate posibilele cauze de HTA secundară.

Se observă prevalența mare a prehipertensiunii echivalent al categoriei high normal la adult şi a cărei depistare constituie indicație de schimbare a stilului de viață (19).

Uşoara prevalență a HTA la sexul masculin a fost explicată prin faptul că la lotul nostru aceştia au fost mai frecvent obezi şi fumători.

Faptul ca incidența HTA este cvasiegală, indiferent de statusul de fumător sau nefumător s-a explicat prin faptul că vechimea acestui obicei nu e foarte mare în rândul tinerilor şi ca urmare efectele sale pe termen lung (disfuncția endotelială, creşterea rezistenței vasculare periferice, stimularea proliferării celulelor musculare netede şi creşterea nivelului de endotelină) nu sunt manifeste. Celălalt aspect constatat şi anume creşterea prevalenței HTA cu numărul de țigări fumate zilnic s-ar putea explica prin efectele acute (în principal stimularea simpatică) care domină la adolescenți şi tineri. Rezultate similare între prevalența HTA şi intensitatea fumatului au fost obținute şi în alte studii (20).

Influența antecedentelor heredocolaterale în apariția afecțiunii la descendenți este o certitudine, fiind relevată în numeroase studii. Se apreciază că în apariția HTA esențiale predispoziția genetică are o contribuție medie între 20 şi 60-70% (21).

Relația dintre nivelul colesterolului şi incidența HTA reprezintă o corelație cu totul particulară pe care am observat-o şi vine să sublinieze necesitatea determinării valorii acestuia ori de câte ori tânărul este găsit ca având valori crescute ale TA, lucru subliniat de altfel în ghidul de evaluare a dislipidemiilor, indiferent de vârstă (23, 22).

Relația HTA-obezitate este dovedită de numeroase studii, HTA fiind de altfel componentă a sindromului metabolic din ce în ce mai frecvent diagnosticat la tinerii obezi, hiperinsulinismul şi insulinorezistența fiind una dintre căile patogenetice care realizează legătura dintre cele două afecțiuni (24, 25).

CONCLUZII

1. Prevalența HTA esențiale este în continuă creştere la tineri, devenind etiologia dominantă.

2. Prevalența este puternic influențată de modul de definire a valorilor normale, tehnica şi durata urmării în timp a subiecților.

3. La tineri HTA esențială îmbracă o formă uşoară sau de gradul I.

4. Numărul de țigarete fumate zilnic influențează valorile tensionale.

5. Hipercolesterolemia este un puternic factor de risc pentru apariția HTA.

6. Obezitatea este un alt factor de risc dovedit în apariția şi creşterea valorilor tensionale.

NOUTĂȚI

EFECTELE ANTI-RETROVIRALE ALE AGONIŞTILOR CB2

Drogurile canabinoide au efecte terapeutice la pacienţii aflaţi în stadiul SIDA, „marijuana medicală" fiind utilizată în tratamentul durerii şi caşexiei la aceşti pacienţi. Receptorii canabinoizi CB2, dar nu şi CB1, de pe suprafaţa celulelor imune, pot influenţa răspândirea HIV-1, având în plus, efecte antivirale. Agoniştii canabinoizi CB2 modulează funcţia co-receptorului CXCR4 şi blochează procesul de semnalizare responsabil de pătrunderea virusului în celule, împiedicând infectarea unor noi limfocite T CD4+. Utilizarea agoniştilor CB2-selectivi ca tratament adjuvant în SIDA poate ameliora simptomatologia pacientului şi preveni răspândirea virusului, fără efectele nedorite determinate de administrarea marijuanei şi asociate stimulării receptorilor CB1. (Costantino CM, Gupta A, Yewdall AW, Dale BM, Devi LA, et al. Cannabinoid Receptor 2-Mediated Attenuation of CXCR4-Tropic HIV Infection in Primary CD4+ T Cells. *PLoS ONE* 2012;7(3): e33961. doi:10.1371/journal.pone.0033961).

ADVERSE EFFECTS OF CHOLINESTERASE INHIBITORS IN THE ELDERLY PATIENT WITH MYASTHENIA GRAVIS. CASE REPORTS (Abstract). Myasthenia gravis (MG) is an autoimmune neuromuscular disease caused by the blockade of acetylcholine receptors at the post-synaptic neuromuscular junction. The clinical signs of MG are obvious in the young patient, but they may be misinterpreted in an elderly person with comorbidities either as manifestations of sarcopenia, as the onset of a minor stroke or "equivalents" of acute coronary syndrome or heart failure. Anticholinesterases (Pyridostigmine, Neostigmine) increase acetylcholine concentration at the neuromuscular junction and are the standard agents for symptomatic treatment; in elderly patients, their side-effects can easily be attributed to other age-related problems, such as bradycardia, arrhythmia or epigastric pain and nausea. We present two cases that illustrate the particularities of diagnosing and treating elderly patients with comorbidities and MG. We conclude that it is necessary to periodically monitor the elderly patient with MG for the early identification of adverse effects. It is also useful to remember that in the elderly patient with comorbidities and MG the risk of cholinesterase inhibitor overdose is increased, partly due to numerous concomitant drugs and partly due to low therapy adherence. Both statins and associated metabolic diseases are possible causes of disease progression, therefore caution is required in prescribing medication to the patient with myasthenia gravis. **Keywords:** CHOLINESTERASE INHIBITORS SIDE EFFECTS, MYASTHENIA GRAVIS, ELDERLY.

Myasthenia gravis (MG) is an autoimmune neuromuscular disease caused by the blockade of acetylcholine receptors at the post-synaptic neuromuscular junction, inhibiting the effects of acetylcholine on nicotinic receptors. Clinical manifestations of MG are varying degrees of weakness of skeletal muscle and/or muscles that control eye movements, facial expression, swallowing (1). Life expectancy of these patients is like that of the general population, and, as the population ages, estimates indicate that the number of elderly patients with MG will significantly increase. Anticholinesterases (Pyridostigmine, Neostigmine) increase acetylcholine concentration at the neuromuscular junction and are the standard agents for symptomatic treatment (2, 3).

The clinical signs of MG are obvious in the young patient: drooping eyelid, double vision, chewing and swallowing difficulties,

decrease in limb muscle strength. However, the same symptoms occurring in an elderly person with comorbidities may be misinterpreted by the physician either as manifestations of the aging phenomenon (reduced muscle strength is the cardinal feature in sarcopenia), or as the onset of other conditions that are more frequent in the elderly (transient ischemic attack, minor stroke) or "equivalents" of concomitant chronic diseases (acute coronary syndrome, heart failure) (4, 5). If the elderly patient was diagnosed with MG years ago and was properly treated, there is a greater probability that the side effects of medication will interfere with the progression of some concomitant conditions, especially cardiovascular, thus accounting for the symptoms and changes reported by the patient for which we either do not find an explanation, or the explanation we find is deeply erroneous. For this reason, minimal medication and careful and sustained monitoring of treatment is recommended in elderly MG patients (3,6).

We report two cases of elderly patients with MG which illustrate the adverse effects of treatment with neostigmine at therapeutic doses and the consequences of neostigmine overdose at the time of diagnosis and treatment initiation.

CASE REPORTS

Case 1. A 64-year-old female patient diagnosed with ocular MG 26 years ago, for which she followed a symptomatic treatment with cholinesterase inhibitor neostigmine at the therapeutic dose of 15mg x 2/day. She associated a cardiovascular condition, namely grade 3 essential hypertension, for which she received treatment with angiotensin converting enzyme inhibitor and thiazide-like diuretic. The patient also had a history of operated right ear mastoiditis with secondary hearing loss and peripheral vertiginous syndrome, being on treatment with betahistine.

Under the afore-mentioned treatment, the patient, although asymptomatic, detected by self-monitoring low heart rates for about one month before presentation to her attending physician. Resting electrocardiogram revealed sinus bradycardia 50/min, and 24-hour Holter EKG monitoring revealed a mean heart rate of 57/min with a minimum value of 37/min and a maximum of 108/min, with no sinus pause > 2,500 msec. Of note, the patient was not taking drugs inducing bradycardia. The biological profile revealed normal thyroid status, and bilateral reduced muscle strength in the upper limbs. Following the assessment of the recently occurred bradycardia, we considered the possible occurrence of side effects to chronic neostigmine treatment, and the patient was referred to a neurologist for the reassessment of therapeutic options. Ideally, this re-evaluation should be done in the presence of both physicians for optimal approach.

Case 2. A 74-year-old male patient known with important comorbidities (grade 3 essential hypertension, paroxysmal atrial fibrillation, chronic ischemic cardiomyopathy, associated with type 2 diabetes and amiodarone-induced hypothyroidism), for which he received multiple drugs (antiarrhythmic, chronic oral anticoagulation, antihypertensive, antidiabetic, hormone replacement, coronary dilation, and statin - rosuvastatin 5mg/day - therapy), presented in the out-patient geriatric clinic for epigastric pain and nausea. In the last two months he was diagnosed with late-onset seropositive MG (high anti-acetylcholine receptor antibody levels) that presented with important myalgia and muscle fatigue; the clinical examination revealed right palpebral ptosis. The patient was assessed by a neurologist and treatment with Pyridostigmine 60 mg x 3/day was initiated. Later,

another cholinesterase inhibitor, namely Neostigmine 15 mg x 3/day was recommended as an alternative. For reasons of noncompliance, the patient continued the treatment with both these drugs for 10 days and presented to the internist for overdose phenomena, represented by epigastralgia and nausea. A new neurological consultation was recommended, with the readjustment of therapeutic regimen to Neostigmine 15mg x 3/day and corticotherapy.

DISCUSSION

As to the age of onset of MG there is a bimodal distribution, with a predominance for women in decades 3-4 of life and for men in decades 4-8, respectively. At advanced ages (diagnosis after age of 50), MG is more common in males, and diagnostic confusions are also more frequent. The here-reported cases illustrate both situations and fall within the epidemiological characteristics cited in the literature (1, 7, 8).

MG requires long-term treatment with cholinesterase inhibitors, which can cause bradycardia and even asystole (9). The symptomatic benefit of both Pyridostigmine and Neostigmine is due to the increase in acetylcholine concentration at the neuromuscular junction through the nicotinic effect at this level. However, cholinesterase inhibitors have muscarinic side effects at the cardiac level, most frequently bradycardia induced by M2 cardiac receptor overload (10). In Case 1 bradycardia occurred after a long period of Neostigmine treatment. Although the patient may be asymptomatic, bradycardia may progress to atrioventricular blocks of varying degrees, so monitoring for treatment efficacy and adverse effects in case of long-term administration is required. There are literature data on Pyridostigmine-induced high-grade atrioventricular blocks which required pacemaker insertion (9). Of the cholinesterase inhibitors, Pyridostigmine is the safest due to the reduced rate of muscarinic adverse effects compared to Neostigmine (11), but its availability in Romania is reduced. The most effective alternatives are corticotherapy and immunosuppressive agents (2, 12).

Age, and not the duration of treatment with cholinesterase inhibitors, correlates with the incidence of cholinergic side effects. Among the most common muscarinic side effects of cholinesterase inhibitors are gastrointestinal disorders, including cramps or abdominal pain, as expression of autonomic dysfunction (3, 11). Overdosage induces a moderate cholinergic crisis (expressed as muscle weakness and exacerbation of gastrointestinal adverse effects), this being the case of the second patient we presented (13). For reasons of noncompliance, possibly due to polymedication, the patient had self-administered supratherapeutic doses. Frequent monitoring for adverse effects is required because the cholinergic crisis is difficult to differentiate from worsening of myasthenia gravis (14).

Statins are also mentioned in the literature as possible triggers of disease exacerbation in the elderly. Thus, Gale (15) reports a rare side effect of statins, namely the induction or worsening of autoimmune diseases, myasthenia gravis included. Statins are drugs often prescribed because of their important role in cardiovascular disease prevention. On one hand, statin treatment may aggravate the MG symptoms due to statin-induced myopathy, but on the other hand there are documented cases of seropositive MG secondary to statin therapy. Also, the metabolic disorders are cited among the factors that precipitate the worsening of MG symptoms (5). In Case 2, the patient followed a treatment with Rosuvastatin, was diabetic and was on hormone replacement therapy for amiodarone-induced hypothyroidism. All these factors

are elements that can aggravate symptoms, but also cause management difficulties due to comorbidities (15).

CONCLUSIONS

With these cases we underline the necessity of periodical monitoring of patients with cholinesterase inhibitors treatment for early identification of adverse effects. Cholinesterase inhibitors are the major symptomatic treatment of MG. However, long-term administration in therapeutic doses may cause adverse effects in vulnerable population groups.

Also, we draw attention to the fact that in the elderly patient with comorbidities the risk of cholinesterase inhibitor overdose is increased. Polymedication favors reduced compliance, which can lead to a cholinergic crisis. This situation is more delicate as the worsening of MG symptoms can mimic a cholinergic crisis.

Both statins and associated metabolic diseases are possible causes of disease progression, therefore caution is required in prescribing medication to the patient with myasthenia gravis and a correct treatment of associated diseases.

ANTIBIOTIC THERAPY IN THE INFECTED DIABETIC FOOT (Abstract): Foot infections in patients with diabetes cause substantial morbidity and may lead to amputation of a lower extremity. Management of diabetic foot infections involves evaluating and determining the severity of infection as the basis for selecting the appropriate approach to antibiotic treatment. **Aim:** The purpose of our study is to analyse the etiologic agents commonly involved in diabetic foot infections and to appreciate the outcome of these infections with antibiotic therapy. **Material and methods:** We included 90 patiens with infection of the diabetic foot, admitted in the Diabetes Clinic, „Sf. Spiridon" Hospital; wound swabs were collected from 79 infected ulcers. The seriousness of the infection was assesed using the IDSA clinical classification. **Results:** 45% of the infections were monomicrobial (typically with gram-positive cocci), but we also found gram-negative rods and enterococci. Initial therapy was usually empiric, while definitive therapy is based on the results of culture and sensitivity tests, as well as the clinical response to empiric therapy. **Conclusions:** The effectiveness of the antibiotic therapy, based on the clinical evolution and the absence of surgical intervention is related to the presence or absence of ischaemia and other diabetes-related complications rather than to the microorganism itself; antibiotics are a crucially important adjunct in the complex therapy of the diabetic foot. **Key words:** DIABETIC FOOT ULCERS, INFECTION, ANTIBIOTICS

Ulcerele piciorului diabetic sunt o serioasă problemă de sănătate. Statisticile arată că 15% din populația diabetică are pe parcursul vieții ulcerații la nivelul picioarelor (1). Ulcerele sunt rezultatul neuropatiei sau ischemiei. Neuropatia periferică se caracterizează prin scăderea senzațiilor protective si modificări biomecanice care produc ulcerații în zonele de presiune. Neuropatia autonomă determină scăderea secreției sudorale şi modificări vaso-motorii care vulnerabilizează tegumentele la injurii. Ischemia este datorată bolii arteriale periferice. Tulburările circulatorii în zona ulcerativă sunt asociate cu reducerea oxigenării şi nutriției şi scăderea şanselor de vindecare a ulcerației. Țesuturile necrotice sunt un bun mediu de creştere a bacteriilor şi au mecanisme de aparare la infectii scăzute. Infecțiile care de obicei complică ulcerele piciorului diabetic sunt de cele mai multe ori consecința şi nu cauza ulceraților. Complicațiile acestor ulcere sunt principalele cauze de spitalizare si amputații la pacientii diabetici (2). Tratamentul antibiotic sistemic este totdeauna indicat la pacienții cu ulceratii infectate. Obiectivul lucrării de față este de a analiza patogenii cei mai frecvent implicați în infecțiile piciorului

diabetic, severitatea acestor infecţii, corelaţia cu factorii de risc prezenţi (cel mai frecvent complicaţii asociate diabetului) şi evoluţia infecţiilor piciorului diabetic la tratament antibiotic

MATERIAL ŞI METODE

Lotul studiat a fost format din pacienţii internaţi în Clinica de Diabet, Nutriţie şi Boli Metabolice Iaşi în perioada 1.01.2010 – 31.12.2010 cu diagnostice în relaţie cu "piciorul diabetic". Am realizat un studiu retrospectiv, realizând o bază de date cu următoarele informaţii despre pacienţii studiati: date generale (sex, vârstă, mediul de proveniență, durata spitalizării), informaţii referitoare la nivelul de şcolarizare, indici antropometrici [greutatea(G), înălţimea(T) şi circumferinta abdominală (CA); s-a calculat indicele de masă corporală [(IMC) = $G(kg)/T^2(m^2)$]

Informaţii despre diabetul zaharat (tipul de diabet zaharat, tratamentul efectuat, controlul diabetului zaharat (valoarea HbA1c la internare) prezenţa complicaţiilor cronice specifice.

Informaţii despre ulceraţia prezentă : tipul leziunii (ulceraţie, gangrenă, altele), localizarea leziunii (la nivelul degetelor, la nivel plantar, altele), clasificare (Texas, PEDIS, IDSA)

Informaţii despre prezenţa infecţiei confirmată prin culturi pozitive şi/sau prin semne locale de infecţie (celulită, osteoliză pe radiografie) şi/sau prin semne generale de infecţie (febră, leucocitoză).

Informaţii despre tratamentul antibiotic sistemic si evoluţia ulceraţiei Am luat in evidenţa tipul şi durata tratamentului antibiotic şi de asemenea, evoluţia spre amputaţie, evidenţiată prin necesitatea transferului într-o clinică chirurgicală.

Datele au fost colectate în programul Windows Office Excel 2007, în care s-a realizat şi prelucrarea statistică.

REZULTATE ŞI DISCUŢII

În Clinica de Diabet zaharat, Nutriţie şi Boli Metabolice (DNBM) au fost 90 internări în anul 2010 (4,5% din total internări) pentru diagnostice legate de "piciorul diabetic". Dintre acestea, 68 au fost bărbaţi (79,1%), iar 22 au fost femei (20,9%). Media vârstei la bărbaţi a fost 60,68 ani; media vârstei la femei a fost 63,64 ani. Din mediul rural proveneau 49 pacienţi (54,4%). În ceea ce privesc studiile pacienţilor: un pacient (1,1%) a fost fără studii; 11 pacienţi (12,2%) au declarat 4 clase; 35 de pacienţi (38,8%) aveau gimnaziul; 10 pacienţi (11,1%) aveau şcoală profesională; 23 pacienţi (25,5%) aveau liceul; 1 pacient (1,1%) avea şcoală post-liceală; 4 (4,4%) aveau studii superioare; la 5 pacienţi nu s-a specificat nivelul de instruire

În funcţie de IMC, s-a constatat că: un pacient (1,1%) era subponderal; 16 pacienţi (17,7%) erau normoponderali; 28 de pacienti (31,1%) erau supraponderali, iar 31 de pacienţi (34,4%) erau obezi; la 14 pacienţi (15,5%) nu s-au măsurat indicii antropometrici. 9 pacienţi (10%) aveau CA normală, 81 de pacienţi (90%) aveau CA groasă (>94 cm la barbati şi > 80cm la femei). Durata medie a spitalizării în Clinica DNBM a fost de 14,72 zile, cu un maximum de 55 zile şi un minimum de o zi. Mai puţin de 7 zile de spitalizare au avut 14 pacienţi (15,5%); între 7-13 zile de spitalizare au avut 34 pacienţi (37,7%); 23 pacienţi (25,5%) au stat internaţi între 14-20 zile; 10 pacienţi (11,1%) au stat internaţi între 21-27 zile; 9 pacienţi (10%) au stat internaţi peste 28 zile.

În ceea ce priveşte tipul de diabet zaharat, 7 pacienţi (7,7%) aveau DZ tip 1, 82 de pacienţi (91,2%) aveau diagnostic de DZ tip 2 şi un pacient (1,1%) avea diagnostic

de DZ secundar pancreatic. 63 dintre pacienți (70%) urmau tratament cu insulină la momentul internării. Doar 5 pacienți (6,8%) au avut $HbA_{1c} \leq 7\%$, media HbA_{1c} pe intregul lot fiind de 9,68%. Luând în considerare complicațiile cronice specifice diabetului zaharat cu răsunet asupra piciorului, mai exact polineuropatia periferică senzitivo-motorie (PNPSM) şi arteriopatia obliterantă a membrelor inferioare (AOMI), s-a constatat că: 3 pacienți (3,3%) nu prezentau nici una dintre aceste complicații; 3 pacienți (3,3%) prezentau numai AOMI (std. IV); 84 de pacienți (93,3%) aveau PNPSM, dintre aceştia 29 (32,2%) aveau şi AOMI, (25 pacienți prezentau chiar AOMI std. IV, adică 27,7%). Complicațiile cronice microvasculare specifice diabetului zaharat au fost prezente după cum urmează: 54 de pacienți (60%) prezentau retinopatie diabetică (RD), dintre care 16 cu formă proliferativă (17,7%). Dintre cei cu RD, 22 aveau şi nefropatie diabetică (ND), adică 40,7% din cei cu RD. S-a mai întâlnit ND la 11 pacienți fără RD. În total, ND a fost prezentă la 33 pacienți (36,7%).

Leziunile/ulcerele s-au situat: 35 la nivelul degetelor, 7 la nivelul degetelor şi plantar, iar 46 la nivel plantar. Prezentau celulită 36 dintre pacienti (40%). Secrețiile s-au recoltat în marea majoritate a cazurilor cu un tampon steril şi doar la cazuri selectate s-a dat spre cultură țesut debridat, aspirat purulent sau material bioptic. Secrții s-au putut recolta de la 79 dintre pacienți: 7 au fost negative, restul au fost pozitive (72 de cazuri). Totuşi, între cele 18 cazuri în care nu s-a evidențiat prezența infecției în cultură, în 16 s-a pus diagnosticul de infecție pe criterii clinice, locale (prezența celulitei) şi generale (febră şi/sau leucocitoză). În doar 2 dintre cele 90 de cazuri internate nu a existat infecție, fiind vorba de o ulcerație deget şi un mal perforant plantar neinfectate. 27 de pacienți (30%) mai avuseseră amputații în antecedente.

S-a izolat un singur microorganism în 60 dintre culturi, 2 microorganisme în 10 probe recoltate din plagă şi trei microorganisme într-un singur caz. Dintre cocii gram pozitivi: *S. aureus* a fost identificat drept agent unic în 32 cazuri(45 %); în 6 cazuri (8 %) a făcut parte din agenții patogeni ce cauzau o infecție polimicrobiană. In 27 de culturi s-au izolat stafilococ auriu meticilino-rezistent (SAMR). Stafilococi coagulazo-negativi au fost identificați în 2 cazuri. Streptococi β-hemolitici au fost identificați drept agent unic în 2 cazuri (grup A & G) şi în asociere cu alte microorganisme într-un caz (grup B). Enterococii au fost prezenți în 8 plăgi (11,26%); toate speciile izolate prezentau sensibilitate păstrată la vancomicină. Bacili gram-negativ au fost prezenți după cum urmează: Enterobacteriacee*: Klebsiella pneumoniae* – 10 cazuri, *Proteus* spp. – 6 cazuri, *Escherichia coli* – 3 cazuri, *Morganella* spp.– 2 cazuri, *Serratia* spp – 2 cazuri, *Enterobacter* spp – 3 cazuri, *Citrobacter* – un caz. *Pseudomonas aeruginosa* a fost prezent în 4 cazuri.

Clasificarea severității infecției a arătat că 88 din pacienții din lotul de studiu prezentau semne clinice de infecție, uşoară în 11% dintre cazuri, moderată în 40 % dintre cazuri şi severă în 49 % dintre cazuri. Numai 15 pacienți au avut febra (16,6%). La 20 de pacienți s-au recoltat hemoculturi(HC), la toți cei febrili, dar nu numai, la 5 pacienti HC fiind pozitive (3 dintre acestea la pacienți care nu erau febrili!). Doar 49 pacienți (54,4%) au avut leucocitoză (GA>10000/mmc), 56 (62,2%) au avut neutrofilie. Conform clasificării Texas: 15 sunt BI (16,6%), 32 sunt BII (35,5%), 8 sunt BIII (8,9%), unul este CI (1,1%), 8 sunt DI (8,9%), 16 sunt DII (17,7%), 8 sunt DIII (8,9%), la 2 nu s-a calculat (2,2%).

După clasificarea PEDIS, 16 pacienți (17,7%) sunt clasa *2*, ("*uşoară*" în IDSA), 47 (52,2) sunt *3*, ("*moderată*" în IDSA), 25 (27,7%) sunt *4*, ("*severă*" în IDSA).

Numărul mediu al zilelor de tratament antibiotic injectabil a fost de 12,6 zile. În principiu, numărul de zile de spitalizare se corelează cu numărul de zile în care a fost necesar tratament antibiotic injectabil. 37 de pacienți (42%) au primit un singur antibiotic, restul au primit, alternativ sau concomitent: 2 antibiotice – 30 de pacienți (34%), 3 antibiotice – 11 pacienți, 4 antibiotice – 9 pacienți. 25 pacienți (27,7%) au fost transferați în clinici chirurgicale pentru amputație limitată, 3 pacienți la chirurgie plastică pentru grefă de piele, 3 la chirurgie vasculară pentru revascularizare, 4 în alte clinici pentru probleme grave apărute pe durata spitalizării (cardiologie, neurologie, boli infecțioase).

Am comparat sublotul de pacienți care prezenta numai PNPSM (fără AOMI), cu cel al pacienților care prezenta şi AOMI. Proporția de bărbați a fost mai mare în grupul cu AOMI: 78,1% bărbați în grupul cu AOMI *vs.* 74,1% bărbați în grupul fără AOMI. Media de vârstă a celor din grupul cu AOMI a fost mai mare decât a celor din grupul fără AOMI: la bărbați 63,7 ani în grupul cu AOMI *vs.* 59,1 ani în grupul fără AOMI, iar la femei 65,5 ani la cele cu AOMI *vs.* 63,1 ani în grupul fără AOMI. Ponderea pacienților cu diabet zaharat tip 2 a fost mai mare în grupul cu AOMI (93,8%) față de cei fără AOMI (89,7%).

Au existat diferențe semnificative şi în ceea ce priveşte localizarea leziunilor. Astfel, leziunile la nivelul degetelor au fost mult mai frecvente în rândul celor care prezentau AOMI (65,7%), față de 36,2% la cei care prezentau numai PNPSM. În schimb, leziunile plantare au fost mult mai frecvente la cei cu PNPSM (63,8%), față de 46,9% la cei cu AOMI. Deci, se poate confirma că pacienții cu AOMI dezvoltă mai ales leziuni distale, spre deosebire de cei care prezintă numai PNPSM, care dezvoltă mai ales leziuni plantare.(3) şi cu spectru microbiologic diferit. (4). Astfel, cel mai frecvent patogen întâlnit la cei cu PNPSM a fost SAMR (38,3%), în timp ce la cei cu AOMI au existat 2 patogeni aproape la fel de des întâlniți, şi anume SAMS (21,9%) şi *Klebsiella pneumoniae* (18,8%). Numărul zilelor de tratament antibiotic intravenos a fost uşor mai mare în cazul celor cu PNPSM (13,5 zile) față de cei cu AOMI (11,1 zile), dar numărul de antibiotice folosit a fost acelaşi în cazul celor cu PNPSM şi a celor cu AOMI (în medie 1,9, respectiv 1,8 antibiotice). În concordanța cu datele din literatură, cel mai frecvent au fost implicați cocii gram-pozitivi aerobi; dintre aceştia, *S. aureus* a fost identificat drept agent unic în 45 % din cazuri, iar mai mult de 2/3 dintre tulpini fiind meticilino-rezistente. Deşi este uneori dificil de stabilit dacă microorganismele identificate, în acest caz stafilococii, sunt agenții etiologi sau doar colonizanți ai plăgii (neexistând nicio metodă care să poată indica agentul etiologic sau agenții colonizanți într-o cultură în care s-au obținut mai multe specii), prezența semnelor clinice şi paraclinice de infecție, uneori neidentificarea altor microorganisme şi chiar pozitivarea în 2 cazuri a hemoculturilor duce la considerarea stafilococilor agenți etiologici ai infecției piciorului diabetic în aceste cazuri. Identificarea S. aureus în plagă, fie ca agent unic, fie ca parte a unei flore mixte, implică în primul rând luarea unei atitudini terapeutice imediate, respectiv inițierea de urgență a antibioterapiei. În afară de managementul infecției piciorului diabetic, trebuie evaluată atitudinea față de portajul cronic de SAMR (5).

La majoritatea pacienților s-a inițiat o terapie empirică, a cărei alegere a fost influențată de mai mulți factori: estimarea

complianţei pacientului la un anumit tratament (mod de aministrare, numărul dozelor parţiale etc), istoricul de reacţii alergice la anumite antibiotice sau clase de antibiotice, efectele secundare şi reacţiile adverse (în special în administrarea orală), siguranţa administrării şi posibilitatea unei externări mai rapide (în special la administrarea parenterală), posibilitatea apariţiei rezistenţei, în special riscul de colonizare cu SAMR, riscul apariţiei diareei cu *C. difficile*, costurile asociate antibioterapiei. De asemeni s-a luat în considerare şi disponibilitatea anumitor antibiotice, care poate fi restricţionată prin lipsă sau urmare a dificultăţilor în administrare (6).

Nevoia frecventă de a iniţia tratament empiric în infecţiile piciorului diabetic poate determina alegerea unui regim cu spectru fie prea îngust ca să fie eficient, fie inutil de larg, care ar putea contribui la selecţia unor microorganisme rezistente. Monoterapia pare să fie mai avantajoasă decât asocierile de antibiotice: este mai uşor de administrat, are costuri mai reduse şi scade riscul apariţiilor reacţiilor adverse (7). Pe de altă parte, asocierile de antibiotice pot acoperi o gamă mai larga de microorganisme (având moduri de acţiune diferite, posibil efect sinergic); sunt indicate în infecţiile cu germeni rezistenţi, cum ar fi *P. aeruginosa.* Asocierea antibioticelor reduce deasemenea riscul de apariţie a rezistenţei. Nu exista date suficiente care să recomande asocierea de rutină a antibioticelor pentru a preveni emergenţa rezistenţei, dar această abordare este indicată la iniţierea antibioterapiei empirice la pacienţii cu afecţiuni severe, care au un risc crescut de a avea infecţii cu microorganisme multidrog-rezistente. Când au fost disponibile rezultatele investigaţiilor de laborator, inclusiv a culturii şi antibiogramei, s-a reevaluat terapia antibiotică. Este de preferat alegerea unor agenţi ţintiţi, dacă este posibil cu spectru redus; dar trebuie luat în considerare şi răspunsul clinic la tratamentul iniţial, empiric. Dacă s-a observat regresia semnelor clinice de infecţie, pacientul a tolerat terapia şi plaga a evoluat spre vindecare, nu a mai fost nevoie de remaniere, chiar dacă unele sau toate microorganismele izolate sunt rezistenţi la antibioticul prescris iniţial. Dacă infecţia nu a avut o evoluţie favorabilă, tratamentul a necesitat reevaluare, astfel încât să se obţină un spectru care să acopere toate microorganismele izolate. Dacă infecţia a continuat să evolueze nefavorabil, în ciuda sensibilităţii bacteriilor izolate la antibioticele prescrise, s-a considerat oportună intervenţia chirurgicală sau/şi posibilitatea existenţei unor bacterii ce necesită medii speciale de cultivare. În cazul infecţiilor polimicrobiene, cu evoluţie severă, s-a instituit de la început antibioterapia cu spectru larg cu administrare intravenoasă (8). Antibioticul singular sau în asociere a fost ales să fie activ atât pentru agenţii Gram pozitv, cât şi pentru Gram negativ (*Enterobacteriaceae, P aeruginosa*) şi pe organismele strict anaerobe (peptococi, peptostreptococi, *Bacteroides*). În infecţiile moderate, s-au administrat fluorochinolone în asociere cu clindamicină, iar în infecţiile severe s-a administrat piperacilină-tazobactam sau imipinem-cilastatin. Există studii care au arătat eficienţa ertapenemului *vs* piperacilină tazobactam (9), la fel, unele studii au demonstrat că linezolidul este mai puţin eficient decăt unele βlactamine asociate cu inhibitori de βlactamază, cu spectru mai larg (10). La orice grad de severitate a infecţiei, s-a evaluat riscul implicării SAMR, pentru a lua în considerare fie folosirea agenţilor eficienţi pentru această infecţie (linezolid, vancomicina, daptomicină) fie folosirea unora care nu au fost primit această indicaţie, dar a caror utilizare s-a dovedit în mod repetat eficientă (teicoplanin, acid fusidic, doxiciclină sau trimetoprim-sulfametoxazol), posibil în combinaţie sau asociaţi cu rifampicina

(care nu trebuie niciodată folosită ca monoterapie). În ciuda inițierii precoce a terapiei cu administrare de antibiotice parenteral, uneori folosind asocierile, 25 de pacienți (27,7 %) din lotul cercetat au necesitat transfer într-o secție chirurgicală în vederea amputației; procentul destul de ridicat este probabil influențat şi de gradul de severitate al infecției, rezultate concordante cu datele din literatură, care arată că pacienții diabetici care dezvoltă o infecție la nivelul piciorului au o probabilitate de a necesita amputație de aproximativ 30 de ori mai crescută (11) Terapia cu antibiotice a fost aleasă inițial empiric, în unele cazuri existând o remaniere ulterioară, calea de administrare fiind cea injectabilă. Fluorochinolonele (ciprofloxacina) a fost administrată în terapie unică la 20 (22,2 %) dintre pacienți, alți 46 (51,1 %) primind fluorochinolone în asociere cu cefalosporine de generația a 3–a, metronidazol, glicopeptide, linezolid.

CONCLUZII

Toți pacienții din lotul studiat aveau infectii ale piciorului de severitate medie sau grava care au necesitat spitalizare între 1 şi 55 zile (media 14,72 zile) S-a izolat un singur microorganism în 60 dintre culturi, 2 microorganisme în 10 probe recoltate din plagă şi trei microorganisme într-un singur caz. La pacienții cu ulcerații pe teren neuropat, cel mai frecvent patogen, a fost SAMR, iar la infecțiile pe picior diabetic arteriopat au fost izolați SAMS şi *Klebsiella pneumoniae*. Toti pacienții au primit tratament antibiotic inițial cu spectru larg, ulterior după rezultatele antibiogramei. Din experiența noastră cel mai util antibiotic s-a arătat a fi ciprofloxacina dat inițial empiric, dar care a fost în 72% din cazuri recomandat şi de sensibilitatea aratată de antibiogramă.

RELEVANCE OF L-TYPE CALCIUM CHANNELS FOR THE NON-GENOMIC EFFECTS OF ESTRADIOL AND ALDOSTERONE UPON CONTRACTILE ACTIVITY IN ISOLATED ARTERIES (Abstract): Non-genomic vascular effects of steroids are incompletely understood, despite progress made regarding some aspects, such as the mechanism of endothelium-dependent relaxation by estrogens. **Aim**: To investigate the involvement of certain mechanisms in the rapid, non-genomic effects of estradiol (EST) and aldosterone (ALD) on endothelium-dependent and -independent vasomotor responses. Material and methods: Isometric myography of rings from aorta, mesenteric arch, and first order mesenteric branches isolated from male Wistar rats was used. **Results**: We found that L-type calcium channels (Cav1.2) are important for endothelium-independent relaxation induced by EST, while ALD reduces the involvement of Cav1.2 in phenylephrine-induced contraction and potentates both NO- and EDHF-mediated endothelium-dependent relaxation. To further examine the relevance of Cav1.2 for the vascular effects of EST and ALD, we were using rings with and without functional endothelium, precontracted by direct activation of Cav1.2 (Bay K 8644), high extracellular K+, phenylephrine, and under complete Cav1.2 block (nifedipine). Data suggest that EST, which directly inhibits Cav1.2 in transfected HEK cells, uses mainly this path to induce endothelium-independent relaxation, and that ALD may induce a rightward shift in the voltage-dependence of Cav1.2. **Key words**: SMOOTH MUSCLE, L-TYPE CALCIUM CHANNELS, ESTRADIOL, ALDOSTERONE.

Prezente în diferite tipuri de celule, canalele de calciu de tip L (Ca_L) contribuie la variatele semnale citosolice de calciu ce asigură controlul multor procese celulare fundamentale, cum ar fi contracţia, secreţia, neurotransmisia, expresia genică, etc. Influxul prin Ca_L reprezintă sursa majoră a semnalului contractil de Ca^{2+} în miocitele netede din artere de rezistenţă şi de conducere. Varietatea $Ca_v1.2$, prezentă în muşchiul neted vascular (MNV), are rol esenţial în contracţie şi în consecinţă în reglarea diametrului arterial, perfuziei tisulare şi a presiunii arteriale.

Estradiolul şi aldosteronul prezintă, în teritoriul vascular, pe langă efectele clasice, genomice, o serie de efecte rapide non-genomice. Aceste efecte ale estradiolului

(EST), mediate de receptori specifici şi parţial explicabile prin inhibiţia $Ca_v1.2$ din MNV, sunt ceva mai intens studiate datorită interesului pentru terapia hormonală de substituţie (1, 2). Deşi există o varietate a efectelor observate (3), în general acţiunea vasculară rapidă a ALD (mediată de receptorul clasic pentru mineralocorticoizi, MR) se traduce prin atenuarea efectului agenţilor vasoconstrictori, datorită activării NO-sintazei endoteliale (eNOS) precum şi prin potenţarea vasoconstricţiei în absenţa endoteliului, efecte comune cu cele ale cortizolului şi EST (4).

Am investigat importanţa $Ca_v1.2$ în efectele vasculare endotelio-independente ale EST şi ALD, precum şi implicarea unor mecanisme endotelio-dependente în efectele vasculare non-genomice ale acestor steroizi.

MATERIAL ŞI METODĂ

Am utilizat miografia izometrică a fragmentelor arteriale (~2 mm) din arcada mezenterică şi respectiv ramurile sale de ordin I de la şobolani Wistar masculi (~200 g). Preparatele au fost montate pe fire de oţel inoxidabil în migraful orizontal (JP Trading), tensionate treptat, până la o valoare a forţei pasive de 1 g şi echilibrate 90' (soluţie tampon HCO_3^-; 37° C; pH=7.2-7.4). Toate substanţele bioactive utilizate au fost din categoria pentru cercetare (Sigma, US) şi au fost administrate direct în baia de organ (volum util 5 ml) sub formă de volume mici de soluţii stoc; 50 µl; diluţie 1:100.

Prelucrarea datelor s-a efectuat off-line (Origin, Microcal Software, US). Pentru toate seriile experimentale rezultatele sunt exprimate ca medie a efectului respectiv (± ESM; n = 6). Diferenţele observate sunt testate din punct de vedere statistic prin testul Student pentru date grupate şi considerate semnificative pentru un coeficient de încredere mai mare de 99% ($p < 0,01$). Toate procedurile experimentale folosite sunt în concordanţă cu reglementările internaţionale în vigoare privind utilizarea animalelor în cercetarea ştiinţifică (Directiva 609 din 24 Noiembrie 1986, a Consiliului Comunităţii Europene).

REZULTATE ŞI DISCUŢII

Canalele de tip L din muşchiului neted vascular şi EST

EST relaxează arterele mezenterice de rezistenţă de la şobolan în absenţa endoteliului, independent de mecanismul precontracţiei (fig. 1), dar numai dacă acesta presupune influx de calciu prin Ca_L. Anterior am arătat că efectul relaxant al EST în aorta de şobolan în absenţa endoteliului nu se poate produce atunci când Ca_L sunt deja inhibate cu D600, un derivat de verapamil (5). Mai mult, în ramuri de ordin I ale arterei mezenterice, D600 inhibă efectul relaxant al EST în preparatul fără endoteliu funcţional (fig. 2).

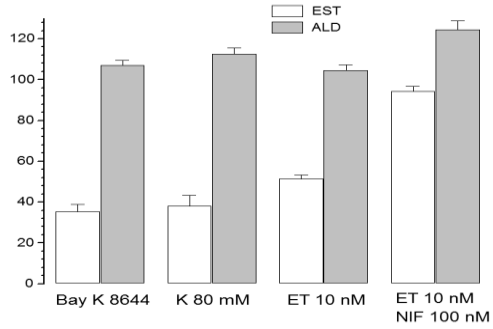

Fig. 1. Efectul relaxant al estradiolului (EST, 1µM) şi efectul contractant al aldosteronului (ALD, 1 µM) în inele din ramuri de ordin I ale arterei mezenterice de şobolan precontractate submaximal după cum urmează: prin activarea directă a $Ca_V1.2$ de către compusul Bay K 8644, prin depolarizare de către K^+ crescut extracelular (K 80 mM, prin activarea receptorilor ET_A de către endotelin (ET 10 nM) şi prin stimulare cu endotelin în condiţii de blocare completă a $Ca_V1.2$ de către nifedipină (NIF 100 nM).

Datele noastre completează observaţiile altor autori, care au arătat foarte recent că EST relaxează parţial arterele coronare porcine precontractate cu endotelin, iar nifedipina nu are efect suplimentar (6). EST inhibă contracţiile spontane şi pe cele induse de $CaCl_2$ şi KCl în duodenul de şoarece, prin activarea unor canale de K^+ şi inhibarea Ca_L (7). Cu toate acestea, EST are efect neuroprotector prin activarea Ca_L, creşterea calciului citosolic (Ca_c) ducând la activarea cascadei Src/ERK/CREB/Bcl-2 (8). Receptorul membranar de tip α pentru estrogeni (ERα) este capabil să asigure activarea Ca_L de către EST în celule pituitare, semnalul de Ca_c rezultat fiind implicat în stimularea de către EST a secreţiei de prolactină (9). Efectul inhibitor direct al EST asupra subtipului $Ca_V1.2$ de Ca_L a fost recent dovedit (10) prin studii de patch-clamp asupra acestor canale exprimate în celule de tip epitelial, din care lipsesc în mod normal.

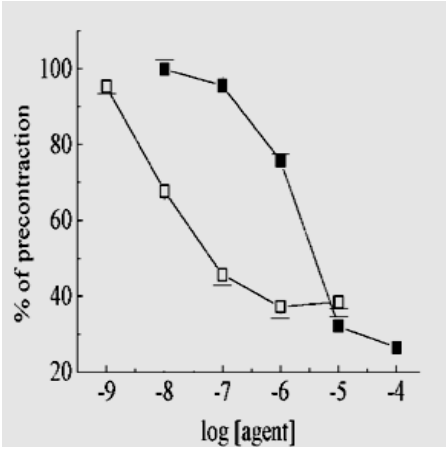

Fig. 2. Concentraţia corespunzătoare IC50 pentru D600 $5x10^{-7}$ M, induce o deplasare spre dreapta (pătrate goale) a curbei doză-relaxare pentru estradiol (pătrate pline) în artere mezenterice de rezistenţă în absenţa endoteliului.

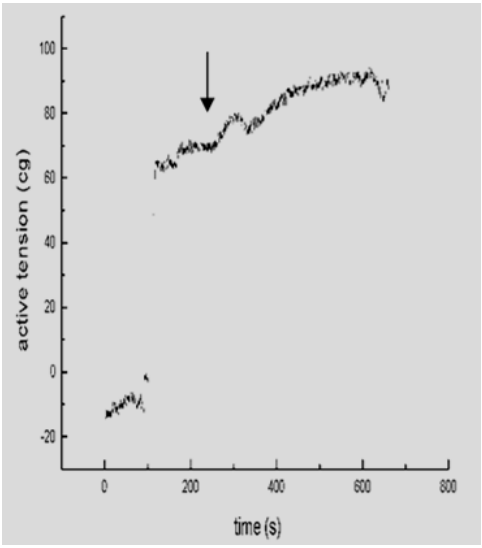

Fig. 3. Supracontracţia indusă de 1 μM aldosteron în ram din artera mezenterică precontractat cu fenilefrină 10 μM în absenţa endoteliului.

Canalele de tip L din muşchiului neted vascular şi ALD

ALD (10^{-9}-10^{-6} M) nu induce contracţie, nu influenţează contracţia indusă de K 40 mM sau fenilefrină 10^{-5} M, iar la concentraţii mari (10^{-6} M) determină o uşoară supracontracţie a ramurilor din artera mezenterică precontractate cu fenilefrină (fig. 3). În toate tipurile de vase studiate ALD reduce sensibilitatea contracţiei induse de fenilefrină faţă de acţiunea relaxantă a unui blocant Ca_L (metoxi-verapamil; D600, 10^{-7}-10^{-5} M).

Surprinzător, ALD are un efect asemănător, dar evident mai slab, chiar în cazul contracţiei induse de K^+ crescut, esenţialmente dependentă de Ca_L (5). S-a arătat de către alţi autori (11) că în artera mezenterică de şobolan ALD (10 nM) determină vasoconstricţie rapidă şi potenţează efectul vasoconstrictor al fenilefrinei, crescând rapid pH-ul intracelular şi Ca_c şi că activa-

rea MR în MNV de şobolan potenţează efectul contractil al fenilefrinei şi angiotensinei II, pe calea ERK1/2 (c-Jun, p38, Src) (12). În ramurile arterei mezenterice de la şobolan noi nu am observat un efect contractil indus de ALD şi nici efect potenţator asupra altor efecte contractile, spre deosebire de aortă, unde am observat potenţarea efectului fenilefrinei şi reducerea contracţiei induse de angiotensina II (5). Diferenţele menţionate pot fi explicate prin liniile diferite de animale folosite în aceste studii. Totuşi, supracontracţia indusă de ALD în artere mezenterice de rezistenţă precontractate cu fenilefrină (fig. 3) ar putea indica o potenţare a efectului fenilefrinei. Ulterior am identificat abilitatea ALD de a potenţa efectul contractil al endotelinului, dar numai când Ca_L sunt complet blocate (fig. 1).

Deşi nu sunt disponibile date de electrofiziologie în acest sens, reducerea sensibilităţii la D600 a efectului contractil indus de fenilefrină şi chiar de K^+ extracelular crescut (5), coroborată cu evidenţierea efectului potenţator al contracţiei indus de ALD (fig. 1), ne permite să speculăm privind posibilitatea ca ALD să deplaseze spre dreapta dependenţa de voltaj a Ca_L.

Implicarea unor mecanisme endotelio-dependente în efectele EST

În continuarea cercetărilor noastre asupra efectelor vasculare non-genomice ale EST (5), am examinat efectul rapid al EST asupra relaxării endotelio-dependente (RED) globale şi asupra componentei de tip EDHF, în cazul RED induse prin stimularea receptorilor muscarinici endoteliali în preparate vasculare precontractate prin stimularea alfa-1 adrenoceptorilor miocitari.

Am observant că EST facilitează RED, care devine mai puţin sensibilă la efectul inhibitor al blocării canalelor de potasiu dependente de calciu cu conductanţă mare (BK_{Ca}). În condiţiile în care raportul dintre componentele mediate de EDHF şi NO nu pare să fie modificat, motivul pentru care implicarea BK_{Ca} este diminuată şi mecanismul de potenţare a RED rămân să fie investigate; datele preliminare indică o eliberare crescută de oxid nitric (NO) şi o hiperpolarizare diminuată. Deşi mecanismele disponibile pentru activarea eNOS de către EST sunt relativ bine cunoscute, iar creşterea eliberării de NO este clar implicată în RED indusă de EST şi în potenţarea de către EST a RED indusă de alţi agenţi (13, 14) reducerea sensibilităţii RED la blocarea BK_{Ca} presupune o acţiune simultană a EST asupra MNV, cum ar fi inhibarea Ca_L.

Implicarea unor mecanisme endotelio-dependente în efectele ALD

Am examinat efectul rapid al ALD asupra RED globale şi asupra componentei de tip EDHF, în cazul RED induse prin stimularea receptorilor muscarinici endoteliali în preparate vasculare precontractate prin stimularea alfa-1 adrenoceptorilor miocitari. În arcada mezenterică de şobolan şi mai ales în ramurile sale de ordin I, aldosteronul exercită următoarele efecte în fragmente vasculare cu endoteliu intact: induce contracţie dacă este inhibată eNOS, inhibă în manieră NOS-dependentă contracţiile induse de fenilefrină şi de K^+ extracelular crescut şi potenţează RED indusă de carbachol, atât prin stimularea eNOS, cât şi prin amplificarea componentei EDHF evidenţiată în condiţiile inhibării eNOS (fig. 4). Efectele apar în general la concentraţii mai mari decât cele fiziologice şi nu sunt marcante ca în cazul teritoriului renal (15), ci relativ asemănătoare cu cele din sectorul brahial

uman (16). În mod evident aceste efecte se opun efectelor procontractile ale ALD pe care le-am discutat anterior şi este posibil ca disfuncţia endotelială (17) să încline balanţa în favoarea celor din urmă, în special în teritorii cheie, cum este cel renal.

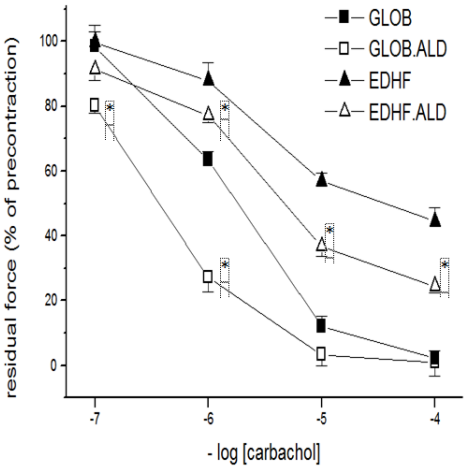

Fig. 4. Efectul relaxant endotelio-dependent indus de carbachol (pătrate pline) în artere mezenterice de rezistenţă de la şobolan este potenţat (*p<0.01) în prezenţă de 1 μM aldosteron (pătrate goale), cu participarea unei componente EDHF (triunghiuri pline) amplificate (*p<0.01) de aldosteron (triunghiuri goale).

CONCLUZII

Prin experimente de miografie izometrică a fragmentelor arteriale am identificat următoarele posibilităţi privind mecanismele care stau la baza efectelor vasculare non-genomice, rapide, ale EST şi ALD:

1. Ca_L sunt esenţiale pentru efectul relaxant al EST în aorta de şobolan şi sunt implicate în acest efect în artera mezenterică şi ramurile sale. Datele sugerează că EST, capabil să inhibe direct $Ca_v1.2$ transferate în celule renale embrionare (HEK), utilizează mai ales această cale pentru a induce RED .

2. ALD anulează participarea Ca_L la influxul de calciu activator al contracţiei în aorta de şobolan şi o reduce în artera mezenterică şi ramurile sale, posibil datorită unei deplasări spre dreapta a dependenţei de voltaj a Ca_L.

3. Chiar dacă nu produce RED în arterele mezenterice de la şobolan, EST este capabil să potenţeze RED indusă de carbachol, care devine mai puţin sensibilă la efectul inhibitor al blocării BK_{Ca}, iar ALD potenţează ambele mecanisme ale RED, mediate de NO, respectiv de EDHF, fapt ce contrabalansează efectele sale procontractile directe asupra MNV.

ABORDAREA LAPAROSCOPICĂ A TUMORILOR CHISTICE DE OVAR

R. Vieriu-Moţoc, E. Anton, N. Ioanid
Universitatea de Medicină şi Farmacie ”Gr. T. Popa” Iaşi
Facultatea de Medicină
Catedra IX Obstetrică Ginecologie

LAPAROSCOPIC APPROACH OF THE OVARIAN CYST TUMORS (Abstract): Given the continuous technical upgrade and increased surgical expertise, laparoscopy is replacing laparotomy in day-to-day gynecological surgical practice. Laparoscopic management offers many advantages for the patient: accurate diagnosis, minimal bleeding, reduced need for analgesia, less adhesion formation, fast recovery, better cosmetic results, shorter hospital stays (one day surgery in selected cases), and reduced costs for the patient and hospital. **Key words:** LAPAROSCOPY, OVARIAN CYST

În prezent tratamentul laparoscopic al tumorilor chistice de ovar a devenit o practică standard cu condiția unui diagnostic precis la momentul intervenției. Majoritatea tumorilor chistice ovariene sunt benigne (chisturi funcționale, dermoide sau endometriozice), tumorile maligne având o incidență de 7-13% în premenopauză şi 8-45% în postmenopauză (1), iar cele borderline de 9,2-16% (2). Riscul de a descoperi un cancer ovarian la momentul laparoscopiei este redus, 0.4% după Nezahat (3). Posibilitatea efectuării examenului anatomopatologic extemporaneu este obligatorie, deoarece o astfel de constatare obligă la conversie pentru stadializare şi tratament. Pentru a evita astfel de situații pacientele trebuie evaluate preoperator cât mai cuprinzător.

Evaluarea preoperatorie începe cu anamneza şi examenul clinic atent. Palparea unei formațiuni tumorale fixe, neregulate, însoțită de ascită este sugestivă pentru cancer. Examenul ecografic transvaginal este metoda principală de evaluare a maselor anexiale. Tumorile vor fi caracterizate din punct de vedere al mărimii, localizării, conturului, conținutului, loculației, grosimii septurilor, prezenței vegetațiilor şi a lichidului liber intraperitoneal. Predictibilitatea ultrasonografiei endovaginale este de aproximativ 96% pentru tumorile benigne (4). Utilizarea ecografiei Doppler transvaginale poate facilita diferențierea tumorilor benigne de cele maligne, acestea fiind caracterizate de impedanță scăzută a fluxului sanguin (IP<1). Dozarea preoperatorie a markerilor tumorali, în mod particular a CA125, este utilă în special la pacientele aflate în postmenopauză. Valori peste 65 UI/ml au o specificitate de 97% cu o sensibilitate de 78% pentru tumorile maligne (5).

Dacă la finalul evaluării suspiciunea de malignitate este ridicată pacienta va fi evaluată în continuare prin examen CT sau RMN, urmând a fi supusă laparotomiei de stadializare. În caz contrar se va planifica intervenția laparoscopică (6).

Pregătirea preoperatorie

Pacienta va fi consiliată despre posibilele

descoperiri intraoperatorii, despre tehnica chirurgicală, despre riscul de conversie şi se va obţine consimţământul informat. Se va pregăti mecanic intestinul, se va monta o sondă Foley şi un manipulator uterin după pregătire vaginală prealabilă. Se va dezinfecta întreaga suprafaţă a abdomenului datorită riscului de conversie (7).

Tehnica chirurgicală

Intervenţiile se vor desfăşura sub anestezie generală. Instrumentarul laparoscopic constă in 1 trocar de 12 mm, 2-3 trocare de 5 mm, telescop de 10 mm, cu unghi de vizualizare de 0°, ac Veress, canula de irigaţie-aspiraţie, electrocauter bipolar sau monopolar, pense, foarfeci, ac laparoscopic pentru aspirarea conţinutului chistului. Se începe cu o incizie subombilicală de 2-3 mm necesară introducerii acului Veress. În cazul abdomenului cicatriceal poate fi necesară utilizarea unei tehnici de laparoscopie deschisă. După verificarea localizării intraperitoneale a acului Veress şi realizarea pneumoperitoneului se introduce subombilical trocarul de 12 mm. Trocarele de 5 mm vor fi introduse, unul la 3-4 cm suprasimfizar, iar celelalte două la nivelul crestelor iliace, extern de muşchii drepţi abdominali şi vasele epigastrice inferioare. Inspecţia cavităţii peritoneale şi recoltarea de lichid peritoneal pentru examen citologic este urmată de intervenţia propriu-zisă. În cazul tumorilor chistice de ovar 3 tehnici chirurgicale sunt utilizate în prezent: chistectomia, ovarectomia şi anexectomia (8).

Chistectomia

Indicaţii: vârstă sub 45 ani, chist benign.

Procedeul constă în îndepărtarea în totalitate a peretelui chistului în scopul evitării recidivei şi realizării unui examen anatomopatologic cât mai complet (9). Chistectomia ideală presupune îndepărtarea chistului intact. Dacă acest lucru nu este posibil se recurge la puncţia chistului, aspirarea conţinutului şi excizia peretelui. Ovarul este expus complet prin tracţiunea ligamentului utero-ovarian cu o pensă atraumatică pentru a putea aprecia dimensiunea corectă a chistului (10). Cu ajutorul foarfecii se efectuează o incizie la nivelul cortexului ovarian la limita dintre chist şi ţesutul ovarian normal. Incizia serveşte creării unui plan de clivaj între capsula ovarului şi peretele chistului. Ea trebuie să fie paralelă cu axul lung al ovarului şi nu trebuie să producă ruptura chistului. Utilizând hidrodisecţia (soluţie Ringer, vasopresină diluată) sau disecţia boantă, se avansează treptat in planul de clivaj pentru enuclearea chistului. Metoda este preferată atunci când există un chist dermoid sau unul mucinos, deoarece contaminarea peritoneului cu astfel de conţinut poate fi însoţită de peritonită granulomatoasă, în primul caz, sau apariţia pseudomixomei peritonei, în cel de al doilea caz (8).

Îndepărtarea intactă a chisturilor mai mari de 12 cm se poate dovedi dificilă pe cale laparoscopică. În această situaţie este necesară o altă abordare care constă în puncţionarea iniţială şi aspirarea conţinutului. Acest lucru poate fi realizat prin intermediul unui ac laparoscopic de 18 gauge introdus prin canula de aspiraţie-irigaţie sau cu ajutorul unui trocar de 5 mm. Trocarul este introdus în interiorul chistului împreună cu teaca sa, iar după puncţie trocarul este extras şi în teacă este introdusă canula de aspiraţie (6). Conţinutul este trimis pentru examen citologic. După lavajul suprafeţei interne a chistului se practică chistoscopia prin introducerea laparoscopului în interiorul chistului. Dacă se constată prezenţa vegetaţiilor intrachistice, acestea vor fi biopsiate şi examinate anatomopatologic extemporaneu. Următorul timp operator constă în evacuarea peretelui chistului prin separarea acestuia de cortexul

ovarian. Cele două structuri sunt prinse cu pense atraumatice şi prin tracțiune divergentă se realizează separarea lor. Pot exista dificultăți în identificarea peretelui chistic. În această situație marginile orificiului de puncție vor fi lărgite cu foarfeca rezultând margini clare uşor de identificat. Dacă prin aceste manevre cămaşa chistului nu poate fi îndepărtată ea va fi apucată şi tracționată din interior concomitent efectuându-se contratracțiune pe ovar (6).

După îndepărtarea chistului, ovarul restant va fi irigat abundent cu ser fiziologic sau soluție Ringer. Hemostaza se realizează frecvent spontan, în caz contrar va fi utilizat electrocauterul bipolar. Dacă marginile capsulei ovariene se suprapun, ovarul este lăsat să se vindece singur. Dacă nu se suprapun pot fi necesare câteva suturi cu fir subțire monofilament, rezorbabil.

Ovarectomia este indicată în cazul chisturilor ovariene recidivante, atunci când chistul a distrus în totalitate parenchimul ovarian, sau în cazul unor mase ovariene persistente în postmenopauză.

Principiile ovarectomiei clasice se aplică şi în cazul ovarectomiei laparoscopice. Inițial este importantă identificarea traiectului ureterelor, iar apoi identificarea şi izolarea vaselor ovariene la nivelul ligamentului lombo-ovarian (11). Acest lucru se realizează prin incizia peritoneului ligamentului larg între ligamentul rotund şi trompa uterină. Fiind un spațiu avascular, accesul între foițele anterioară şi posterioară a ligamentului larg este facilă, iar scheletizarea ligamentului lombo-ovarian se realizează cu uşurință. Eliberarea ovarului de pediculii săi poate fi realizată prin mai multe metode. Fie se cauterizează ligamentul lombo-ovarian, scheletizat în prealabil şi apoi ligamentul utero-ovarian, fie se utilizează ligaturile preformate (Endoloop) sau clipurile metalice.

Anexectomia se efectuează pacientelor cu leziuni benigne care nu doresc o nouă sarcină.

Tehnica este similară ovarectomiei cu mențiunea că este necesară disecția bazei anexei la nivelul ligamentului larg şi coagularea extremității proximale a trompei (8).

Țesuturile vor fi extrase din abdomen utilizând unul din următoarele procedee:

1. Endobag – mici saci din material plastic introduşi în cavitatea peritoneală prin intermediul trocarului de 10 mm. Țesutul este introdus in sac, acesta este tensionat şi după îndepărtarea tecii trocarului, sacul este extras prin incizia de la nivelul peretelui abdominal. Folosirea endobag-ului necesită aspirarea conținutului tumorilor chistice sau morselarea celor solide in interiorul sacului. Nu este recomandată evacuarea intactă a tumorilor deoarece există riscul de rupere a sacului şi de contaminare a cavității peritoneale şi a peretelui abdominal.

2. Colpotomie posterioară – utilizată în cazul tumorilor solide de dimensiuni mai mari. Colpotomia va fi închisă pe cale vaginală sau laparoscopică. Studiile au arătat că acest procedeu nu este însoțit de aderențe postoperatorii semnificative (12).

3. Extragerea prin peretele abdominal. Unul din trocarele de 5 mm este înlocuit cu cel de 10 mm, iar piesa operatorie este extrasă odată cu teaca trocarului.

Este importantă evitarea contaminării cavității peritoneale sau a peretelui abdominal cu țesuturi tumorale – au fost raportate metastaze la nivelul peretelui în caz de tumoră malignă (13, 14). Dacă acest lucru se întâmplă, este necesară spălarea peritoneului cu cantități mari de soluție Ringer.

Complicații

- ruptura intraperitoneală a chistului – semnificativă în cazul chistului mucinos, dermoid sau endometriozic. Se va spăla

abundent peritoneul până la clarificarea lichidului de lavaj.

• hemoragia – dacă nu poate fi controlată prin electrocauterizare poate duce la conversia intervenţiei.

• insuficienţă ovariană – în caz de coagulare în exces a parenchimului ovarian.

• leziuni ale ureterului – se vor rezolva prin conversie.

• recurenţa – în caz de excizie incompletă.

• formarea de aderenţe postoperatorii – mai frecventă după chisturile endometriozice (15). Se vor evita suturile tranşei ovariene. La sfârşitul intervenţiei se vor lăsa în pelvis aproximativ 1000 ml soluţie Ringer sau se vor folosi dispozitive care impiedică apariţia aderenţelor (Interceed).

CONCLUZII

1. Managmentul laparoscopic al tumorilor ovariene chistice este în continuă creştere datorită avantajelor în ceea ce priveşte morbiditatea, recuperarea şi implicaţiile economice comparativ cu chirurgia clasică.

2. Pacientele trebuie atent selectate prin evaluare preoperatorie cât mai completă.

3. Examenul anatomopatologic extemporaneu trebuie să poată fi efectuat imediat dacă se tentează evacuarea tumorii prin laparoscopie.

4. Dacă este detectat un proces malign este indicată conversia la laparotomie de stadializare.

SYSTEMATIC REVIEW REGARDING PSYCHOLOGICAL AND PHYSIOLOGICAL PROCESS ASPECTS ABOUT THE METHODS OF INDUCING LABOR (Abstract**): Aim** review article aims to synthesize the mechanisms involved in triggering labor, focusing on the cervical phenomena resulting in maturation, cervical dilation and fetal expulsion. Furthermore, this article highlights the ways in which labor may be induced. **Material and methods:** The data collected by accessing *Medline; Medscape; PubMed* and *ISI Web of Knowledge* using the following keywords: labor induction, oxytocin, cervix ripening, prostaglandins, uterine contraction, amniotomy, membrane stripping, misoprostol, Foley catheter. Review articles, original articles, as well as, case reports were taken into consideration when the search was performed. We identified more than 1,000 abstracts and reviewed over 150 full text articles using the keywords listed above. We preferentially included high quality systematic reviews or large randomized trials. **Results:** After reviewing the literature we included 28 full text articles in our analysis. A series of factors should be taken into consideration by the obstetrician before considering inducing labor. There are studies that compare the use of oxytocin versus prostaglandins for labor induction and the results are in favor of prostaglandins with a lower rate of number of pregnancies completed by segmental transversal cesarean. However, administration of oxytocin may increase the risk of termination of pregnancy through segmental transversal cesareans. In contrast to, oxytocin and prostaglandins, the mechanical methods of inducing labor may increase the risk of both maternal and neonatal infectious. **Conclusions:** The decision to trigger labor requires the obstetrician to carefully analyze the timing of induction of birth and the risks and benefits, considering, for each patient, the most effective method of triggering. Thus, we emphasize on the necessity of developing protocols to guide obstetricians, since there is no consensus on the doses that should be administered. The cost-effectiveness of the treatment should be considered. **Keywords**: PSYCHOLOGICAL, PHYSIOLOGICAL, BIRTH, TRIGGER, INDUCING LABOR, OXYTOCIN, CERVIX RIPENING.

Birth is an ensemble of phenomena culminating with the expulsion of the fetus and its annexes from the maternal body. Myometrial and cervical cell interactions

are decisive in triggering labor. There are certain situations where expectation is not a solution, thus labor must be induced. This review article aims to synthesize the mechanisms involved in triggering labor, focusing on the cervical phenomena resulting in maturation, cervical dilation and fetal expulsion. Furthermore, this article highlights some of the ways in which labor may be induced. Existing literature suggests that labor should be triggered under certain conditions, calculating very carefully the risks and benefits. The goal of the induced labor is to give birth, in a safely manner, to a healthy newborn (1).

MATERIAL AND METHODS

Throughout its evolution, consciously or mimetic, everyone chooses a model to build his labor (2, 3). We choose for this study the data collected by accessing MEDLINE; MEDSCAPE; PUBMED and ISI WEB OF KNOWLEDGE using the following keywords: labor induction, oxytocin, cervix ripening, prostaglandins, uterine contraction, amniotomy, membrane stripping, misoprostol, Foley catheter. Review articles, original articles, as well as, case reports were taken into consideration when the search was performed. We identified more than 1,000 abstracts and reviewed over 150 full text articles using the keywords listed above. We preferentially included high quality systematic reviews or large randomized trials.

BACKGROUND

The physiological process of birth occurs on average after 280 days (40 weeks or 10 obstetric months of 28 days each) from fertilization, during which the fetus becomes viable in extrauterine conditions, and is the result of completing a fetal-placental development process, which induces numerous endocrine and neurohormonal regulation systems in the maternal body (4). The mechanisms involved in triggering labor are multiple, varied and are regulated by maternal, fetal and placental factors (the concept of maternal-feto-placental unity), which may be classified as initiation factors such as oxytocin, prostaglandins and gap junctions, and complementary factors (adjuvants) (Humphrey *et al.*, 2009).

The uterine muscle is intrinsic inactive, and according to Caldeyro Barcia's theory, the most important factor in birth initiation is oxytocin (5), a hormone secreted in the posterior pituitary gland that enables the sensitization of the myometrial fibers allowing the propagation of the wave contraction between adjacent muscle fibers, and further on the transmission of the contraction in the myometrium (6).

Physiological mechanism of labor

During pregnancy, the fluctuations of circulating oxytocin levels may not correspond to changes in uterine activity, however, the onset of birth, because of prostaglandins action and lower uterine distention in the inferior part (Ferguson reflex), the blood level of this hormone is significantly increased (7).

A fundamental factor in labor, prostaglandins (PG) influence both the cervical maturation (PG E2) as well as the myometrial contractility. In contrast to PG F2α and PG E2, which stimulate uterine contraction, PG I2 induces relaxing action on the musculature in the vascular wall and myometrium (8). The main sources of prostaglandin production are in the fetal membranes, PG E2 at the level of the chorion and amnius, deciduous (PG E2 and PG

F2α) and in the myometrium (PG I2).

As the birth term approaches, the amniotic and deciduous levels of prostaglandin grow sensitively until a certain time when more intense, coordinated, active-propagated uterine contractions are induced, either directly by the action of prostaglandins or indirectly after the myometrium has been sensitized by its own oxytocin (9) or, perhaps, of by oxytocin of fetal origin.

The interaction between OXT and PG determines the stimulation of the myometrial contractility. The latter mentioned potentiate the oxytocin-induced uterine contractions, leading to cervical wiping and the establishment of uterine activity (10). In order for the labor to progress to the active phase, the deciduous prostaglandin levels must increase.

The gap-junctions, also called nexus, represent a type of intercellular junctions, virtually absent during gestation, which allow the electrical, ionic and molecular coupling between two myocytes, favoring their coordination and the propagation of the uterine contraction at the level of the entire myometrium (11).

Unlike the His beam, responsible for the synchronization of the cord contractions, no such structures have been identified in the uterus. The period preceding labor is characterized by an increase in the number of junctions, as well as an amplification of their length. Meanwhile, JP is also involved in the dilation of the cervix (12).

Methods of inducing labor

Among the adjuvant factors of labor initiation, it is worth mentioning the steroid hormones, immunological and mechanical factors and prolactin, which through its antagonistic action on the uterus compared to relaxin, can stimulate uterine contractility (the urotropine/uterotonine complex signal theory).

Steroid hormones (estrogen and progesterone) play a fundamental role in the labor mechanism (13), having on one hand a modulating action on PG and oxytocin and, on the other hand, regulating the membrane potential of the myometrial cells and actin-myosin interaction.

Urotropines are the substances that determine the synthesis of the functional elements that prepare the myometrium for labor: steroid hormones, growth factors (TGFβ, activin A), PGF2α, PTH-rP (14). Just it is clear that muscle involvement in chronic inflammatory disease represents a well-recognized manifestation, multiple factors contributing to the development of muscle disease: pro-inflammatory cytokines such as TNF-α and IL-1 acting in muscle environment with subsequent damage of muscle and abnormal muscle metabolism (15, 16, 17).

Uterotonins are substances that cause the contraction of smooth uterine muscle fibers by increasing intracytoplasmic calcium concentration: oxytocin, endothelin-1 (18).

Labor induction is an intervention method that aims to initiate contractions before their spontaneous triggering (19). The decision to triggering labor is influenced by many factors, which should be should consider by the obstetrician: gestational age, fetal pulmonary maturity, maternal and fetal state severity, and predictive maternal factors for triggering success, such as the Bishop score or parity (20).

According to the ACOG Committee on Practice Bulletins - Obstetrics in 2009 (1), birth is induced in 1 of 5 pregnancies due to maternal factors (preeclampsia, re-

nal/cardiac), fetal causes (intrauterine growth restriction with Doppler indices on fetal mean cerebral artery and on the umbilical artery), or maternal-fetal causes such as uncontrolled gestational diabetes, premature spontaneous rupture of membranes, or post-mature pregnancies (when the pregnancy exceeds 40s + 6z, up to 41s + 6z) (21).

Notwithstanding, these pathologies are associated with increased maternal and fetal morbidity and mortality. In cases where natural birth is contraindicated, or if the physician is in the presence of an obstetric emergency (e.g. hemorrhage in central placenta previa or fetal acute distress), cesarean operation must be performed. The contraindications of induced birth may be absolute or relative.

Some of the absolute contraindications are: cephalo-pelvic disproportion (tight birth canal/macrosomic fetus), dystocic pelvis, central placenta previa, transverse fetal presentation, umbilical cord prolapses, obstructive mass at the level of the female genital tract, invasive cervical cancer. The relative contraindication is: previous c-sectioned uterus, bridge presentation, multiple pregnancies, maternal cardiopathic, low biophysical score, previous myomectomy, neonatal trauma at previous birth.

Over time, the role of the cervix in contending the product of conception, its implication in labor and parturition were considered key elements for the successful completion of a pregnancy. Cervical maturation refers to changes in the cervix that are required for triggering labor, such as cervical dilation and vaginal expulsion of the fetus.

The uterine cervix is composed of smooth muscle fibers (10%) and connective tissue (90%), in which the fibroblasts ensure the synthesis of most of extracellular matrix consisting of collagen (type I and type III) and representing 80% of the proteins cervical: glycoproteins and proteoglycans. Collagen fibers are closely linked and solidarized by glycoproteins and proteoglycans.

Collagen fibers are closely linked and solidarized by glycoproteins and proteoglycans. Proteoglycans are macromolecules consisting of a protein base, branched into polyacid structures, glycosaminoglycans (GAGs). Hyaluronic acid and hydrogenated proteoglycan represent 15% of GAG and play a major role in tissue hydration. The cervical maturation phenomena take place in the last trimester of gestation. Clinically, these modifications may be described as a rambling of the cervix and diminished resistance to dilation, because of collagen network total organization, which is responsible for changes in the mechanical properties of the cervix (22).

During pregnancy, several morpho-functional changes occur in the cervix, leading to a cellular infiltration (23). Fibroblasts become more numerous and mature. They represent a phagocytosis activity through local histiocytes as well as other cells. Additionally, there are other cellular infiltrations (polynuclear, mast cells) present. Ultrastructural studies demonstrated that the complete modification of the collagen network, which spreads, becomes hydrated.

At term, the amount of intermolecular collagen binding decreases, subsequently, the collagen becomes more easily dispersible and more hydrophilic (24). The collagenolytic capacity of the cervix increases as the birth approaches, favoring collagen destruction and cervical rupture. Thus, there is a decrease in collagen concentra-

tion and a destruction of the tropocollagen.

With the onset of labor, under the influence of uterine contractions that create increased intrauterine pressure, the uterine cervix relieves progressively, the cervical canal dilates, and the gelatinous plug is removed from the cervix area. Because of the gradual opening of the canal, the canal takes the form of a funnel that is embedded in the lower segment. During the opening, the cervical canal is shortened, completely wiped out, leaving only the external opening closed. The edges of the neck are thin, elastic, and the external opening begin to open.

With each contraction, the degree of opening of the external orifice increases until it is fully opened. Assessment of cervical condition is the most important factor in the decision of triggering labor. In the long run, cervical status is quantified using the Bishop score (25), which involves examining five factors: cervical dilation (cm), neck length/wiping, consistency, position, position of the fetal pole (ratio of the lower pole of the fetal head to interspines ischia line). In the past, at a score of ≥ 6, triggering of labor was achieved by performing amniotomy (26).

Amniotomy increases the synthesis and local elaboration of prostaglandins, which, in turn, contributes at triggering birth. Currently, due to complications such as umbilical cord prolapses and/or compression, increased risk for maternal/neonatal infections, fetal heart rate deceleration, early membrane rupture is no longer recommended to be used as first intended technique for labor induction. In such cases, intravenous infusion of oxytocin is administered while the fetal heart beats are closely monitored.

Studies have shown that induction of labor by oxytocin decreases the number of days of hospitalization and the number of newborns requiring neonatal care in intensive care units but increases the risk of termination of pregnancy through segmental transversal cesareans (27). Nevertheless, the complications of oxytocin administration may be:

1. increased uterine tone - In addition, there are many contradictions in this area of research regarding the levels of some oxidative stress markers, as they have been shown to either increase, decrease or remain unchanged after labor. That labor-induced oxidative stress might be prevented by some antioxidant interventions, there is still insufficient knowledge about the possible protective effects of antioxidants against oxidative damage (28).
2. impaired fetal heart rhythm,
3. uterine rupture on the uterine scar,
4. when the total oxytocin dose exceeds 60 IU, it may cause a psychomotor retardation in 3-5-year-old children.

Parity, cervical dilation and gestational age are predictive factors for a favorable response to oxytocin administration.

A Bishop score less than 6 involves a cervix that is appropriate for triggering the birth. In such cases, pharmacological or mechanical methods for cervical maturation may be used.

Pharmacological methods of inducing labor

Prostaglandins (PGE1 and PGE2) are the most commonly used cervical maturation drugs. The synthetic analogue of PGE1 is Misoprostol, which is found under the form of tablets and is a gastric cytoprotector used predominantly in the treatment and prophylaxis of gastric ulcer. At the level of the cervix, it increases the concentration of prostaglandins, increases the activity of

collagenase, which in turn increases the concentration of elastase, glycosaminoglycans, dermatan sulfate and hyaluronic acid, resulting in rambling and dilation of the cervix.

Misoprostol may be administered intravaginally (25 μg/6 hrs.) (either in the vaginal posterior fornix or intracervical) or orally (25 μg/2 hrs.), and studies have shown that Misoprostol administered orally has superior benefits as compared to intravaginally administration (29). Furthermore, a meta-analysis conducted by Alfirevic (30), revealed that the low dose administration of Misoprostol may be more cost-effective than other combinations used for the induction of labor.

The synthetic analogue of PGE2 is called Dinoprostone and is marketed in various forms: gel, suppositories, tablets, intravaginal dose-dispensing device while may be administered intracervical or intravaginal. There are studies that compare the use of oxytocin versus prostaglandins for labor induction and the results are in favor of prostaglandins with a lower rate of number of pregnancies completed by segmental transversal cesarean (31).

Mechanical methods of inducing labor

The mechanical methods used to induce labor have the same principle of action, local pressure, which induces the local secretion of endogenous prostaglandins. For this purpose, are used Foley catheter with / without extra amniotic saline infusion and osmotic dilators (32).

The main principle of action of membrane stripping is like mechanical dilation of the cervix. By manual detachment of membranes, a chain of successive reactions is triggered by activation of phospholipase A2 and prostaglandin F2α, leading to cervical maturation (33). This method of triggering labor is not recommended for patients in which was identified a pathogen in the culture of vaginal secretions prelevated previously. In these cases, labor induction will be attempted only after the patient is completely treated with antibiotic and the culture of the vaginal secretion will present only the saprophytic flora. Recent studies have shown that the use of mechanical methods increases the risk of endometrial infections and neonatal sepsis, hemorrhages, premature rupture of the amniotic sac or normal insertion of the placenta.

Artificial triggering of labor may be accompanied by complications such as hyperstimulation, defined as uterine contraction that lasts >60 seconds, or more than 4 contractions in 10 minutes, tachysystole (6 or more uterine contractions in 10 minutes), hypersistolia (a contraction lasting at least 2 minutes), uterine rupture, amniotic embolism, postpartum uterine hypotonia, and fetal heart rate deceleration (34).

CONCLUSIONS

The purpose of meta-analysis is to help clinicians to make the appropriate decision based on solid information. Worldwide, the rate of labor induction has increased constantly. Although many methods for inducing labor have been tested, prostaglandins remain the method of choice in many hospitals and clinics, misoprostol tablets being administered either orally or vaginally. However, in terms of cesarean section risk, the oral administration is safer.

The decision to trigger labor requires the obstetrician (the results are important for obstetrics physicians to explain the level of satisfaction related to their personality) (35), which must carefully analyze the timing of induction of birth, the risks

and benefits, considering, for each patient, the most effective method of triggering (Leventhal's Self-Regulatory Model-SRM) (36, 37).

Thus, we emphasize on the necessity of developing protocols to guide obstetricians, since there is no consensus on the doses that should be administered. The cost-effectiveness of the treatment should be considered.

2. Clinica a V-a Pediatrie-Gastroenterologie

TOTAL PARATHYROIDECTOMY WITHOUT AUTOTRANSPLANTATION IN THE MANAGEMENT OF „REFRACTORY" RENAL HYPERPARATHYROIDISM (Abstract)**.** The optimal surgical treatment in patients with refractory renal hyperparathy-roidism (RHP) on hemodialysis for end stage renal disease is still a point of controversy. The high percentage of recurrences after standard surgical procedures i.e. subtotal parathyroidec-tomy (SPTx) and total parathyroidectomy with autotransplantation (TPTx + At) reactualised the practice of total parathyroidectomy (TPTx). **Material and method :** Fortythree patients with RHP underwent surgery between 1994-2009. There were 24 SPTx and 6 TPTx + At, both procedures determining 20,7 % (6 cases) recurren-ces so in the last five years TPTx was performed in a series of 13 cases (7 men and 6 women, with median age 43,6 years ; range 22 – 65 years and median dialysis time before PTx 8,2 years ; range 3 -12 years. Parameters studies included demographics, preoperative and follow-up laboratory tests, surgical techniques, pathology results and postoperative immediate and medium term results. **Results :** Main indications for PTx were severe bone disease, soft tissue calciphycations, neuro muscular phenomena, grossly elevated iPTH and sometimes hypercalcemia. TPTx was done in 12 patients, the 13th one suffering a completion PTx one year after outward exeresis of only two glands. Postoperatively the majority of symptoms markedly improved and the values of calcaemia, phosphatemia and alkaline phosphatasis normalised together with low or no measu-rable level of iPTH. One patient required a re-exploration for a cervical hematoma but no one presented permanent hypocalcemia or recurrent hyperparathyroidism.Pathology revealed nodu-lar hyperplasia in all the cases, a parathyroid carcinoma but also an incidental thyroid papillary microcarcinoma in a complementary thyroidectomy. **Conclusions :** TPTx alone proves to be an equally safe and successful as another techniques currently used in management of RHP eliminating the hyperparathyroid status but being supe-rior with regard to aparition of recurrences. The procedure is indicated especially in cases with aggressive, refractory forms of RHP without the prospect of renal transplantation. **Key words** : PARATHYROIDECTOMY, AUTOTRANSPLANTATION, RENAL HYPERPARATHYROIDISM

Hiperparatiroidismul renal (secundar/terţiar) – HPR condiţie care virtual interesează totalitatea bolnavilor uremici supuşi hemodializei cronice este redefinit în prezent într-un concept integrativ sub acronimul CKD-MBD – boala metabolică osoasă din insuficienţa renală cronică, caracterizat prin prezenţa izolată sau combinată a trei componente :

- anomalii ale metabolismului calciului, fosfaţilor, PTH şi vitaminei D datorită

hiperfuncţiei paratiroidiene ;
- anomalii ale turnoverului, mineralizării, volumului, creşterii sau rezistenţei osoase (mai vechea osteodistrofie osoasă) ;
- calcificări vasculare, cardiace şi ale ţesuturilor moi şi calcifilaxie, toate realizând în timp o morbi-mortalitate crescută.

Creşterea constantă a numărului bolnavilor cu insuficienţă renală cronică implicit a celor cu HPR a condus la dezvoltarea eficientă a programelor de hemodializă, completată de administrarea de vitamine active din grupul D sau omologi, bifosfonaţi şi preparate calcimimetice care în absenţa tratamentului ideal – transplantul renal – controlează eficient pe perioade îndelungate, evoluţia clinică şi biologică a majorităţii acestor bolnavi.

Rămâne însă un procentaj de 15% dintre cazuri de aşa zis HPR „refractar" (care poate atinge chiar 38% după 20 ani de hemodializă) în care transformarea ireversibilă a hiperplaziei difuze în hiperplazie nodulară, alături de evoluţia severă, invalidantă a sindromului clinic şi a constantelor biologice nu mai poate fi influenţată de tratamentul medical şi este indicată o soluţie chirurgicală.

Procedurile operatorii reducţionale iniţiate în urmă cu jumătate de secol au recurs preferenţial fie la paratiroidectomia subtotală - PTxsT - fie la paratiroidectomia totală cu autotransplant glandular în diverse zone anatomice – PTxT+At -, considerate în mod tradiţional tehnicile standard pentru tratamentul acestor condiţii, au fost marcate negativ în timp de procentajul ridicat de recidive – 5-80%. Propusă în 1967 de către Ogg paratiroidectomia totală – PTxT – a fost rapid abandonată datorită riscului de osteopatie adinamică şi hipoparatiroidism permanent este reconsiderată în ultimele două decenii de numeroşi specialişti datorită anulării acestui risc şi rezultatelor favorabile imediate şi pe termen mediu comparabile cu celelalte două metode.

În experienţa noastră – însumând 43 observaţii de HPR operate între 1994-2009 – am practicat toate cele trei tehnici. Iniţial şi prioritar am preferat PTxsT – 24 cazuri şi PTxT+At – 6 cazuri, dupa ambele proceduri înregistrând 20,7% (n – 6) recidive, astfel că în ultimii cinci ani ne-am orientat pentru anumite cazuri catre PTxT, executată în 13 cazuri.

PACIENŢI ŞI METODĂ

Seria noastra cuprinde 13 observaţii de HPR „refractar" – 7 bărbaţi şi 6 femei, cu vârste cuprinse între 22 – 65 (medie 43,5) ani, aflaţi de 3 – 12 (medie 8,2) ani în regim de hemodializă.

În 12 cazuri a fost vorba de intervenţii primare, într-un singur caz reexplorarea chirurgicală fiind practicată unui tânăr de 22 ani căruia în cadrul unei exereze „ţintite" efectuate în alt serviciu i-au fost identificate şi îndepărtate doar paratiroidele superioare (!).

În etiologia HPR am notat glomerulo-(pielo)nefrita cronică – 9 cazuri, urolitiaza – 2 cazuri, rinichi polichistic şi nefroangioscleroză în câte un caz. Doi bolnavi prezentau în antecedente şi un transplant renal eşuat.

Criteriile de includere în varietatea „refractară" a HPR au cuprins evoluţia prelungită a afecţiunii cât şi a hemodializei, severitatea deosebită a unor manifestări clinice şi complicaţiilor acestora, modificările semnificative ale unor date de laborator dar mai ales lipsa de răspuns (mai mult decât de complianţă) la măsurile medicale şi mai ales a oricarei perspective de efectuare a unui transplant renal.

Astfel sindromul clinic, componenta implicită a indicaţiei chirurgicale a cuprins (tab. I).

Valorile principalelor constante biologice şi a produsului Ca/P au fost de asemenea semnificativ modificate (tab. II).

Ultrasonografia practicată de rutină, respectiv scintigrafia cu sestamibi sau tetrofosmin accesibila sporadic nu au fost

TABELUL I

Frecvenţa principalelor manifestări clinice în HPR „refractar"

Manifestări clinice	Nr. cazuri	%
osteoartralgii, osteoporoza, fracturi	13	100
prurit rebel	12	92
insomnie, sindrom astenocomportamental	10	78
(mi)astenie, anemie, hipoproteinemie, malnutriţie	10	78
HTA, cardiopatie ischemică,miocardoscleroză	8	61
calcifilaxie, calcificări ectopice, ochi roşii "uremici"	6	46
manifestări dispeptice	4	30
urolitiază, colici renale	2	15

TABELUL II

Valorile medii ale principalelor teste de laborator în HPR „refractar"

iPTH	1620 + 320 ng/l
Calciu seric	8,70 + 1,00 mg/dl
Calciu ionic	4,45 + 0,38 mg/dl
PO4 seric	4,60 + 0,55 mg/dl
Fosfataza alcalină	280 + 38 ui/l
Hb	11,3 + 2,3 mg/dl
Proteine	49,5 + 0,9 g/dl
Uree	140 + 4o mg/dl
Creatinina	1,8 + 0,3 mg/dl

relevante pentru diagnosticul observaţiilor noastre, utilitatea lor rezumându-se la identificarea a 1 – 3 glande „mai mari" – peste 8 – 10 mm O - dar mai ales a leziunilor tiroidiene concomitente. Prezenţa a cel puţin unei paratiroide cu aceste dimensiuni s-a adăugat însă anamnezei, sindromului clinic sever şi valorilor exagerate ale iPTH – toate consfinţind eşecul tratamentului medical - şi mai ales considerentelor sociale cu lipsa perspectivei unui eventual transplant renal, toate constituind argumentele care au formulat indicaţia tratamentului chirurgical în aceste cazuri.

Constatările intraoperatorii au fost însă elementul precumpănitor care au decis opţiunea pentru practicarea acestui tip de exereză glandulară. Astfel, cel puţin două, dacă nu toate paratiroidele au apărut globuloase, pseudoadenomatoase dar mai ales mult mărite de volum depăşind copios dimensiunile obişnuite fiind astfel mult mai uşor de identificat intraoperator, biopsia extemporanee căpătând un caracter formal. Au fost excizate în total 51 glande cu dimensiuni între 0,8 – 2,8 cm (trei paratiroide din care una supranumerară situată retrosternal la bolnavul cu reintervenţie). Masa totală a parenchimului glandular extirpat a depăşit în unele situaţii de 10 ori greutatea normală atingând chiar 1500 mg.

În toate aceste cazuri prin dimensiuni şi conformaţie, aspectul macroscopic a obligat practic la îndepărtarea succesiva a tuturor celor patru paratiroide, caracterul global patologic al ţesutului glandular neoferind nici chiar după secţiune porţiuni aparent normale care să poată fi conservate sau transplantate.

De altfel în toate specimenele examinarea microscopică a identificat hiperplazia nodulară sub formă de microformaţiuni alcătuite din celule principale şi mai puţin celule clare sau oxifile dispuse acinar sau trabecular care alături de aspecte degenerative, scleroza, necroza, zone chistice sau încărcate cu hemosiderina interesa practic toata glanda fără „insule" de parenchim normal.

Într-una din primele observaţii de HPR „refractar" tipic care asocia sindromului

clinic şi biologic sever un nodul tiroidian „banal" de 3 cm O, intraoperator au fost relativ usor identificate şi excizate trei paratiroide anormale dar nu şi cea de a patra. Deoarece examenul histopatologic al nodulului menţionat a fost incert s-a practicat o lobistmectomie stângă iar cercetarea la parafină a precizat diagnosticul de carcinom paratiroidian cu celule principale, exereza glandulară devenind astfel totală. Cazul – reprezentând a 26-a observaţie de asociere a HPR în regim de hemodializă cu un carcinom paratiroidian din literatură – a avut o evoluţie postoperatorie favorabilă atât imediată cu ameliorare clinică şi biologică dar şi la 5 ani după paratiroidectomie continuându-si programul de hemodializă fără semne de recidivă sau depozite secundare.

În trei situaţii s-au efectuat şi exereze tiroidiene asociate, două hemitiroidectomii pentru leziuni nodulare (una fiind cea menţionată mai sus) şi o operaţie Dunhill pentru prezenţa unei formaţiuni de 0,5 cm dure descoperite intraoperator care s-a dovedit a fi un microcarcinom papilar tiroidian „ocult".

Excizia ţesutului celulogrăsos retromanubrial nu a fost practicată sistematic, în cazurile în care a fost totuşi executată fiind identificată paratiroida supranumerară (singura din experienţa proprie), un timom benign şi resturi timice involuate la alţi trei pacienţi.

Evoluţia postoperatorie imediată şi pe termen mediu (6 – 60 luni) a fost în general favorabilă.

S-a înregistrat un hematom postchirurgical care a impus reintervenţie şi drenaj iar trei bolnavi au prezentat hipocalcemie pasageră (5,2 – 8,4 mg/dl), doi fiind simptomatici. Toti operaţii au primit solutii calcice şi preparate de vitamina D, ultimele fiind recomandate şi la domiciliu.

În timp, evoluţia clinică a fost spectaculoasă, evidenţiată mai ales prin dispariţia rapidă a pruritului şi atenuarea fenomenelor dureroase, mai lentă şi incompletă fiind influenţa benefică a paratiroidectomiei asupra asteniei, stării generale şi manifestărilor psihonevrotice.

Valorile calcemiei, fosfatemiei şi FA s-au normalizat sau redus semnificativ comparativ cu cifrele preoperatorii. Nu am avut posibilitatea monitorizării iPTH decât la 6 pacienţi şi la intervale diferite – valorile fiind communicate de centre de dializa situate la distanţă de Iaşi – reducerile fiind însă semnificative.

Cel mai important element în redusa noastră experienţă este faptul că nici unul dintre bolnavi nu a prezentat recidivă clinică sau biologică, fenomene de hipoparatiroidism permanent sau boală adinamică osoasă, toţi continuându-şi programul de hemodializă cu o calitate a vieţii substanţial ameliorată.

DISCUŢII

Tehnicile chirurgicale recomandate actualmente în chirurgia hiperparatiroidismului renal – secundar sau terţiar – redefinit ca boală metabolică osoasă din insuficienţa renală cronică sunt comparate şi dezbătute perrmanent, diverşi specialişti sau echipe străduindu-se să argumenteze avantajele şi superioritatea rezultatelor fiecareia dintre ele.

În mod tradiţional, paratiroidectomia subtotală – prin aparenta expeditivitate – şi respectiv paratiroidectomia totală cu autotransplant – metoda preferată de şcoala japoneză care exclude teoretic posibilitatea reinterventţiilor cervicale - sunt alternativele recomandate majoritar.

Obiectivul principal al ambelor proceduri este reducerea – relativ aproximată – a parenchimului glandular hipersecretor. Inadecvarea cantităţii şi calităţii ţesutului paratiroidian conservat conducând în timp la apariţia în 5 – 80% din cazuri a unor persistenţe sau recidive – dificil de evaluat şi tratat, mai ales chirurgical, au stimulat în ultimele două decenii reconsiderarea în cazuri bine selecţionate a exerezei parati-

roidiene totale.

Experienţa este limitată la câteva studii însumând sub 200 observaţii în care s-au obţinut rezultate încurajatoare şi stabile în timp, fără boală adinamică osoasa ori hipocalcemie simptomatică, întrutotul comparabile, dacă nu superioare, celorlalte metode.

Pentru unii autori, eliminarea totală a ţesutului paratiroidian – definită prin anularea sau valoarea postchirurgicala sub 1 ng/l a iPTH – apare ca imposibilă, deoarece în dezvoltarea embriologică a acestor glande de-a lungul traiectului de migrare în regiunea cervicală şi mediastin persistă unele „cuiburi" de ţesut glandular funcţional supus aceloraşi factori de stimulare ca şi cel care alcătuieşte paratiroidele propriu zise eu sau ectopice. În condiţiile unei îndepărtări chirurgicale totale a glandelor patologice, aceste resturi pot asigura o secreţie hormonală convenabilă (ceea ce nu se întâmplă după exereza inadvertentă a tuturor paratiroidelor normale întâlnită cateodată în chirurgia acestui teritoriu).

Din punct de vedere tehnic, hipertrofia impresionantă în unele observaţii – depăşind 1 – 2 cm O, facilitează evidenţierea şi chiar disecţia şi exereza acestor glande, fapt observat şi în cateva din cazurile noastre. Oricum dificultăţile date de vechimea, dimensiunile, raporturile sau eventualele anomalii topografice sunt incomparabil inferioare celor din reintervenţii.

În sfarsit, în cadrul monitorizarii postchirurgicale complianţa bolnavilor autohtoni la evaluare periodică, compensare calcică sau administrare de vitamina D pare favorizată de prezentarea prelungită în timp la şedintele de hemodaliză aşadar superioară comparativ cu mulţi dintre pacienţii cărora li s-a practicat o tiroidectomie totală care evoluează inexorabil către hipotiroidism definitiv.

Ambele suferinţe întră în cadrul patologiei sociale, definitorie şi pentru una din principalele indicaţii ale paratiroidectomiei totale în HPR şi anume lipsa posibilităţilor şi/sau perspectivei de a efectua un transplant renal (uneori chiar şi eşecul acestuia ca în cele două observaţii ale noastre.

Acest criteriu, împreună cu celelalte de ordin anamnestic, clinic-evolutiv şi lezional pot constitui elementele unei selecţii riguroase a bolnavilor, în care se recomandă a aplica această tehnică, singurele care pot asigura rezultatele postoperatorii favorabile preconizate pe termen scurt şi mediu.

Desigur rămâne obligatorie o urmărire prelungită în timp a acestor cazuri, completată de o ajustare medicamentoasă calcică şi vitaminică adecvată, pentru a certifica paratiroidectomia totală ca un procedeu rezonabil şi a o aşeza alături de celelalte tehnici chirurgicale folosite actualmente pentru această patologie.

În concluzie, alături de posibilitatile tratamentului medical, cele trei tehnici de paratiroidectomie îşi dispută indicaţiile, avantajele şi succesele în managementul hiperparatiroidismului renal. Reconsiderarea paratiroidectomiei totale în cazuri bine selectate de hiperfunctie paratiroidiana severă, refractară la orice medicaţie şi care nu au perspectiva practică a unui transplant renal, oferă în condiţiile unei morbidităţi inferioare celorlalte proceduri – în special anularea riscului de recidivă – efecte simptomatice evidente, cu absenţa surprinzătoare a hipoparatiroidismului postoperator, stabile în timp.

EXPECTATION FROM COCHLEAR IMPLANTATION IN PATIENTS WITH LONG-TERM PRELINGUAL DEAFNESS (Abstract): Cochlear implantation is a well-established method of treating bilateral profound cochlear deafness. One should be aware that the medical literature is quite poor, in regard to the outcomes of the implantation of adolescents or adults with prelingual deafness. The aim of this study is to evaluate the audio-verbal outcome in late implanted adolescents and adults with congenital deafness. **Material and methods**: the study included 8 late implanted patients with bilateral profound deafness 4 of them were implanted as adolescents and the other 4 as adults; all of them were implanted at the Clinical Rehabilitation Hospital from Iasi. The patients' hearing abilities were tested using 2 scales: Speech Perception Rating Scale and Speech Intelligibility Rating Scale. **Results**: all of the patients have benefited from the implant when their hearing performances were compared to those before implantation. **Conclusions:** the topic remains open as long as the studies had only a limited number of subjects, but even so it can be affirmed that, with no doubt, all the subjects have had significant improvements after implantation. **Keywords:** LATE COCHLEAR IMPLANTATION, PRELINGUAL DEAFNESS.

Cochlear implantation is a well-established method of treating bilateral profound cochlear deafness. In the beginnings of the cochlear implant era, the cochlear implants were used to treat only the post linguistically deaf adults. Later on, due to the success encountered with the adults, the cochlear implant teams were stimulated to go further, so they started to implant small children with congenital hearing loss, as well. After half a century of cochlear implantation, plenty of scientific papers regarding this subject matter have been written, especially on the results obtained with small children with congenital deafness and with adults with post linguistic hearing loss (1-4). The results of the cochlear implantation depend on numerous variables such as: the age of onset of deafness, the presence of residual hearing, the duration of hearing loss, the communication mode before implantation, the age at implantation, the cause of deafness, and so on. All authors

agree now that the most important of these predictive factors are the duration of the deafness for the adults with prelingual hearing loss and the age of implantation for the children with congenital deafness (5-7).

The issue is, however, more complex because, even among small children with apparently same characteristics (congenital hearing loss, small age at implantation), there are significant differences in the audio-verbal gain after implantation.

Things are much more complex when it comes to the borderline candidate: the teenagers and adults with prelingual deafness, the patients with residual hearing, the patients with single side deafness or with chronic otitis media, and so on. These patients were not included among those who had received traditional recommendations for cochlear implantation.

Regarding the outcomes of the implantation of adolescents or adults with prelingual deafness, the medical literature is quite poor. Even so, it seems that there are two different trends of opinions: some of the authors advocate that, in spite of a poor auditory-verbal improvement the patients will still benefit from the late implantation mainly because of the psycho-social implications while the other category of authors asserts that the implantation of such patients is useless (8).

The aim of this study is to evaluate the audio-verbal outcome in late implanted adolescents and adults with congenital deafness.

MATERIAL AND METHODS

The longitudinal study included 8 late implanted patients with bilateral profound deafness: 4 of them were implanted as adolescents and the other 4 as adults.

All of them were implanted at the Clinical Rehabilitation Hospital from Iasi. The preoperative evaluation was performed using the standard protocol for the candidates to cochlear implantation (history of illness, clinical, genetic and functional evaluation of the ear, CT and RMN of the temporal bone) (9). The approach was through the posterior tympanotomy and cochleostomy; the electrode array was fully inserted in all cases (10). There were no accidents or complications during or after surgery. The first fitting was performed 4 to 6 weeks after the surgery. After implantation, all patients were included into an intensive audio-verbal rehabilitation program.

The patients were evaluated at 1, 3, 6, 12 months after the first fitting and, after that, yearly, up to 7 years. Two tests were used: Speech Perception Rating Scale and Speech Intelligibility Rating Scale.

The Speech Perception Rating Scale (tab. I) includes 7 items from 0 to 7 which allowed estimation of the progress of each patient after the cochlear implantation. To evaluate speech perception abilities, we assumed that hearing improvements are made in a hierarchical fashion starting from simple sound detection to comprehension of spoken words. Testing followed this hierarchy and patients were required to reach criteria scores for each level before moving to the upper level.

The Intelligibility Rating Scale (tab. II) includes 5 items intended to estimate, from 1 to 5, the evolution of speech production of the patient. We obtained scores either from familiar or from unfamiliar listeners.

Both tests asses the improvements of each recipient and compare the results obtained for all 8 patients.

TABLE I
Speech Perception Rating Scale

0	No detection of environment sounds
1	Speech detection
2	Discrimination between speech and
3	Closed-set word identification based
4	Closed-set word identification based
5	Open-set word recognition without
6	Sentence recognition with a family
7	Can use phone with a family member

TABLE II
Intelligibility Rating Scale

1	Imitation of examiner's spoken model
2	Elicit picture naming (isolated words)
3	Sentences recognized by familiar listeners
4	Sentences could be understand easy by unfamiliar
5	Is easy understand by unfamiliar listener in daily living

RESULTS

As the result of the evaluation before implantation, the patients were diagnosed with bilateral profound congenital cochlear deafness. The age at implantation ranged between 9 and 35 years. The duration of implant use was between 1 and 7 years, with a median of 3 years and an average of 3 years and 3 months; 6 of the patients were females and 2 of them were males.

All patients were fitted with conventional hearing aids prior to implantation with no benefit. The IQ and psychological development of all patients was normal (11).

Five of the patients had no communication mode prior to implantation, two patients were sign language and lip-reading users, and one patient used oral communication and lip-reading.

TABLE III
Results of cochlear implanted patients
("pre" means the patient had the ability before implantation)

No. of case	Age at CI (years)	Speech Perception rating scale								Speech Intelligibility rating scale					IC use (in years)
		0	1	2	3	4	5	6	7	1	2	3	4	5	
1	12	pre	1	3	6	12	36	42	42	3	9	12	36	36	9
2	10	pre	1	3	6	12				3	9	24			7
3	12	pre	1	3	6	12				3	6	12			1
4	9	pre	1	3	12					3	12				1
5	18	pre	1	3	9	12				3	Pre	pre	pre		3
6	19	pre	1	3	9					3	Pre	pre			6
7	30	pre	1	2	5					3	Pre	pre	pre		1
8	35	pre	1	3	9					3	9	12			6 y

The results obtained with the cochlear implants are presented in the table III. The numbers from the first row represent the scores for the two tests used for evaluation, from 0 to 7 for the Speech Perception Rating Scale and from 1 to 5 for the Speech

Intelligibility Rating Scale. The first four cases from the table are the adolescents and the last are the adults. The period the implant was used, necessary to reach each level, is expressed in months passed from the first fitting. The results show that all the patients included in the study have benefited from the implant when comparing their current hearing abilities with their hearing performances before implantation. They wear their implant daily.

DISCUSSION

Even as early as 1987, in a paper published during that period, G. Clark had drawn the conclusion that the age of deafness onset, the age at implantation, and the motivation of the patient play a major role in the outcome of cochlear implanted persons (12).

In congenitally deaf children, if the implantation is done very early, the outcomes are comparable with the normal hearing child. A matter that is often overlooked is that actually, in a group of children with the same characteristics, implanted very early, after 3-4 years of implant use the results would not be the same for each of them.

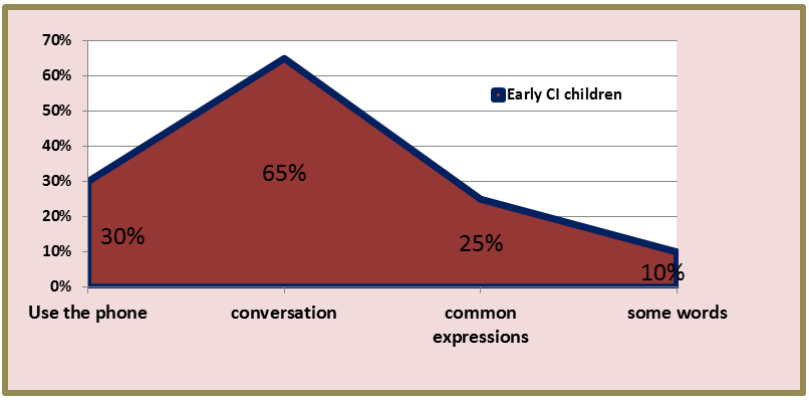

Fig.1. Results after cochlear implantation

In a study published in 2005, B. Krahulcova shows that only 65% of these children are able to understand a conversation without lip-reading and 30% of them are able to use the phone (13); 25% can understand simple sentences and the remaining 10% can understand isolated words (fig. 1). It is possible to presume that, to a certain extent, the same happens with late implanted patients with congenital deafness: some of them may have better outcomes than others. We do not have yet any way of knowing preoperatively who the best candidates from this group are. The debate regarding these patients is once more justified as long as it is not possible to quantify the risk/benefit ratio in these subjects8. At last, but not at least, it is important not to overlook the financial aspects.

Regarding our patients, the individual variability regarding to the age of implantation, the length of implant use (14), the communication mode prior to implantation etc. are reflected in the outcomes of audio-verbal rehabilitation post implant (15). These differences determine us to assess separately each subject.

When assessing the audio-verbal improvements from the day of the first fitting until today, we found that even for these

subjects the age at implantation makes a great difference concerning the outcomes. The patients implanted as adolescents score higher either at Speech Perception Rating Scale or Speech Intelligibility Rating Scale than those implanted as adults. The progress made by adolescents is gradual thus, in the most successful case, after 4 years of implant use (case number 1) with a sustained rehabilitative program and with a consistent familial support, one of the adolescents, implanted at 12 year of age, is able to speak on the phone and can be understood by an unfamiliar listener. Some authors argue that the poor outcomes of this group are not due to the absence of the auditory stimulus but to the lack of knowledge about the acoustic structure of the oral language (16). So, they affirm that subjects that are educated in an oral manner prior to implantation may be capable, after the implantation, to integrate the sounds they perceive (17, 18). In our study, although the patients had been using sign language before implantation, the outcomes, after 4 years of implantation, are quite remarkable. Yet, this success may have some other, unknown yet, explanation.

The expectations regarding the outcomes of our patient who had the implantation when she was in her '30s and benefited from oral communication prior to this procedure should be high if we believe the theory that argues that oral communication facilitates the outcome in the late implanted subjects. Taking into consideration that only one year has passed since the implantation, we can presume that better results are to be expected. At the same time, in a paper published in 2004 by Teoh it is shown that for prelingual deaf adults the maximum benefit is reached at the end of the first year following the implantation with no further improvement and the performance achieved by this group of patients is significantly below the levels of hearing achieved by post lingual patients (19, 20).

This was the case for the other three adult patients who had used their implants for more than 3 years and whose progress, compared to that of the prelingual deaf adolescents with implants, ceased at a lower level after the first 9 to 12 months following the implantation.

The results of our study indicate that prelingual deaf persons implanted in adolescence do better when compared to those implanted as adults. Only one exception was found, a patient who has had limited benefits from the implant, so far, in comparison with the others from the adolescent group, even though she was implanted at a younger age (case 4). The explanation for this is the presence of a malformation of the cochlea – common cavity (21).

CONCLUSIONS

The topic remains open as long as the studies had only a limited number of subjects, but even so it can be affirmed that, there is no doubt that all the subjects included in this study have had significant improvements after implantation.

ARACHNOID CYST ASSOCIATED WITH PYLORIC STENOSIS IN A YOUNG BOY (Abstract): An unusual association between an arachnoid cyst and a decompensated pyloric stenosis in a three years-old boy is presented. The little patient was admitted into hospital with haematemesis, melena, influenced generally condition and acute posthemorrhagic anaemia following aspirin intake for hypertermia. Specific intensive care was successful and the little patient was discharged but without an upper digestive endoscopy(parents refusal, technical reasons). After one week he returned with progressive worsening vomitings and an intracranial hypertension was suspected. CT documented an arachnoid cyst in the right middle cranial fossa and the patient is directed to the Neurosurgical Clinic where a cyst fenestration was done. Subsequent to operation the vomitings reinstaled with severe dehydration and an upper GI series showed a decompensated pyloric stenosis. He was operated on underwenting an antrectomy. Finally the child recovered with good short and long-term evolution. The coincidental presence of an intracranial congenital mass and a complicated aspirin-induced peptic ulcer in this young patient, misleaded us and in the lack of an early endoscopy an intempestive neurosurgical operation was initially done. **Key words**: ARACHNOID CYST, ASPIRIN, ULCER, PYLORIC STENOSIS, ENDOSCOPY

În practica pediatrică vărsăturile constituie un simptom frecvent întâlnit, atât în afecţiuni digestive cât şi extradigestive. Diagnosticul diferenţial al acestora este deseori dificil, mai ales în situaţii în care asocierea unor entităţi patologice are ca expresie clinică sindromul dispeptic. Masele cerebrale intra sau extraparenchimatoase pot avea drept consecinţă apariţia sindromului de hipertensiune intracraniană, semnalat la copii mici de cefalee şi vărsături alături de modificări ale fundului de ochi. Chisturile arahnoidiene sunt formaţiuni benigne care apar în axul cerebrospinal la nivelul arahnoidei şi care nu comunică cu sistemul ventricular. Ele reprezintă 1% din totalul maselor intracraniene iar marea majoritate sunt anomalii congenitale. În general leziunile devin simptomatice în prima copilărie astfel că între 60 şi 90% dintre pacienţi sunt copii (1). În marea majoritate a cazurilor diagnosticul este stabilit incidental în cursul unor investigaţii imagistice recomandate pentru alte afecţiuni. Ulcerul secundar la vârsta pediatrică poate apare în contextul administrării unei medicaţii cu efect gastrotoxic. Leziunea debutează în general printr-o complicaţie de tip hemoragie sau perforaţie dar se poate

manifesta şi prin sindrom funcţional digestiv ce asociază vărsături şi dureri abdominale (2). Prezentăm în continuare un caz de asociere între ulcer secundar la aspirina complicat cu stenoză pilorică şi chist arahnoidian temporal drept la un copil de 3 ani.

PREZENTAREA CAZULUI

Pacientul M.I. în vârstă de 3 ani de sex masculin, din mediul rural, normal dezvoltat staturo-ponderal (T = 101 cm, G = 17 kg) se internează în urgenţă în Secţia de Terapie Intensivă a Spitalului Clinic de Urgenţă pentru Copii „Sf. Maria" pentru hematemeză şi melenă apărute la 48 de ore dupa administrarea de către părinţi a unei jumătăţi de tabletă de aspirină în scop antitermic. La internare copilul prezenta stare generală influenţată, paloare, faringe intens congestiv, amigdale hipertrofice, tahicardie (AV = 130/min), suflu sistolic gr. II/6 în toate focarele, epigastralgii intense, vărsături în zaţ de cafea, melenă. Investigaţiile paraclinice au relevat anemie posthemoragică acută (Hb cu valori ce au variat între 9,9 şi 6,5 mg/dL), leucocitoză cu neutrofilie (GA = 15600/mm^3; PMN = 79%), hipoglicemie (65 mg/dL), hiponatremie (128 mmol/L), hipopotasemie (2,8 mmol/L); uree cu valoare crescută (50 mg/dL), coagulograma normală (TQ = 14,5 sec, APPT = 36 sec, INR = 1).

Radiografia toraco-abdominală a fost de asemenea normală. Sub tratament cu antiacide, antisecretorii i.v, hemostatice, transfuzii de masă eritrocitară, antibioterapie cu spectru larg pentru infecţia respiratorie intercurentă, starea generală se ameliorează, vărsăturile şi durerile epigastrice dispar, tranzitul intestinal se normalizează. Menţionăm că, deşi indicaţia ar fi fost certă, nu s-a efectuat endoscopie digestivă superioară datorita refuzului părinţilor şi unor motive tehnice. Pacientul se externează ameliorat recomandandu-i-se terapie marţială pentru corectarea anemiei dar revine peste o săptămână cu sindrom de deshidratare acută prin vărsături. Examenul clinic evidenţiază stare generală influenţată, scădere ponderală de 2 kg, G = 15 kg, facies încercănat, paloare, semne de deshidratare şi vărsaturi incoercibile alimentare şi bilioase, lipsa tranzitului intestinal pentru materii fecale de 48 de ore, absenţa semnelor de iritaţie meningeană.

Paraclinic: anemie hipocromă microcitară (Hb = 9,3 mg/dL, VEM = 69 μ^3, MCHC = 28 g/dL, MCH = 22 pg), leucocitoză cu neutrofilie (GA = 17600/mm^3, PMN = 81%), hipopotasemie (K = 2,4 mmol/L), hiponatremie (Na = 121 mmol/L), hipocloremie (Cl = 90 mmol/L), alcaloză metabolică (RA = 30mEq/L).

Ecografia, radiografia abdominală pe gol şi examenul chirurgical infirmă un sindrom ocluziv.

Cu tot tratamentul energic de reechilibrare hidroelectrolitică şi acido-bazică vărsăturile alimentare şi bilioase persistă. Examenul neurologic şi fundul de ochi nu arată modificări patologice dar pentru a exclude un eventual sindrom de hipertensiune intracraniană se efectuează tomografie computerizată care evidenţiază un chist arahnoidian voluminos (4,5/4,5 cm) dez-

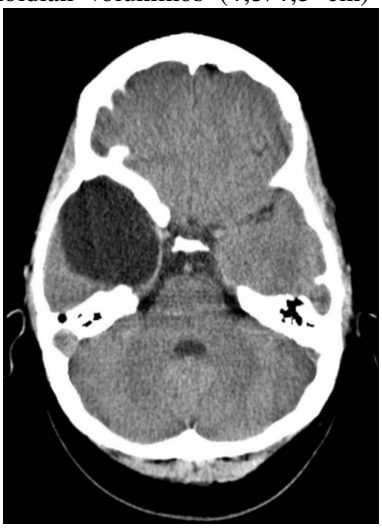

Fig. 1. CT craniocerebral (secţiune axială): chist arahnoidian drept (M.I, 3a)

Fig. 2. Tranzit baritat : Stenoză pilorică (M.I, 3a)

voltat în valea sylviană şi temporo-polar drept, neînsoţit de hidrocefalie activă ; structurile liniei mediane în poziţie normală şi mega cisterna magna (fig. 1). Pacientul este transferat la Spitalul de Neurochirurgie Iaşi unde se practică intervenţia chirurgicală (fenestrarea chistului şi liza aderenţelor prin craniotomie frontotemporală dreaptă). Este readmis în serviciul nostru unde, după o evoluţie postoperatorie favorabilă de doar două zile, reapar vărsăturile incoercibile şi modificările hidroelectrolitice consecutive. Tranzitul baritat indică un aspect caracteristic de stenoză pilorică (fig. 2).

Laparotomia efectuată în Clinica de Chirurgie Pediatrică evidenţiază un stomac dilatat cu pilor de aspect pseudotumoral, mult mărit de volum, cu leziune ulceroasă şi edem important al mucoasei (fig. 3). Se practică rezecţia zonei (antrectomie) şi refacerea continuităţii digestive prin gastroduodenostomie Pean-Bilroth I. Examenul anatomopatologic al piesei de rezecţie confirmă diagnosticul de leziune ulceroasă. Ulterior, evoluţie favorabilă cu drenaj minim nazogastric şi abdominal, cu reluarea tranzitului pentru materii fecale şi gaze a patra zi postoperator când se suprimă şi drenurile. Externat a 7-a

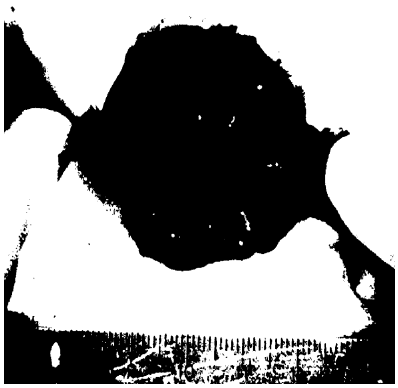

Fig. 3. Piesa operatorie

zi postoperator pacientul revine la control după 6 săptămâni, când se efectuează nou tranzit baritat ce indică un aspect normal ; controalele anuale ulterioare arată o evoluţie favorabilă cu curbă ponderală ascendentă şi parametri biologici în limite normale.

DISCUŢII

Descrise pentru prima data de Bright în 1831, chisturile arahnoidiene sunt leziuni congenitale sau pot apărea în asociere cu tumorile sau cu aderenţele determinate de meningite, hemoragii sau intervenţii chirurgicale (3). Cam 50-60% apar în fosa craniană mijlocie. Afecţiunea interesează mai frecvent sexul masculin (2-3/1) şi se localizează predominant pe partea stânga, leziunile bilaterale sau multiple fiind rar semnalate (1,3). Au fost raportate cazuri cu agregare familială, precum şi asocieri între chisturi arahnoidiene bilaterale la nivelul scizurii sylviene şi acidurie glutarică tip I, sindrom Marfan, neurofibromatoză sau boala rinichiului polichistic (4,5). Simptomatologia include cefalee, greţuri, vărsături, somnolenţă, întârziere în dezvoltarea psiho-motorie, semne de focar, convulsii ; chisturile supraselare mai pot avea ca expresie clinică hidrocefalia, pubertatea precoce, alterări ale acuităţii vizuale şi „head bobbing”

(mişcari de flexie şi extensie ale capului). Ultrasonografia este utilă în perioada fetală şi pe parcursul primului an de viaţă, fiind neinvazivă şi având un randament apreciabil în detectarea maselor intracraniene (1,3). Radiografia de craniu are o sensibilitate redusă; la copii poate arăta craniomegalie, mărirea fontanelei anterioare şi subţierea oaselor bolţii craniene, modificări care pot fi însă variante ale normalului (1,3). Tomografia computerizată relevă structuri unilaculare sau septate, cu margini nete, conţinut izodens cu LCR şi modificări minime ale ţesutului cerebral subiacent; rar apar calcificări. Utilizarea CT poate duce la erori de diagnostic, mai ales în cazul chisturilor hemoragice, al căror conţinut are o densitate diferită faţa de LCR. De asemenea, CT nu poate face diferenţierea faţă de chisturile epidermoide. Investigaţia imagistică de elecţie rămâne RMN care determină cu precizie locaţia, extinderea şi raportul cu ţesutul cerebral sau coloana vertebrală în cazul chisturilor spinale. Se poate practica RMN folosind secvenţa de difuzie si secvenţa FLAIR (fluid-attenuated inversion recovery), dar cea mai sensibilă rămâne PC-RMN (cine phase-contrast magnetic resonance imaging) (6,7). Angiografia este rar practicată deoarece metodele non-invazive ca angio CT sau angio RMN au aceeaşi acurateţe diagnostică. În ceea ce priveşte tratamentul opiniile sunt împărţite între tendinţa de a trata doar chisturile clinic manifeste şi cea de a practica decompresia leziunilor asimptomatice pentru a evita viitoare complicaţii. Opţiunile terapeutice sunt controversate şi includ fenestrarea deschisă sau endoscopică, plasarea unui şunt chistoperitoneal sub ghidaj ultrasonografic sau aspiraţia stereotaxică. Reacumularea postoperatorie de lichid a fost descrisă în până la 25 % dintre cazuri (3,8).

Utilizarea aspirinei la copii este limitată în prezent la pacienţii cu reumatism articular acut, artrită reumatoidă juvenilă sau boala Kawasaki mai ales datorită riscului de apariţie a sindromului Reye dar şi al altor entităţi patologice ca ulcerele peptice secundare. Aspirina este formal contraindicată în combaterea febrei la vârsta pediatrică iar utilizarea pe scara largă a ibuprofenului în scop antitermic a facut ca acesta să devină principalul factor implicat în lezarea mucoasei gastroduodenale la copil (2). Efectele gastrotoxice ale AINS sunt atât directe cât şi sistemice (inhibarea sintezei de prostaglandine). Administrarea de AINS este urmată de apariţia unor hemoragii gastrice subepiteliale şi ulterior de apariţia eroziunilor mucoasei dacă expunerea continuă (9). AINS inhibă ciclooxigenaza COX-1 implicată în producerea prostaglandinelor cu efect protector care reglează integritatea mucoasei gastrice, homeostazia plachetară şi funcţia renală. Scăderea agregării plachetare şi prelungirea timpului de sângerare cresc riscul de hemoragie digestivă superioară. Aspirina şi cele mai multe AINS scad proprietăţile hidrofobe ale stratului de mucus, secreţia de bicarbonat şi sunt asociate cu efecte iritante topice (9,10). Ulcerul produs de aspirină debutează prin accident hemoragic la copiii mici iar localizarea este predominant gastrică. Arsenalul terapeutic include prostaglandinele de sinteză, inhibitorii H2 şi IPP. În general, are prognostic bun dar se descrie posibilitatea formării unui diafragm antral prepiloric într-un interval cuprins între o lună şi 2 ani (11).

În observaţia noastră, deşi elementul anamnestic şi simptomatologia clinică iniţială (hemoragia digestivă superioară) orientau către diagnosticul de ulcer secundar, neefectuarea în urgenţă a endoscopiei digestive superioare alături de evoluţia iniţial favorabilă sub tratament antisecretor au condus la ignorarea leziunii ulceroase care s-a complicat rapid cu o stenoză pilorică. În momentul reinternării ne-am aflat în faţa unui sindrom dispeptic cu semne de deshidratare

acută ; aspectul vărsăturilor nefiind caracteristic s-a impus un diagnostic diferenţial al etiologiei acestora care a inclus şi sindromul de hipertensiune intracraniană. Coincidenţa asocierii cu leziunea malformativă a condus la intervenţia neurochirurgicală intempestivă, a carei indicaţie rămâne discutabilă având în vedere că evoluţia ulterioară şi evidenţierea prin tranzit baritat a stenozei pilorice au stabilit cauza reală a dispepsiei şi au dus la rezolvarea chirurgicală adecvată. Asocierea chistului cu mega cisterna magna şi evoluţia rapid stenozantă a ulcerului particularizează suplimentar acest caz de coexistenţă a patologiei tumorale intracraniene cu cea digestivă.

CONCLUZII

Cazul prezentat ilustrează posibilele consecinţe ale administrării intempestive de către aparţinători a unei medicaţii agresive pentru mucoasa gastroduodenală, a cărei utilizare la copil trebuie atent supravegheată. Considerăm că explorarea endoscopică se impune ca gest de primă-intenţie în hemoragiile gastrointestinale, imediat ce statusul bolnavului o permite. Nu în ultimul rând, originea extradigestivă a unui sindrom dispeptic va fi luată în discuţie după eliminarea sistematică a tuturor cauzelor digestive.

COMPARISON BETWEEN DIGITAL MAMMOGRAPHY AND DIGITAL BREAST TOMOSYNTHESIS IN THE DIAGNOSIS OF BREAST CANCER (Abstract): The purpose of this study was to evaluate the impact of adding digital breast tomosynthesis (DBT) to digital mammography (DM) on the detection and characterization of breast lesions and to compare the diagnostic performance of DM and DBT in order to determine whether or not simultaneously viewing is more informative in detection of breast cancers. **Material and methods:** We retrospectively reviewed the records of 58 female patients (age 38 to 79 years old), who had pathologically proved breast cancers and had undergone both DM and DBT during a period of eight month (between February and September 2018). The diagnostic performance of each modality was evaluated. **Results:** The sensitivity of DM was 73% and its specificity was 47%, respectively the sensitivity of DBT was 98% and specificity 73%. The positive predictive value was 0.81 for DBT, while DM had a positive predictive value of 0.58. The negative predictive value was 0.98 in DBT and 0.62 in DM. The margins of the mass lesions and inhomogeneity of the focal asymmetric densities were better evaluated on DBT. Distributions and morphology of microcalcifications were better characterized on digital mammography than on tomosynthesis. **Conclusions:** In our study, DBT significantly enhances the detection and characterization of tumors in the context of mass lesions and focal asymmetric densities. **Keywords:** MAMMOGRAPHY, TOMOSYNTHESIS, BREAST CANCER.

Breast cancer remains one of the leading causes of death in women over the age of 40 years. Mammography is an effective imaging tool for the detection of early-stage breast cancer. The sensitivity of screening mammography for breast cancer had been reported to be 80-90% in adipose breast but may be as low as 48% in extremely dense breast because of overlapping dense fibro glandular breast tissue, which poses a significant obstacle to interpretation by reducing the conspicuity of breast lesions (1, 2, 3). Digital breast tomosynthesis (DBT) is a new tool which eliminates tissue overlap due to its ability to acquire 3D images of the breast and is considered one of the most challenging and promising up to date imaging technology (4, 5). Several studies have shown that tomosynthesis may offer superior diagnos-

tic accuracy when compared with digital mammography (DM), not only in the routine diagnostic practice, but also in breast cancer screening, for the evaluation of breast lesions (6, 7). It was considered that 3D breast tomosynthesis using the cranio-caudal (CC) and medio-lateral oblique (MLO) views diminish false-positive findings, minimize the masking effect of overlying tissue and enable improved cancer detection while (8, 9, 10).

The purpose of this study is to evaluate the impact of adding DBT to DM for the detection and characterization of breast lesions and to compare the diagnostic performance of DM and DBT in order to determine whether or not simultaneously viewing is more informative in the detection of breast cancer.

MATERIAL AND METHODS

We retrospectively reviewed 69 pathologically proven breast cancers found at 58 female patients who had undergone both DM and DBT during a period of 8 month (between February and September 2018). The mammographic findings included the density of breast, the type of malignant features (focal asymmetric density) and breast imaging reporting and data system (BIRADS) score. A combined DM and DBT examination was performed with a SenoClaire GE mammography unit in 2 views: CC and MLO; the system attains a "Combo-mode" imaging technique (2D + 3D imaging) that acquires a digital mammogram and a tomosynthesis during a single compression. The tomosynthesis consist of nine low-dose images of the breast are acquired at different angles while the X-ray tube moves in a 25º arc across the breast. These images are then used to produce a series of one-millimeter thick images (from 60 to 90 slices) that can be reconstructed to a three-dimensional (3D) image of the breast. Images were displayed on a dedicated diagnostic mammography workstation with special capabilities that are tailored for breast imaging. The reconstructed tomosynthesis images can be viewed slices, slabs or in a cine loop manner.

We identified breast lesions with DM and DBT and the following parameters were characterized: dimension, number, morphology and distribution of the calcifications in order to classification them in benign, intermediate or malignant; intensity; homogeneity and margins (convex or concave) of the mass lesions.

Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy of either modality were calculated with histology as the gold standard. When evaluating imaging modalities, these results were classified into two categories: a positive test result is any of BI-RADS assessment categories 0, 4 or 5 and a negative test result is any of BI-RADS assessment categories 1, 2, or 3. A true positive is a positive imaging finding that is followed by a diagnosis of breast cancer within 12 months. A false positive is a positive imaging result that is not followed by a cancer diagnosis within 12 months. True negatives are the negative test results that remain negative during follow-up. False negatives are the negative test results with cancer detected at histopathological examination. The sensitivity is defined as the number of positive tests in breast cancer patients divided by the total number of women, and was reported as a percentage. The specificity is defined as the number of true negative cases divided by the true negatives and false positives. The

positive PPV is the number of true positives divided by the total number of positive tests. The NPV is the number of true negatives divided by the total number of negative tests. All statistical tests were performed with MedCalc for Windows (MedCalc Software, Mariakerke, Belgium). Imaging findings were tabulated and categorical results of DM and DBT were included. Both modalities were compared with the histopathology report in the context of detection and diagnosis, each was individually assessed, using the Pearson Chi Square tests. P value <0.05 is considered to be significant.

RESULTS

All patients were female. The average age of patients was 48 years (ranging from 38-79 years). Among the 69 malignant breast lesions identified, we discovered 18 (26.08%) clusters of microcalcifications (three clusters of more than 15 amorphous microcalcifications, BIRADS 4c, and 15 cases with more than 20 pleomorphic microcalcifications with segmental orientation BIRADS 5, 45 (65.21%) mass lesions and 6 (8.69%) focal asymmetric densities which were classified BI-RADS 4c and 5 according to Breast Imaging Reporting and Data System atlas (11) (fig.1).

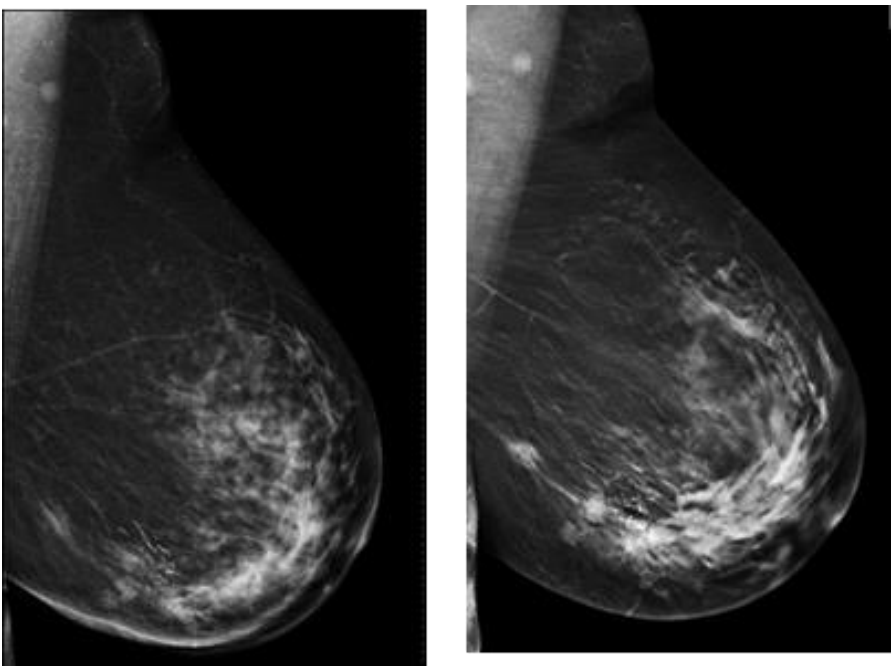

Fig. 1. Cluster of BI-RADS 5 microcalcifications on digital mammography (a) and breast tomosynthesis (b)

The malignant lesions were correctly diagnosed by DM in 58 cases (84%) (18 out of 18-100% clusters microcalcifications, 40-88.89% out of 45 mass lesions); the estimation became more accurate when DBT was included in the evaluation of the mass lesions (all 45 cases were classified BIRADS 4c and 5) and the focal asymmetric densities (5 out of 6 lesions were classified BIRADS 4c). Tomosynthesis elimi-

nates tissue overlap and the margins of the masses were better depicted on DBT than on DM (39 spiculated and 6 micro lobulated margins were very well seen); DM couldn't evaluate correctly the margins of the masses in 9 (20%) cases, which appeared to have indistinct margins. DM and DBT evaluated correctly the intensity of all 45 masses (36 high intensity and 9 medium intensity) (fig. 2).

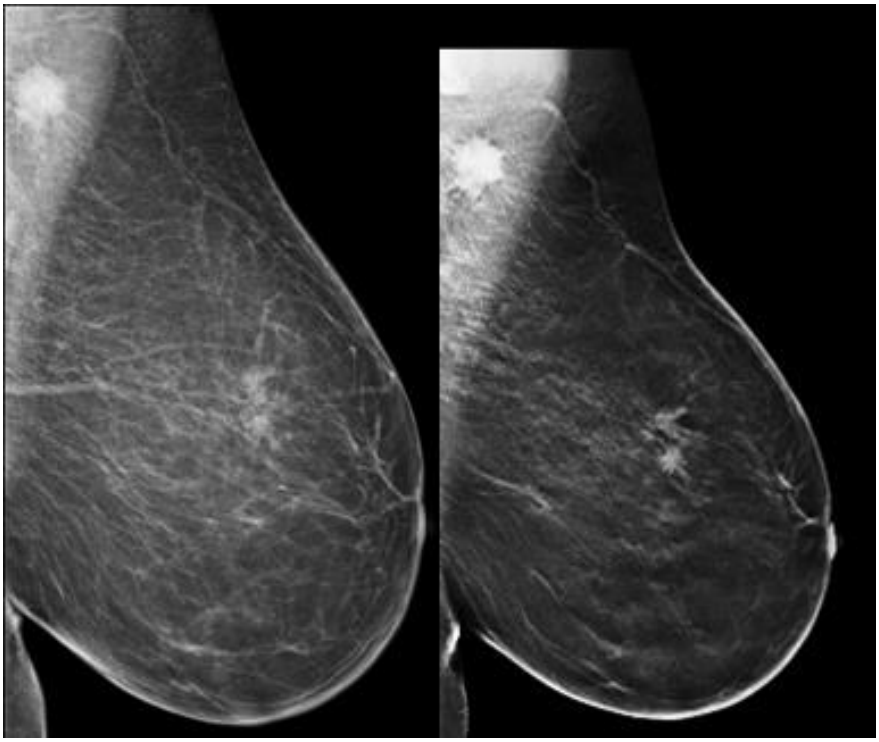

Fig. 2. Two malignant breast tumors and axillary lymphadenopathy – the margins of the masses are better evaluated on breast tomosynthesis (b) than on digital mammography (a)

In 5 cases the presence of convex margins, which indicates a possible malignancy were better seen on DBT (fig. 3).

A significant difference in diagnostic performance ($p \leq 0.05$) between DM and DBT was found. The sensitivity of DM was 73% and its specificity was 47%, respectively the sensitivity of DBT was 98%, and specificity 73% ($p = 0.04$, Pearson's chi-squared test). The positive predictive value was 0.81 for DBT, while DM had a positive predictive value of 0.58. The negative predictive value was 0.98 in breast tomosynthesis and 0.62 in DM ($p = 0.05$, Pearson's chi-squared test). The inhomogeneity of all focal asymmetric densities was better evaluated on DBT and the higher intensity which was seen inside suggested a malignant lesion; the presence of convex margins, which indicates a possible malignancy were better seen on DBT in 5 cases (fig. 3).

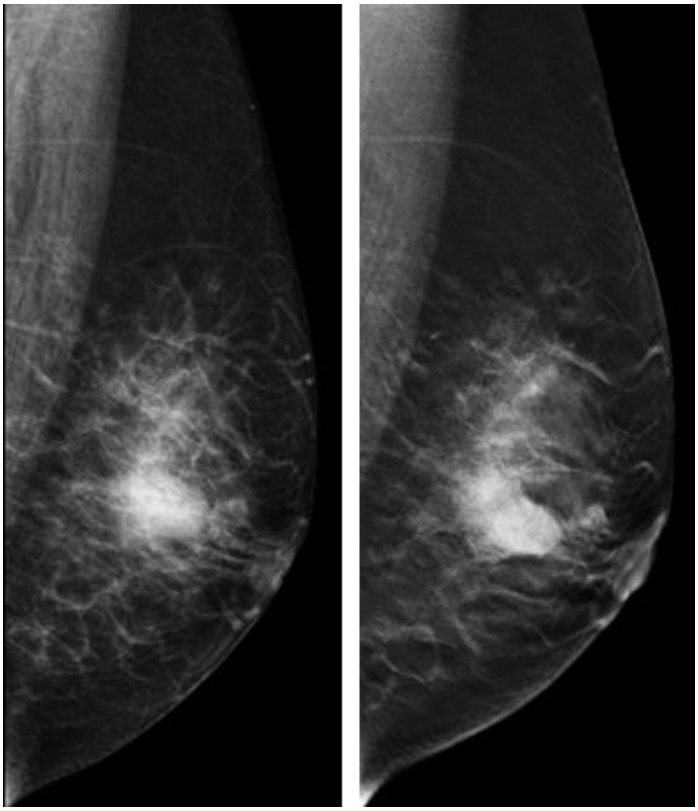

Fig. 3. Focal asymmetric density (BIRADS 4c) visible on digital mammography (a), better depicted on breast tomosynthesis (b)

DISCUSSION

The objective of this study was to evaluate the potential impact of breast tomosynthesis and digital mammography in the detection and diagnosis of breast lesions.

Our results showed an increased sensitivity of 25% (from 73% to 98%) with use of combined DBT and DM, which is consistent with the result of prior studies. Rafferty demonstrated an increased sensitivity from 65.5% for DM alone to 76.2% with the addition of DBT (13). Michell *et al.* in a study of 738 women found an increase in sensitivity of 18% (from 40% to 58%) when DBT with DM was compared with DM alone (14). Teertstra *et al.* examined 513 cases of which 109 were cancers, reported similar sensitivity for DBT and DM (92.9%). It should be noted that the authors did not investigate the use of DBT in combination with DM. A borderline significant improvement ($p = 0.07$) in sensitivity with the addition of DBT to DM (DM 87%; DBT and DM 89%) was found by Gilbert *et al.* (16,17). The investigators included 7060 subjects who underwent combined two-view DM and DBT recruited from six centers (women recalled following breast screening, and women below 50 years of age, with a family history of breast cancer).

In our study, specificity was shown to

be improved by 26% with the addition of DBT. The impact of DBT/DM on specificity as compared with DM alone was also demonstrated by Michell *et al.* which showed an improvement in specificity from 51% to 74% in a study of 738 women (14). Skaane *et al.*, in the much larger study of 24,301 cases of the Oslo Tomosynthesis Screening Trial (OTST), found that specificity was significantly higher ($p<0.001$) for DBT/DM (97.5%) compared with DM alone (96.4%) (19).

The detection and characterization of microcalcifications was better with DM. Breast tomosynthesis does not save the day in case of pathologies which have the microcalcifications as only image. The number of microcalcifications seems to be smaller on the slices; the distribution pattern and the microcalcifications morphology were characterized with difficulty on DBT and better depicted on DM. Previously published work by Tagliafico *et al.* regarding the performance of DM and DBT in characterization of microcalcification clusters using BIRADS scoring, found that sensitivity was 100% for DM and 91.1% for DBT, whereas specificity was 94.6% for DM and 100% for DBT. The authors concluded that DBT may miss a small number of cancers (20).

CONCLUSIONS

In our study, DBT significantly enhances the detection and characterization tumors in the context of mass lesions and focal asymmetric densities; the margins of the mass lesions and the inhomogeneity of the focal asymmetric densities were better evaluated on DBT then on digital mammography. Tomosynthesis isn't helpful to count or characterize the morphology and distribution of the calcifications. The microcalcifications were better characterized on digital mammography than on tomosynthesis.

PREVALENCE OF OVERWEIGHT AND OBESITY IN A RURAL POPULATION (Abstract): The main objective of this study is to estimate the prevalence of overweight and obesity in a rural population, from the north-east part of Romania. **Material and method**: The study population included 3248 adult subjects (1341 men, 1907 women), aged 18 or over, registered with their general practitioner. Anthropometric parameters were assessed by medical staff and obesity and overweight were defined according to World Health Organization's (WHO) criteria. Abdominal obesity was described according to International Diabetes Federation's (IDF) criteria. **Results**: The prevalence of overweight and obesity is 33.9% and 12.2% in men and respectively 35% and 21.3% in women. The majority of overweight and obese subjects had an increased waist circumference. There can be observed the predominance of the women in the overweight and obese group, as well as the increase of the obesity prevalence with age. **Conclusion**: Our results show that the weight excess could become a public health problem in Romania, therefore national screening programs are needed along with public information campaigns regarding effectual prevention and treatment possibilities. **Key words**: OVERWEIGHT, OBESITY, WAIST CIRCUMFERENCE

Încă din 1977, Organizaţia Mondială a Sănătăţii (OMS) a atras atenţia asupra evoluţiei statusului ponderal al populaţiei, declarând obezitatea o afecţiune cu evoluţie epidemică în întreaga lume (1). Dacă până la mijlocul anilor '70, creşterea ponderală a fost asociată cu ameliorarea stării de sănătate şi a longevităţii, în ultimele decenii se observă o schimbare a raportului risc-beneficiu, astfel încât obezitatea este recunoscută ca fiind responsabilă de creşterea morbidităţii, respectiv a mortalităţii generale şi cardiovasculare (2,3,4,5,6), devenind prioritate a politicilor de sănătate publică în întreaga lume. OMS atrage atenţia asupra necesităţii cunoaşterii dimensiunilor reale ale problemei, în condiţiile în care doar jumătate din ţările europene deţin date valide cu privire la indici antropometrici (7). În România, în absenţa unor studii epidemiologice la nivel naţional, prevalenţa supraponderii şi obezităţii a fost estimată pornind de la rezultatele unor studii efectuate în diverse teritorii. La ora actual, nu există o statistică recentă în ceea ce priveşte situaţia excesului ponderal în regiunea Moldovei (aflată în nord-estul României), ceea ce motivează realizarea acestui studiu ce are drept obiectiv principal aflarea prevalenţei supraponderii şi obezităţii într-o comunitate rurală din judeţul Iaşi.

MATERIAL ŞI METODĂ

Au fost incluse în studiu 3248 de per-

soane cu domiciliu stabil în localitatea Deleni, judeţul Iaşi, în perioada iulie 2007 - iulie 2008, cu vârsta >18 ani (reprezintă 46,07% din populaţia adultă a localităţii). S-a stabilit diagnosticul de supraponderе sau obezitate conform criteriilor OMS care apreciază statusul ponderal în funcţie de valoarea IMC (raportul dintre greutate în kg şi pătratul înălţimii în metri). Măsurarea greutăţii s-a realizat în condiţii de îmbrăcăminte uşoară şi pe nemâncate, utilizând un cântar calibrat, standardizat şi etalonat conform normelor internaţionale. Măsurarea înălţimii s-a făcut în poziţie verticală, cu subiectul descălţat, cu ajutorul unui stadiometru portabil, standardizat şi calibrat, etalonat conform normelor internaţionale. Stabilirea statusului ponderal a fost efectuată astfel : subponderal pentru IMC < 18,5 ; normoponderal pentru 18,5 ≤ IMC ≤ 24,9 ; supraponderal pentru 25 ≤ IMC ≤ 29,9 ; obezitate grad 1 pentru 30 ≤ IMC ≤ 34,9 ; obezitate grad 2 pentru 35 ≤ IMC ≤ 39,9 ; obezitate grad 3 pentru IMC ≥ 40. Circumferinţa abdominală (CA, talia) a fost măsurată la jumătatea distanţei dintre rebordul costal şi creasta iliacă, cu o bandă gradată neextensibilă. Obezitatea abdominală a fost diagnosticată la valori ale CA ≥ 80 cm la femei, şi ≥ 94 cm la bărbaţi, conform criteriilor IDF. Analiza statistică a datelor s-a efectuat cu softul *Statistical Package for Social Sciences* (*SPSS*).

REZULTATE

În populaţia studiată, doar 45% erau normoponderali, 2,9% erau subponderali iar restul de 52,1% erau supraponderali sau obezi (IMC ≥ 25 kg/m^2 conform criteriilor OMS) (tab. I).

S-a observat o prevalenţă a supraponderii de 34,5% şi a obezităţii de 17,5% (fig. 1), predominând sexul feminin în ambele grupe (prevalenţa supraponderii în rândul femeilor versus bărbaţi de 35%, respectiv 33,5%, prevalenţa obezităţii în rândul femeilor versus bărbaţi de 21,3%, respectiv 12,2%,).

În ceea ce priveşte analiza pe grupe de vârstă, s-a observat o creştere a prevalenţei excesului ponderal odată cu înaintarea în vârstă, prevalenţa maximă a supraponderii fiind pentru grupa 65-69 ani iar a obezităţii în grupa 55-59 ani (fig. 2). Grupele de

TABELUL I

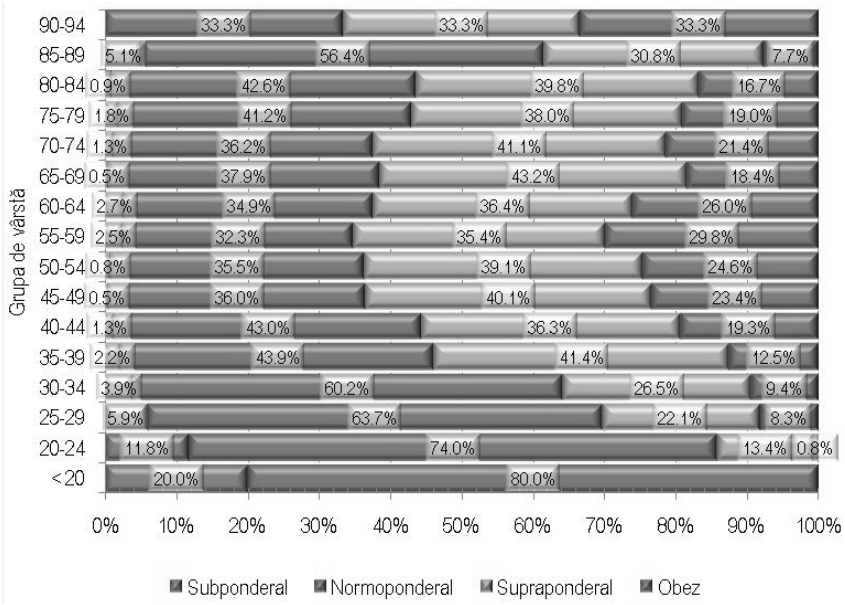

Fig. 2. Prevalenţa supraponderii şi obezităţii pe grupe de vârstă

vârstă extreme, <20 şi ≥90 ani, nu au reprezentativitate statistică deoarece sunt prea puţini pacienţi, de aceea rezultatele nu respectă trendul populaţiei.

S-a observat pentru întregul lot existenţa unei relaţii direct proporţionale între vârstă şi IMC, 5,2% din variaţia acestuia fiind explicată de variaţia vârstei ($p < 0,005$). La o creştere în vârstă cu 10 ani, media creşterilor IMC-ului este de 0,6 ($p < 0,005$) (fig. 3).

Majoritatea persoanelor cu supraponderе sau obezitate aveau şi talia (CA) crescută (tab. II, fig. 4) iar în grupul normoponderalilor (definit pe baza valorii IMC) se observă o prevalenţă crescută a prezenţei taliei mari la femei versus bărbaţi ($p < 0,001$). Acest subgrup de persoane cu IMC normal dar cu obezitate abdominală ar putea reprezenta o categorie cu risc crescut pentru afecţiuni cardio-metabolice, ştiut fiind faptul că CA reprezintă un indicator al excesului de ţesut adipos visceral.

S-a observat că 9,39% din variaţia CA (creşterea CA cu vârsta) este determinată de modificarea (creşterea) vârstei ($p < 0,001$). Putem aprecia că, în medie, la o creştere în vârstă cu 10 ani se ajunge la o creştere a circumferinţei abdominale cu 2,15 cm. Femeile prezintă o dependenţă mai puternică, în 10 ani creşterea CA este de 2,72 cm comparativ cu bărbaţii unde există o creştere a CA de 1,316 cm ($p < 0,001$) (fig. 5).

Dependenţa dintre valoarea IMC-ului şi CA este puternică, 58.3% din variaţia CA fiind explicată de variaţia IMC ($p < 0,001$) (fig. 6).

zităţii în lume. Comparaţii clare în ceea ce priveşte prevalenţa excesului ponderal în populaţii diferite sunt greu de efectuat datorită diferenţelor în ceea ce priveşte alcătuirea loturilor, criteriile de definire utilizate şi, nu în ultimul rând, metodologiei de studiu. Cu toate acestea, rezultatele studiilor şi statisticilor publicate de organizaţiile în domeniu arată că obezitatea este cel mai frecvent întâlnită în Statele Unite şi Canada, cea mai scăzută prevalenţă fiind înregistrată în China şi Japonia. În cadrul Europei, pre-

valenţa este cea mai scăzută în ţările scandinave şi cea mai crescută în ţări precum Albania, Marea Britanie, Israel (8). Rezultatele studiului nostru sunt incluse în intervalele de prevalenţă declarate de OMS în 2007 pentru Europa (7). Conform acestora, prevalenţa obezităţii este între 5,4 - 22,8% în rândul bărbaţilor (12,2% în studiul nostru) şi între 7,1 - 35,6% în rândul femeilor (21,3% în studiul nostru).

Comparativ cu datele raportate de România în 2000, observăm o prevalenţă mai mică a supraponderii în rândul bărbaţilor în studiul nostru (33,9% faţă de 38,1%) dar mai mare în rândul femeilor (35% faţă de 28,6%) (7). În ceea ce priveşte obezitatea, rezultatele noastre arată o prevalenţă mai mare atât în rândul bărbaţilor (12,2% faţă de 7,7%) cât şi în rândul femeilor (21,3% faţă de 9,5%). Aceste discrepanţe pot fi explicate, pe de o parte, de faptul că statistica României este efectuată pe o populaţie cu vârsta ≥15 ani. Pe de altă parte, studiul nostru a inclus date antropometrice măsurate de către cadrele medicale, iar datele României la OMS sunt bazate pe autoestimarea greutăţii şi taliei, importantă sursă de eroare dacă ţinem cont de faptul că adeseori supraponderalii au tendinţa de a subestima propria greutate iar înălţimea este frecvent supraestimată, indiferent de statusul ponderal (9). Rezultatele studiului nostru sunt similare cu cele obţinute în diverse localităţi urbane din România, în care prevalenţa supraponderii şi obezităţii a fost în limite destul de variabile, între 29% şi 34,6%, şi respectiv 14,6% şi 26% (10). Studiul SEPHAR efectuat în România în 2005 a arătat o prevalenţă a obezităţii în populaţia adultă de 37%, fiind mai mare în rândul femeilor, la toate categoriile de vârstă (11).

În Europa, datele cele mai apropiate de ale noastre privind prevalenţa obezităţii sunt cele raportate de Serbia şi Muntenegru în 2000 (14,3% la bărbaţi, 20,1% la femei), iar rezultate asemănătoare observăm pentru Polonia (15,7% la bărbaţi, 19,9% la femei), Bosnia şi Herţegovina (16,5% la bărbaţi, 25,2% la femei) (7). Comparând datele noastre cu alte date provenite din mediul rural, observăm o prevalenţă mai mică a obezităţii decât valoarea de 24% raportată de ţara noastră în 2003 (12).

Obezitatea (IMC ≥ 30 kg/m^2) se asociază cu o creştere a riscului cardiovascular de ~ 45% la bărbaţi şi de 30% la femei (13). Rezultatele noastre arată că la o creştere în vârstă cu 10 ani, media creşterilor IMC-ului este de 0,6 ($p < 0,005$). Studiile publicate arată că pentru fiecare creştere a IMC-ului cu 2 kg/m^2, are loc o creştere a riscului coronarian cu 23% şi a riscului de accident vascular cerebral cu 13% (14). Importantă este dispoziţia excesului de ţesut adipos, fiind demonstrată implicarea adipozităţii centrale în creşterea riscului cardiometabolic (15) dar la nivel mondial există puţine date cu privire la prevalenţa obezităţii abdominale. Grecia a raportat o prevalenţă de 54,3% în rândul bărbaţilor şi de 56,5% în rândul femeilor iar Anglia o prevalenţă de 31,1% la bărbaţi faţă de 41,1% la femei, cu specificaţia că în acest caz s-au folosit alte limite ale CA (≥ 102 cm la bărbaţi şi ≥ 88 cm la femei), şi deci datele nu pot fi comparate (7). Datele unui studiu efectuat pe o populaţie din centrul României arată o prevalenţă a obezităţii abdominale de 62,7% (52,4% în rândul femeilor şi 70% în rândul bărbaţilor) (16). În studiul nostru s-a observat un trend ascendent al valorii CA odată cu înaintarea în vârstă şi, mai mult decât atât, o relaţie de directă proporţionalitate între valorile IMC şi CA, sugerând faptul că excesul de ţesut adipos acumulat va fi depus la nivel visceral, crescând astfel riscul cardiometabolic al acestor persoane.

CONCLUZII

Prevalenţa supraponderii şi obezităţii în mediul rural din nord-estul României este

de 34,5% şi respectiv 17,5%, predominând obezitatea de gradul 1 (13,5%). Se observă o predominanţă a sexului feminin printre cei cu exces ponderal, precum şi creşterea prevalenţei obezităţii cu înaintarea în vârstă. Există o relaţie de directă proporţionalitate între indicele de masă corporală şi circumferinţa abdominală, sugerând predispoziţia depozitării excesului adipos la nivel visceral. Aceste rezultate reprezintă argumente în favoarea necesităţii dezvoltării şi implementării de programe naţionale cu scopul de a efectua screening-ul obezităţii şi tratamentul corespunzător al acesteia, de a informa populaţia cu privire la consecinţele nefaste ale excesului ponderal, alegerile alimentare sănătoase şi beneficiile activităţii fizice ca metode eficiente de prevenţie şi tratament.

THE ROLE OF OXIDATIVE STRESS ON PERINATAL PATHOLOGY (Abstract): Normally, oxygen is a vital gas that allows the body's cells to function by producing mitochondrial ATP. Despite its essential physiological role, molecular oxygen is a toxic potential in the body. In extreme cases, breathing with high oxygen concentrations leads to hyperoxia, which causes CNS, lung, renal, hepatic and ocular toxicity due to membrane and other cellular disruption. Effects on cells are supposed to be associated with oxidative stress and are mediated by ROS. In placental mammals, the placenta is a transient organ, with a very important function - to manage the nutrient, oxygen and waste exchanges between the mother and the fetus. An additional level of complexity is that in humans, a hypoxic state must be maintained in the first trimester, while later, the oxygen pressure rises to that of normal tissue conditions. This implies that a very strict control of oxygen pressures must be maintained in the placenta, and this process, involving thousands of genes and numerous steps, allows for multiple possibilities of error. These dysfunctions become either the causes or consequences of placental diseases such as IUGR, spontaneous premature birth, gestational diabetes and, most importantly, preeclampsia. In the cascade of events leading to eclampsia, HELLP syndrome, premature birth or other consequences on mother and child, placental oxidative stress is placed in a very high position, even under placental ischemia due to deficient spiral artery remodeling. A deeper understanding of the mechanisms governing oxidative stress in both placenta and maternal vascular endothelium is likely to provide new opportunities for the development of innovative therapeutic approaches to prevent IUGR, improving the future quality of life for newborns. **Keywords:** OXIDATIVE STRESS, PERINATAL PATHOLOGY, INTRAUTERINE GROWTH RESTRICTION.

Oxygen has both benefits and adverse effects that are potentially harmful for biological systems. The main role of this element is to participate in the generation of adenosine-5-triphosphate (ATP), thus sustaining the energy and life of complex, multicellular organisms (1).

Faced with a constant oxidative attack from reactive oxygen species (ROS) the human body has developed a complex antioxidant defense system that generally maintains oxidation in balance. However, occasionally, this balance can be disturbed, resulting in oxidative stress. Due to the multiple and various effects that oxygen toxicity can has on cells, oxidative stress is best defined in general terms as a change in the pro-oxidant-antioxidant balance in favor of the former. Oxidative stress is now recognized to play a central role in the pathophysiology of many disorders, including complications of pregnancy (2).

The concept of pro-oxidant-antioxidant balance is essential for an understanding of oxidative stress for several reasons. Firstly, it underlines the fact that disturbance can be caused by changes on both sides of the balance (e.g. abnormally high ROS generation or antioxidant defense defects). Secondly, it highlights the homeostatic concentrations of ROS. Although ROS have first come into the attention of biologists as potentially harmful byproducts of aerobic metabolism, it is now recognized that they play an important role as secondary messengers in many intracellular signaling pathways (3). Finally, the concept of balance draws attention to the fact that there will be a gradual response to oxidative stress. Therefore, minor balancing disorders can lead to homeostatic adaptations in response to changes in the environment, while major perturbations can lead to irremediable lesions and cell death (2).

The developing embryo and fetus are very susceptible to the adverse effects of the oxidative stress, both initiated by the endogenous processes and given by xenobiotics that increase ROS formation. Susceptibility is given on the one hand by the relatively high levels of embryonic and fetal enzymes involved in ROS formation and xenobiotic bioactivation to free radical intermediates and, on the other hand, by low levels of protective antioxidant enzymes. Effects on the embryo/fetus are due in part to the high rates of cell division and differentiation and the complex processes involved in the formation of organs. Changes in these processes may result in in utero or perinatal death or structural and functional birth defects, also known as teratogenesis. The instability of ROS, especially of hydroxyl radicals means the formation, first of all, of ROS in the product of conception side, rather than on the mother's side; this plays a critical role in teratogenesis.

Oxidative stress

1. Overview

Oxidative stress (OS) is defined as "an imbalance between oxidants and antioxidants, leading to an interruption of signaling and redox control and/or molecular deterioration"(4). OS involves ROS, the most frequent ones being superoxide ($O2^{\bullet -}$), hydrogen peroxide (H_2O_2) and hydroxyl radical (•HO).

A parallel process is known as nitrosative stress (NS), which is defined as an imbalance in the ratio of nitrosant agents with antioxidants. NS mainly involves the nitrogen oxide (•NO) and peroxynitrite ($ONOO^-$) species of reactive nitrogen (RNS).

In aerobic organisms, controlled yield of ROS and RNS is a physiological phenomenon that plays a fundamental role in the metabolism and cascade of cellular signaling. OS and NS occur when there is an imbalance between the formation of oxidizing substances and the antioxidant molecules that realize their detoxification. Because of their highly reactive properties, ROS and RNS can cause structural and physiological lesions of DNA, RNA, proteins and lipids, including cell membrane-bound lipids (5).

ROS and RNS are produced in different cellular compartments or metabolic pathways (6):

- Mitochondria, endoplasmic reticulum (ER) and nuclear membrane produce superoxide anions due to autooxidation of the components of the electron transport chain.
- ROS are also produced as a consequence of acidic metabolism and cytochrome P_{450}.
- Nicotine-amide dinucleotide phosphate oxidases are still an important source of ROS. They generate superoxide anion by transferring electrons inside the cell through the membrane and by reducing molecular oxygen.
- NO synthase can generate superoxide

and hydrogen peroxide, especially when concentrations of its substrate, l-arginine or its cofactor, tetrahydrobiopterin are low.

2. Reactive oxygen species

As mentioned above, there are several reactive oxygen species (ROS). This term applies to both free radicals and their non-radical intermediates. Free radicals are defined as species containing one or more non-participant electrons, and this incomplete electronic coating gives them their high reactivity. Free radicals can be generated from several elements, but the most important biological systems are those that involve oxygen and nitrogen.

In physiological conditions, the most frequently generated free radical is the superoxide anion, and the mitochondria are considered the main source for it (7).

In addition, superoxide anion can also be generated by leaking electrons from the shorter electron transport chain within the endoplasmic reticulum (8). Formation of disulfide bonds during protein folding is an oxidizing process and approximately 25% of superoxide is formed in this way in the endoplasmic reticulum. This process increases in cells with high secretion and also under stress of the endoplasmic reticulum when repeated folding attempts of wrong folded proteins can occur.

Other sources of superoxide under physiological conditions include nicotinamide-adenine-dinucleotide phosphate (NADPH) oxidase enzymes (which generate substantial amounts during pregnancy but especially at the beginning of pregnancy) (9), cytochrome P_{450} and other oxido-reductases. Therefore, various growth factors, drugs and toxins may increase the generation of ROS (2).

Superoxide is detoxified by superoxide-dismutase enzyme, that converts it into hydrogen peroxide. Hydrogen peroxide is not a free radical, so it is less reactive than superoxide. However, it falls under the term ROS as it is inherently involved in the generation and detoxification of free radicals. Because it is nonpolarized, it is capable of diffusing through cellular and organelle membranes and therefore acts widely as a secondary messenger in signal transduction pathways. Hydrogen peroxide is, in turn, detoxified to water by the enzymes catalase and glutathione-peroxidase.

It is important that antioxidant enzymes act in a conjoined manner, because an imbalance in superoxide and hydrogen peroxide concentrations can lead to the formation of the more dangerous hydroxyl ion. This reaction is catalyzed by free ferrous ions during the Fenton reaction. The hydroxyl ion has an estimated life span of 10^{-9} seconds and reacts with any biological molecule in its immediate vicinity in a diffusion-limited manner. Because it is so strongly reactive, there is no known hydroxyl ion capture agent.

Increased superoxide generation can also lead to interactions with nitric oxide to form peroxynitrite. Peroxynitrite is a potent pro-oxidant and, because it is capable of diffusing up to 5 μm, can affect neighboring cells (6).

3. Antioxidant factors

The oxidant effect is inhibited by enzymatic and non-enzymatic protection factors.

a. The enzymatic pathway

Enzymatic protection factors are based on a transition metal capable of taking on different valences in electron transfer during the detoxification process. Two isoforms of superoxide dismutase convert superoxide to hydrogen peroxide. This is then decomposed into water through the action of catalase or glutathione peroxidase, a tetrameric selenoprotein. Glutathione is the major redox buffer in cells and is synthesized in cytosol from 1-glutamate, 1-cysteine and glycine (10).

b. The non-enzymatic pathway

Non-enzymatic oxidoreduction systems

include ascorbic acid (vitamin C) and α-tocopherol (vitamin E). They act in conjunction, the ascorbate being necessary for the regeneration of reduced α-tocopherol. In addition, thiol compounds, such as thioredoxin, are capable of detoxifying hydrogen peroxide, but in turn require conversion back into reduced form by thioredoxin reductase.

Ceruloplasmin and transferrin also play important roles by sequestering free iron ions and thus inhibiting Fenton's reaction and hydroxyl radical production (2).

Polymorphisms of antioxidant enzymes (10, 11) or dietary restrictions of micronutrients such as selenium can thus play an important role in the predisposition to oxidative stress and complications of pregnancy (12).

Biologic effects of reactive oxygen species

1. Activation of transcription factors sensitive to the redox reaction

Activation of redox-sensitive transcription factors, such as AP-1, p53 and NF-κB, regulates the expression of proinflammatory cytokines and other cytokines, cell differentiation and apoptosis. Under normal conditions, NF-κB is kept inactive by binding to the IκB inhibitory subunit. However, under stress conditions, IκB becomes phosphorylated and dissociates from NF-κB, which then translocates to the nucleus and activates expression of proinflammatory cytokines and other cytokines (2).

2. Activation of protein-kinases

By activation of protein kinases, cells respond to a variety of extracellular signals and stress through a family of mitogen-activated protein kinases (MAPK). From this family, ROS-induced activation of extracellular regulated kinases generally promotes cell survival and proliferation, while p38-MAPK stimulation and SAPK-JNK kinases induce apoptosis. p38 and SAPK-JNK are activated by phosphorylation by an upstream kinase, apoptosis 1 kinase signal (ASK1). Under normal conditions, ASK1 is kept inactive by binding to thioredoxin, but superoxide is able to oxidize thiol groups in the latter, leading to a conformational change and its release (2).

3. Opening of ionic channels

ROS imbalances lead to the loss of intracellular calcium homeostasis, with the release of calcium ions from the endoplasmic reticulum and other forms of storage. Calcium concentration in the lumen of the endoplasmic reticulum is much higher than in the cytosol. ROS are able to activate the calcium-releasing channels in the endoplasmic reticulum membrane, including the inositol-1,4,5 triphosphate receptor (IP3R) and the ryanodine receptor (13). The result is calcium release from the endoplasmic reticulum, which will activate various calcium-sensitive processes inside the cell including many of the above-mentioned signaling pathways (14). The increase in concentration of calcium ions in the cytosol will adversely affect mitochondrial function, with high ROS production within the cell. As a result, the potential of the mitochondrial membrane and ATP synthesis collapse. If mitochondria are affected throughout the whole cell, ATP concentrations decrease, ionic homeostasis is lost, and cell necrosis occurs (2).

4. Lipid peroxidation

Hydroxyl radicals are able to cause lipid peroxidation in the cell membrane or any organelle containing large amounts of polyunsaturated fatty acid side chains. By extracting hydrogen from the hydrocarbon side chain of a fatty acid, these radicals create a carbon-based radical. If oxygen is present, it can react to form a peroxyl radical, which in turn is able to absorb hydrogen from an adjacent fatty acid, thus propagating the

reaction.

Because vitamin E is liposoluble and possesses a hydrophobic tail, it tends to accumulate inside the lipid membrane. Here, it is the most important breaker of the above-mentioned chain reaction, because it reacts with the lipid peroxidic radicals about four times faster than they can react with the adjacent fatty acid side chains (2).

5. Protein modifications

Amino acids, both free and in proteins, are a target for oxidative lesions. Direct oxidation of the side chains leads to the formation of carbonyl groups (aldehydes and ketones), and proline, arginine, lysine and threonine are particularly vulnerable to attack (15).

At physiological levels, it is believed that protein nitration is a selective and reversible process that leads to activation in a manner similar to phosphorylation, but at higher levels it can be detrimental. Nitration in the placenta may have different effects, both with gain and loss of function (16).

6. DNA oxidation

DNA is primarily attacked by hydroxyl radicals and a variety of products can be generated by reactions with either DNA bases, or with deoxyribose.

Attacks on sugars can cause chain breakage, while those on histone proteins can lead to cross-links that interfere with chromatin folding, DNA repair, and transcription. Consequently, the aberrant mutation or expression of genes may occur.

Mitochondrial DNA is extremely vulnerable to the attack of ROS due to its proximity to the site of generation of superoxide in the electron transport chain, lack of the protection of histones and minimum repair mechanisms that exist at this level. Consequently, mitochondrial DNA damage is important even under normal conditions, and mutations occur at a frequency of five to ten times greater than that observed in the nucleus (17). Since mitochondrial DNA encodes several proteins, including electron transport enzymes, mutations can lead to decreased energy production and the risk of additional electron loss, exacerbating initial stress.

Effects of oxidative stress on the maternal-fetal interface

Oxidative stress occurs at the maternal-fetal interface at the beginning of pregnancy. It plays a role both in the normal development of the placenta and in the pathophysiology of complications such as spontaneous abortion, preeclampsia, intrauterine growth restriction (IUGR) and premature rupture of membranes (18).

1. Types of placental cells and the origin of oxidative stress at this level

The human placenta is composed of numerous cell types, as shown recently by the sequencing performed by Tsang *et al.*, which showed twelve major cell groups identified through their expressed profile (19). Among these, the most abundant are stromal cells, endothelial cells, the villous cytotrophoblast, and extravillous trophoblast. In addition, syncytiotrophoblast resulting from fusion of syncytiotrophoblastic cells was clearly separated from other trophoblastic cell lines.

Oxidative stress can be induced by a low oxygen partial pressure, hyperoxia, or alternation of hypoxia and reoxygenation, as seen in various very vascularized tissues such as brain or eye (20). In addition, there have been identified immune cell groups (Macrophages, dendritic cells, T cells), which may also be responsible for generating oxidative stress.

In normal placenta, hypoxia is a physiological element, detectable in the first trimester, as demonstrated through in vivo methods (21). This naturally occurring phenomenon renders unclear the distinction

between common physiological phenomenon and the possible harmful effects of hypoxia at certain stages of placental development.

In addition to trophoblastic cells, oxidative stress can come from endothelial cells present in placental tissue, stromal cells of cells, or immune cells (Hofbauer cells). Generally, trophoblastic cells undergo changes in gene expression due to oxidative stress. This event, occurring in the placenta, generates extracellular vesicles that are released into the maternal circulation and will influence gene expression in both maternal immune and endothelial cells. These extracellular vesicles are exosomes, measuring 30-100 nm and micro-vesicles of 100-1,000 nm. Also, larger cellular debris is released from the placenta, which includes nuclear aggregates and apoptotic bodies (20-500 μm and 1-4 μm, respectively) (5).

2. Oxidative stress and placental remodeling

The human placenta is unique because the villi are initially formed on the entire surface of the chorionic sac. However, from with the end of the first trimester, villi on the superficial side regress to leave the definitive, discoid placenta. Oxidative stress is currently recognized to play a central role in this process, thus this regression, occurring in all pregnancies, can be considered physiological.

The general perception of the intrauterine environment in early pregnancy has undergone significant changes over the past two decades. It is now accepted that placental development occurs in a relatively low concentration of oxygen, maintained by secretions in the endometrial glands, rather than by the maternal circulation (22). It has been speculated that this environment protects the embryo during the development from the teratogenesis mediated by free oxygen radicals (23). The maternal arterial blood flow is prevented from entering the placental intervillous space by extracellular cytotrophoblast cell plugs that invade the uterine spiral arteries, as part of the physiological transformation process (24). Intraplacental maternal circulation is fully established by the end of the first trimester, when the abovementioned plugs are displaced by a mechanism that is currently unknown. The ultrasound evidence has shown that the circulation begins preferentially at the periphery of the placenta, where the trophoblastic invasion is the least extensive and progressively extends to the central region (25).

The onset of placental circulation is associated with a threefold increase in placental oxygen concentration (26). This will mean increasing ROS generation rates, especially in the syncytiotrophoblastic critical layer, which contains antioxidant enzyme defense factors, copper or zinc superoxide dismutase and catalase (27, 28). As a result, specimens collected from the peripheral region of the placenta contain high levels of chaperon HSP70 protein, nitrotirozine residues indicating peroxynitrite formation and morphological evidence of degenerative changes in syncytiotrophoblast compared to those in the central region (25). Molecular evidence confirms the activation of the apoptotic cascade in peripheral villi and, over an extended period, this would be sufficient to lead to their regression.

3. Oxidative stress in intrauterine growth restriction

Intrauterine growth restriction (IUGR) may have various causes, such as maternal malnutrition, excessive alcohol consumption, smoking, and also glucocorticoid treatment. This is often observed with comorbidities such as preeclampsia and gestational diabetes. In humans, IUGR is associated with increased oxidative stress in the placenta (29, 30).

Although IUGR can have many causes, most cases that have no genetic or infectious cause are thought to occur by compromising maternal placental circulation. This conclusion is based on the common association with high-strength uterine artery waves, but also on previous morphological studies of the spiral arteries. Studies have reported a poor physiological conversion of the arteries as in preeclampsia, but to a lesser extent, especially in the intramiometric segment (31). Of course, some studies note a positive correlation between birth weight and conversion rate (32).

Unlike preeclampsia, surprisingly little attention was paid to the role of placental oxidative stress in standalone IUGR cases. The low available evidence indicates that the level of oxidative stress is either similar to normal or intermediate between a normal control and an early-onset pre-eclamptic placenta (33). These findings are consistent with the vascular insults presented above.

However, morphological and molecular evidence of endoplasmic reticulum stress is observed in the placenta of these patients (34). The level of stress is lower than in preeclampsia without any evidence of apoptotic cascade activation, but it is sufficient to induce phosphorylation of IF2α and suppression of protein synthesis with a reduction in cyclin D1 level.

Consequently, it is speculated that the low chronic stress of the endoplasmic reticulum may occur from the onset of maternal circulation and lead to a lower growth of the placenta. This is consistent with the low development of the placenta observed with serial ultrasound scans in these cases (35).

In rodent models, the different etiologies of IUGR led to oxidative stress in the placenta, confirming that oxidative stress is highly relevant in the pathophysiology of this disease. In mice, when IUGR is induced by ischemia-reperfusion cycles of the placenta (temporary occlusion of uterine arteries), the oxidative stress-induced DNA lesion is present (36). In a dexamethasone induced IUGR model, no difference was detected in the classical oxidative stress pathways, but a strong increase in antioxidant enzyme activity was observed, meaning that the placenta adapted to its pro-oxidant conditions (34).

COLON MICROBIOTA AND CARCINOGENESIS

A study published by Bundgaard-Nielsen C, *et al.* investigated the association between colon microbiota and the outcome and carcinogenesis of colorectal cancer. qPCR technique was used to detect the presence and load of bacteria directly in colon tissue samples from patients diagnosed with colorectal cancer, adenomas, or diverticular disease. qPCR was set to detect *Streptococcus gallolyticus, Fusobacterium nucleatum,* and *Bacteroides fragilis*. The bacterial microbiota was then compared to prognosis. The results did not support the role of these bacteria during colorectal beginning, since they showed the absence of *S. gallolyticus* from all tested tissue samples, while *F. nucleatum and B. fragilis* were equally distributed in tumors and normal tissue. However, *F. nucleatum* and *B. fragilis* were less present in adenomas. The study also revealed that *F. nucleatum and B. fragilis* status did not influence the five-year prognosis of the patients. When 16S rRNA gene sequencing was performed, it found an association between *Prevotella* and the presence of tumors, as well as an association between *Acinetobacter* and adenomas or diverticula (Bundgaard-Nielsen C, Baandrup UT, Nielsen LP, Sørensen S. The presence of bacteria varies between colorectal adenocarcinomas, precursor lesions and non-malignant tissue. *BMC Cancer* 2019; 19(1): 399. doi: 10.1186/s12885-019-5571-y.).

EPIDERMOID CYST OF THE SPLEEN

EPIDERMOID CYST OF THE SPLEEN (Abstract): Epidermoid cyst of the spleen are rare benign formations within the splenic tissue. They are mostly discovered incidentally because they have minimal symptomatology to none. This kind of cyst is difficult to diagnose despite the advanced imaging investigations and only the histological examination can determine a epidermoid cyst. We present the case of a 21-year-old man who presented with vague left lumbar discomfort after intense physical effort and was found to have a large splenic mass with cystic components. Patient underwent a classical splenectomy and had an uneventful recovery with histopathology revealing an epidermoid splenic cyst. **Conclusions:** Epidermoid splenic cysts are difficult to diagnose and differentiate with imaging alone. They have a variable presentation and can present like as a cystic mass. It is important to include them in the differential diagnosis of splenic masses since histopathology is the final determinant of the diagnosis. **Keywords:** EPIDERMOID, CYST, SPLEEN.

Epidermoid cyst of the spleen is a very rare form of splenic mass. They are classified into true cyst (primary-composed of fibrous tissues, 25%) and pseudocyst (secondary, 75%), according to the presence of an epithelial cellular lining inside the cyst. Splenic epidermoid cyst, a true cyst, constitutes approximately 10% of benign, nonparasitic cysts and is more commonly encountered in individuals under 40 years old and in females (1). The most common symptoms are nonspecific such as left upper abdominal mass, followed by left upper abdominal pain and epigastric pain. Few patients may present with complication, such as infection, rupture, and bleeding (2). A surgical treatment is recommended for symptomatic cysts larger than 5 cm (3).

CASE PRESENTATION

A 21-year-old male presented in our department with complaints of dull pain and discomfort in the left lumbar area, which had been present in the last month. Pain was intermittent in nature, which had increased in intensity since past 15 days. There was no history of fever, trauma and there was no association with food intake. On physical examination, a firm, smooth, slightly tender mass was seen in left hypochondrium, which was palpable.

Ultrasonography of abdomen was done,

and it showed enlarged spleen 150/93 mm, with well-defined inhomogeneous cystic mass, which measured 84/74/82 mm in size, 65 cm^2 with internal calcifications (fig.1).

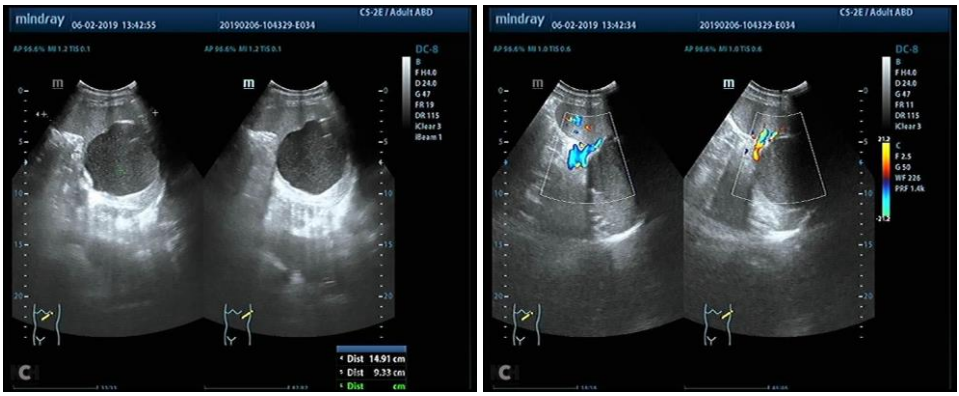

Fig. 1. Ultrasonography of abdomen

Computed Tomography of abdomen was performed after administration of intravenous contrast. The scan showed enlarged spleen, with the bipolar diameter about 130 mm, and a large well-defined cystic mass in the medial segment, intra-parenchymal, which was 91/73/63 mm in size, (fig. 2), with thin septum in the downside and calcifications.

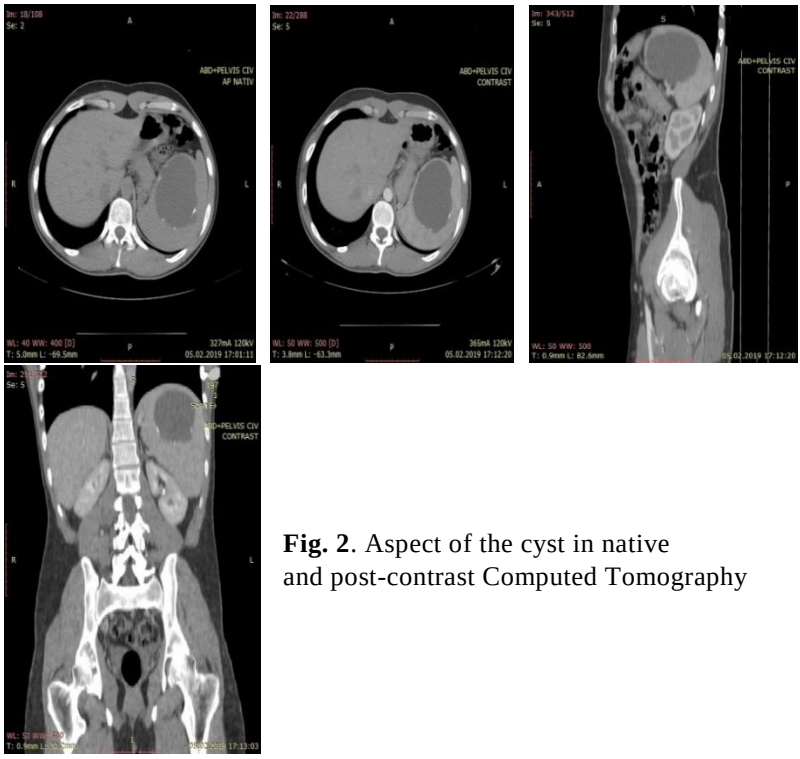

Fig. 2. Aspect of the cyst in native and post-contrast Computed Tomography

Elective laparotomy was performed, and a large splenic cyst was found, which was located at the middle part of the spleen. Due to location and size of cyst, preservation of the spleen was considered as impossible and splenectomy was done. Grossly, large sized cystic lesion which was approximately 100 of maximal diameter was discovered, with almost total replacement of splenic tissue at one side (fig. 3).

Fig. 3. The spleen of 12.5/11.0/6.5 cm with the cyst 7.5 / 4.7 cm

After the section of the spleen, the macroscopic examination revealed two cystic formation was found of 8.4/7.0/4.8 cm and 2.1/1.6/1.4 cm with irregular internal conformation, and calcifications .

Histopathological, microscopic examination revealed that the wall was formed on the internal side from squamous epithelium without keratin function , with large areas of ulcerations and macrophage adherence. Underneath the epithelium was sclerahyalinosis and calcifications (fig. 4). The diagnosis of splenic epidermoid cysts was confirmed. The post-operative clinical course of the patient was satisfactory and uneventful.

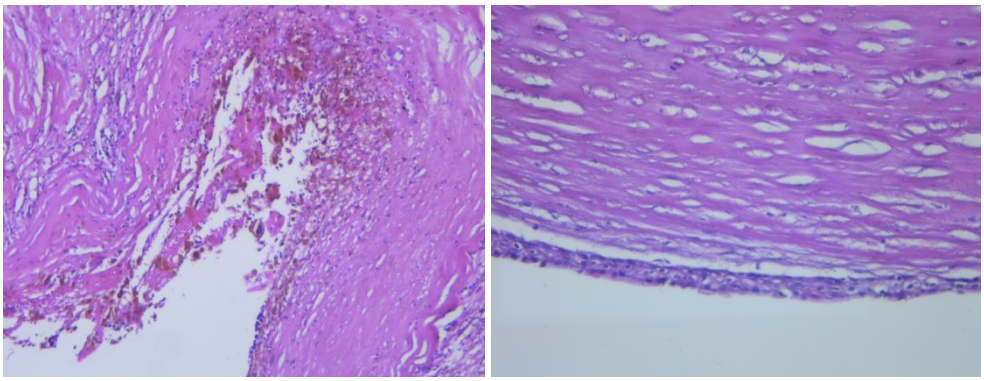

Fig. 4. Histopathological aspect of the epithelium.

DISCUSSION

The first case of epidermoid cyst was reported by Andral, in 1829, that was found at autopsy (4). In 1867 J. Pean performed

the first successful splenectomy for a splenic cyst (5). After that 12 isolated case were reported in the literature. In 1940 Fowler published a collective review of 137 cases of splenic cysts and made an update in 1953 to include 265 cases of nonparasitic splenic cysts (6, 7).

Since the first case was reported in 1829 by Andral many pathophysiological hypotheses have been proposed, the main one being enfolding or entrapment of peritoneal mesothelial cells in the splenic parenchyma during embryogenesis in the intrauterine life (mesothelial invagination theory, endodermal inclusion theory) (8). Splenic cysts are classified worldwide according to Martin's criteria: type 1 are true cysts with a lining epithelium, while type 2 are false cysts without a defined lining epithelium. The first group includes both nonparasitic and parasitic cysts, the latter ones being most frequently caused by *Echinococcus granulosus*. Type 1 nonparasitic cysts have been further divided into congenital (epidermoid, dermoid) and neoplasic (hemangiomas, lymphangiomas) cysts, among which hemangiomas and dermoid cysts are the most and least common, respectively. The second group includes the so-called pseudo-cysts which are usually related to trauma, hemorrhage, abscess, and infarction, and occur much more frequently than epithelium-lined true cyst (9).

Epidermoid cysts are the rare, only 10% of benign, nonparasitic cysts of the spleen(10). True cysts and false cysts cannot be differentiated on imaging explorations; false cysts have thicker fibrous walls and calcifications, along with internal debris. On ultrasonography epidermoid cysts are described as well-defined, with a thin wall, anechoic cystic lesions. There can be increased echogenicity caused by intracystic hemorrhage and cholesterol crystals and inflammatory necrotic debris which are same as those which are seen in false cysts. Although peripheral calcifications occur more frequently in post-traumatic or false cysts, in epidermoid cysts with occasional internal septations, cystic walls may show curvilinear or plaque like calcifications. In addition, computed tomography may give clearer picture regarding intracystic fluid, internal septations or calcifications (11).

Although partial splenectomy offers a definite solution in case of splenic cysts (< 5 cm), conservative treatment like aspiration alone, incision and drainage can also be considered. But total splenectomy is the treatment of choice in case of larger cysts (> 5cm), as it prevents serious complications like rupture, hemorrhage, infection and sometimes, the recurrence which is attributed to coexistence of invisible tiny cysts that had remained in the splenic tissue after the dissection of the major cyst. In the cases where hilum is involved, splenectomy remains a relatively safe procedure (12).

Since it was showed before that the response to this disorder can vary depending on multiple factors (13), described above, we can also connect the present aspects with the previous works of our group (14-17) in the multifactorial approach (e.g. related to inflammation and oxidative stress, social influence, pain perception or drug development substrate) for the management and treatment of this specific epidermoid cyst of the spleen.

Radiologically distinguishing between true and false splenic cysts does not seem to be possible preoperatively and the final diagnosis relies on histopathological examinations of wall of the cyst. However, total splenectomy (open or laparoscopic) is primarily recommended for the prevention of

complications which are seen as infections, hemorrhage and rupture.

CONCLUSIONS

Patients with splenic cysts are usually asymptomatic, who present occasionally with vague symptomatic presentations. Discovery of cystic lesions of spleen is an easy task which can be achieved by doing imaging studies, but determination of true nature and pathology of the cyst is not possible all the times preoperatively. Although, nowadays emphasis is being laid on spleen preserving surgeries, it has been observed that conservative treatment is not possible in the cases where cysts are of large sizes and where the chances of surgical complications are higher than the rare risk of overwhelming post-splenectomy sepsis. The ultimate diagnosis, however, depends upon histopathological findings.

Generally, the tumor size correlates with clinical presentation and small cysts are asymptomatic, but large lesions of the spleen tend to present symptoms related to bulky size, such as left upper abdominal pain, upper abdominal mass, and epigastric pain and fullness.

In our case, the patient presented the most common clinical findings left lumbar pain, and hematological and biochemical investigations were within normal limits. Accurate clinical diagnosis of primary epithelial cysts is difficult. The differential diagnoses for a cyst in the spleen include parasitic echinococcal disease, congenital cyst, posttraumatic pseudocysts, infraction, infection, pyogenic splenic abscess, metastatic disease, and cystic neoplasm. The instrumental investigations are important to complete the diagnosis. It is possible to employ ultrasonography, magnetic resonance, and computerized tomography. Ultrasonography could differentiate solid and cystic lesions, identify calcifications, and recognize some intra-cystic septa or irregular walls. We used CT scan to complete the diagnosis and to have information in regard to the morphology of the cyst, the nature of fluid and the exact location and its relationship with adjacent structures. At the same time, we affirm that radiologically distinguishing between true and false splenic cysts do not seem to be certain preoperatively and the final diagnosis relies on the histopathological examinations.

Because the spleen had a large size, we preferred to perform a classic laparotomy and the size and position in the middle of the spleen dictated the total splenectomy.

AUTOPHAGY IN ALZHEIMER'S DISEASE AND PROMISING MODULATORY EFFECTS OF HERBAL MEDICINE

Alzheimer's disease (AD) is a progressive and unremitting neurodegenerative disorder characterized by memory loss and cognitive impairment. It affects the quality of life of victims severely. The prevalence of AD has been increasing in recent years. Therefore, it is of great importance to elucidate the pathogenesis of AD and find out effective therapeutic approaches. Autophagy, a primary intracellular way of degrading aggregated proteins and damaged organelles, has been discovered to be involved in the pathological changes of AD. In the last few years, much progress has been made in finding autophagy regulators from natural products, providing new insights to develop treatment strategy for AD by targeting autophagy. In the present review, we provided an overview of the recent research progress regarding the function role of autophagy in AD, the regulation mechanisms of autophagy-lysosomal pathway as well as therapeutic potential of herbal medicine on AD by targeting autophagy. Modern pharmacological research uncovers that some active components from herbal medicine exert curative effect against AD through various mechanisms including cholinesterase inhibition activity, neuroprotective effect via anti-oxidation, anti-apoptosis and anti-neuroinflammation, neurogenic activity, as well as modulation of Aβ and p-tau metabolism by targeting autophagy. Recently, more and more natural products are attracting attention to identify autophagy regulators. A large number of studies confirm that the active compounds regulating autophagy process contain saponins, alkaloids, flavonoids, polyphenols and other structures, which provide alternative therapies for neurodegenerative diseases in vitro and in vivo (Qiang Zenga *et al*. Autophagy in Alzheimer's disease and promising modulatory effects of herbal medicine. *Experimental Gerontology* 2019; 119: 100-110).

DRUG RESISTANT EPILEPSY DUE TO BILATERAL PERIVENTRICULAR NODULAR HETEROTOPIA. CASE REPORT

DRUG RESISTANT EPILEPSY DUE TO BILATERAL PERIVENTRICULAR NODULAR HETEROTOPIA. CASE REPORT (Abstract): Periventricular nodular heterotopia (PNH) is among the most frequent malformations of cortical development due to disturbance in neuronal migration and is associated with intractable epilepsy. Neuronal migration disorders cause severe syndromes, including refractory epilepsy and major psychomotor development disorders. It has been demonstrating that approximately 80% of familial cases of PNH are related to FLNA mutation, gene located on the long arm of the X-chromosome inherited in a dominant fashion. A constellation of syndromes, including heterotopic nodules with intractable epilepsy, microcephaly, and severe develop-mental delay is seen in ARFGEF2 mutations, a gene located in chromosome 20 with an autosomal recessive inheritance pattern. We present a case of 18-years old patient, right-handed, without remarkable findings in personal history of childhood, with normal social and psychiatric development. At the age of 15 she was admitted in the department of Psychiatry for depression and behavioral disorder (irritability and aggressive behavior) and she was treated with selective serotonin reuptake inhibitors (this happens frequently showed a small study which revealed that EEG can be abnormal in patients with neurotic disorders. **Keywords:** PERIVENTRICULAR NODULAR HETEROTOPIA, EPILEPSY, DRUG.

Periventricular nodular heterotopia (PNH) is among the most frequent malformation of cortical development, due to disturbance in neuronal migration and is associated with intractable epilepsy.

Neuronal migration disorders cause severe syndromes, including refractory epilepsy and major psychomotor development disorders. Several of these disorders are caused by mutations in genes encoding cytoskeleton proteins.

PNH correspond to a groups of neuronal cells that didn't migrate, remaining in the subependymal region (periventricular heterotopia) or have stopped from migration, in their way towards the cortex surface (subcortical heterotopia). During first trimester of gestation, post mitotic neurons migrate along the scaffold of radial glia, to form the multi-layered cortex (1).

The prevalence of PNH in the general population is unknown, although some reports suggest that it represents 15-20% of the various forms of cortical malformations. It has been demonstrating that approximately 80% of familial cases of PNH are related to FLNA mutation, gene located on the long arm of the X-chromosome, inherited in a

dominant fashion. Heterozygous mutation in females with bilateral and symmetrical PNH is usually associated with normal intellect, with or without epilepsy. Mutations in males are thought to be lethal, usually with intrauterine death (2).

FLNA is a cytoskeleton molecule, that plays an important role in the initiation and progression of neuronal movement, in the process of migration, possibly by maintaining these cells attached to supporting cells, until they receive the signal for locomotion (2).

A constellation of syndromes, including heterotopic nodules with intractable epilepsy, microcephaly and severe developmental delay, is found in ARFGEF2 mutations, a gene located on chromosome 20, with an autosomal recessive inheritance pattern, that encodes a protein BIG2, localized along the Golgi system and recycling endosomes (3).

Other genes implicated in this disease are C6orf70 (6q27), that encodes ERMARD protein and is responsible for bilateral PNH, FAT4 (4q28.1), which codes FAT atypical cadherin 4 and DCHS1 (11p15.4) with Dachsous cadherin-related 1 protein, responsible for posterior PNH (3).

PNH has also been associated with duplication 5p15, deletion 6q26-q27 or 7q11.33, fragile X syndrome, Williams syndrome, 22q11 microdeletion syndrome and 6q terminal deletion syndrome, demonstrating that PNH is a genetically heterogeneous disorder (2).

There are complex interactions between PNH and allo- or neocortex , which shows that PNH is part of a network, implicated in epileptogenesis and higher cortical functions. Interictal spiking activity was found in ectopic grey matter, in the cortex overlying the nodules and in the mesial temporal structures (4, 5, 6).

Tractography and functional MRI (fMRI) studies have suggested anatomic and functional connections between heterotopic nodules and overlying cortex, as well as connections between nodules and regions of contralateral cortex, other heterotopic nodules and ipsilateral cortex (3).

CASE REPORT

We present a case of 18-years old patient, right-handed, without remarkable findings in personal history of childhood, with normal social and psychiatric development. At the age of 15, she was admitted in the department of Psychiatry for depression and behavioral disorder (irritability and aggressive behavior) and she was treated with selective serotonin reuptake inhibitors. A year later, she was admitted in the department of Neurology for recurrent seizures, manifested with rising epigastric sensation, visual hallucinations, associated with cognitive seizures such as déjà vu and oral automatisms. Despite the association of two antiepileptic drugs (Levetiracetam 2,000 mg/day and Carbamazepine 800 mg/day), the frequency of seizures remained high (1-2 seizures/ week).

The MRI with high resolution revealed hyperintense T2 and hypointense T1 bilateral bands located adjacent to the temporo-occipital horn of the lateral ventricle, with the same signal as the cortex. PET-CT scan showed left mesial temporal lobe hypometabolism (fig. 1, 2).

The patient underwent prolonged video-EEG monitoring, that detected interictal epileptiform discharges, such as sharp waves, spike-wave complexes and polispike-waves in left posterior temporal and basal-temporal region, with phase reversing over T6. There have also been recorded multiple seizures, manifested clinically with epigastric aura, speech arrest, oral automatisms, hyper motor behavior, with a duration of approximately three minutes. During the seizure, she was unresponsive, unable to carry out simple com-

mands and she had no recollection of the seizure. EEG showed a teta rhythm of 5 Hz, with low amplitude, started initially in FB1, then in T3 and T5, followed by ictal rhythm observed in FB1 and T3, with rapidly bilateral propagation (fig. 3).

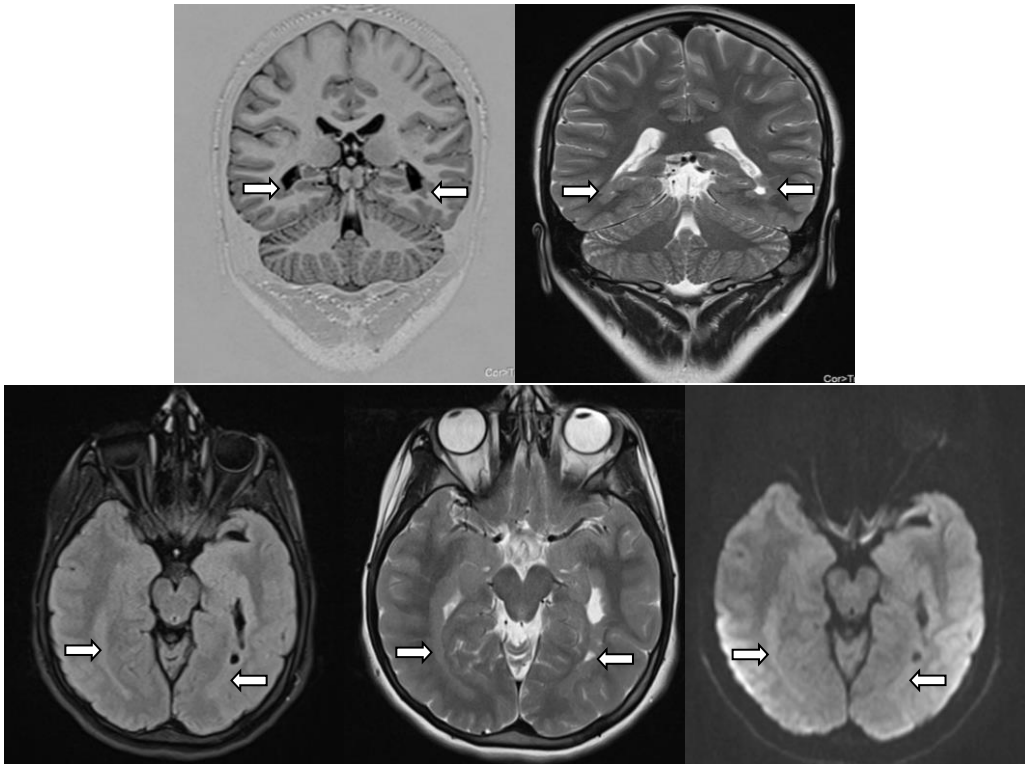

Fig. 1. MRI scan shows bilateral symmetrical bands of ectopic cortex adjacent the temporal-occipital horn of lateral ventricle

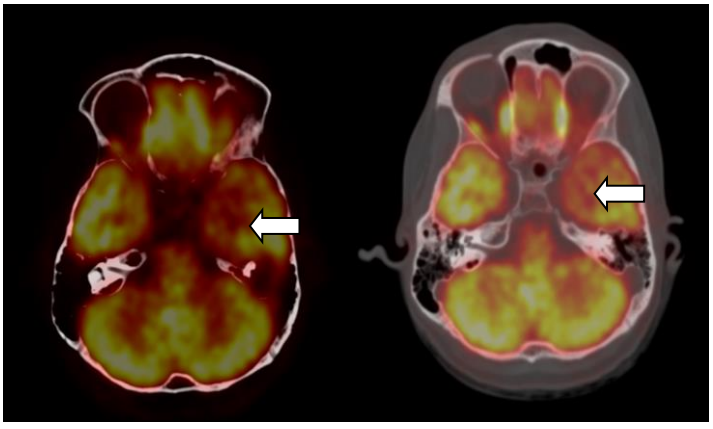

Fig. 2. PET-CT scan shows mesial temporal lobe hypometabolism;

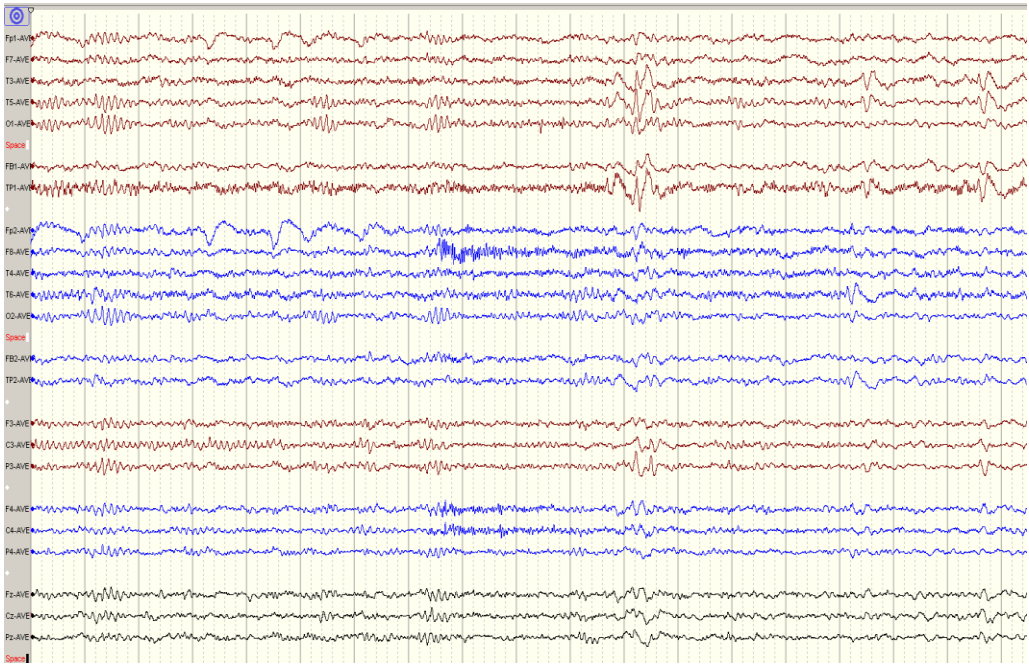

Fig. 3. Interictal EEG: sharp-waves with maximum electronegativity in T3, T5, FB1 and TP1

The patient was referred to an epilepsy center, in order to establish the opportunity for epilepsy surgery. Because of the large and bilateral lesions and the hypometabolism in the left mesial temporal lobe, a conservatory treatment was chosen.

The diagnosis in this case was especially imagistic by highlighting the presence of bilateral band of heterotopia adjacent to the temporo-occipital horn of the lateral ventricle as a marker of neuronal migration disorders.

DISCUSSION

Periventricular nodular heterotopia is a malformation of cortical development, associated with intractable epilepsy. Pharmacoresistant focal epilepsies due to periventricular nodular heterotopia pose a diagnostic and therapeutic challenge, because of the need of invasive presurgical exploration of the brain and the selection of an optimal surgical approach. Invasive electrophysiological exploration in the recent studies, showed that focal epileptic activity can be correlated predominantly, either with one of the nodular heterotopia or with neocortical epileptogenic areas, distant to the periventricular nodules. Thus, using stereo – electro – encephalography (SEEG) methods, it has been showed that both heterotopic and underlying cortex are responsible for ictal onset and interictal discharges (8, 9, 11). The connectivity between the nodular heterotopia and underlying cortex was observed in almost all patients included in studies, using functional imaging studies (PET-CT scans) and diffusion tensor tractography (7).

F-fluorodeoxyglucose (FDG) positron emission tomography (PET) / computed tomography (CT) has been suggested in

patients with PNHs-related epilepsy, to assess the functional activity of ectopic neurons and to identify the epileptogenic foci. Hypometabolic regions in the brain correspond with foci of altered glucose metabolism, due to excessive neuronal and synaptic activity (10).

In our patient, PET-CT scan showed left temporal hypometabolism, demonstrating the connectivity with left heterotopia. The explanation why the activation of cortex was unilateral remains unresolved in our case, due to the lack of neuronal connectivity studies.

From the epilepsy onset, the seizures have not responded to treatment, the frequency being 1-2 per week under treatment with Carbamazepine 800 mg/day and Levetiracetam 2000 mg/day, demonstrating pharmacoresistance. Subsequently, seizures became daily (1-2 seizures/day), which is why the patient was directed to an epilepsy surgery center to determine the opportunity for surgery.

Due to the polymorphism of epileptic seizures, it was concluded that the neural network involved in the initiation and propagation of the epileptic seizures is complex, involving probably both the ectopic cortex and the cortex adjacent to heterotopia, bilaterally. Interesting is the fact that although brain injuries are large and bilateral, the EEG showed preponderant unilateral left interictal and ictal discharge, corresponding with semiological aspects, suggested left temporal lobe epilepsy.

Temporal resections in patients with periventricular nodular heterotopia and intractable focal seizures often yield poor results. In order to define the role of the heterotopic grey matter tissue in epileptogenesis for selective surgery, invasive recordings were necessary up to now. In our case, those investigations were not being performed.

Because of the presence of bilateral and large lesion size, increased operator risk and high rate of recurrence of seizures after surgery, conservative treatment was chosen. The patient is currently undergoing treatment with Levetiracetam 2,000 mg/day, Carbamazepine 1,200 mg/day and Topiramate 200 mg/day (13, 14). It would be of great interest for the patient to benefit from vagus nerve stimulation, but she refused this intervention (12).

Throughout this period, the patient managed to have good school performance, to integrate into society and to have a normal life, but in the last year she accused a decrease in concentration and memory capacity.

CONCLUSIONS

We have presented a rare case of bilateral heterotopia, with pharmacoresistant epilepsy and psychiatric manifestation, in a young girl with normal intellect, with left temporal lobe seizures.

In those cases, the necessity of intracerebral recording and functional imaging is mandatory, to evaluate the connectivity between the heterotopia and adjacent cortex and to predict the benefit of surgery.

Because PNH is bilateral, symmetrical, in a female patient intellectually normal, the genetic test would be of great interest, suggesting the implication of FLNA mutation on X chromosome, but this test was not performed for financial reasons.

The peculiarity of this case is the onset of disease, with psychiatric manifestations and the tendency of recruitment of the left temporal cortex, despite the bilateral heterotopia.

NEWS

COULD BEHAVIOUR CHANGE AND WEIGHT LOSS BE RESTRICTED ?

It is known that Biochemical remission of type 2 diabetes in the absence of pharmacological or surgical intervention has been shown to be achievable. According to new studies, weight loss of ≥10% in the first few years after diagnosis was strongly associated with remission of Type 2 diabetes at 5 years. The most interesting is that this was achieved without intensive lifestyle interventions or extreme calorie restrictions. These results were obtained from a prospective cohort study on 867 people with newly diagnosed diabetes aged 40–69 years, which had a 5-year follow-up. These findings should inform discussions with people who have newly diagnosed type 2 diabetes as motivation towards remission of the disease without restrictive and sometimes unachievable calorie restrictions (Papakitsou I, Vougiouklakis G, Elisaf MS, Filippatos TD. Differential pharmacology and clinical utility of dapagliflozin in type 2 diabetes. *Clin Pharmacol* 2019; 11: 133-143).

QUALITY OF COLLECTED BIOLOGICAL SPECIMENS – THE INVISIBLE PART OF THE ERROR SOURCES IN HEMOSTASIS FOR THE CLINICIANS

QUALITY OF COLLECTED BIOLOGICAL SPECIMENS – THE INVISIBLE PART OF THE ERROR SOURCES IN HEMOSTASIS FOR THE CLINICIANS (Abstract)**:** The introduction of modern analyzers in the laboratories that carry out hemostasis tests has led to the devolution of the sources of error from the preanalytical phase, ensuring results with a high level of reliability. The identification of the non-compliant coagulation specimens due to events related to the biological product collection from the clinic are reported by the laboratories that make these determinations. **Aim:** To inform clinicians about these problems, so that through preventive actions we can ensure optimal clinical management of patients. **Material and methods:** Selective research were conducted in the national and international specialized literature. Inclusion criteria were studies presenting the prevalence and impact of preanalytical errors with the determination of hemostasis tests, as well as recommendations regarding the identification and rejection of the non-compliant samples. **Results:** In the study were introduced works that reported the sources of error which may influence the quality of the laboratory results. The errors associated with blood sampling were related to the samples with hemolyzed plasma, insufficient volume taken and the accidental presence of the clot in the erythrocyte sediment. Available literature data suggests that, out of the total of 75% of the errors identified in the laboratory, 26% can have harmful effects on patient's care, which contribute to unnecessary investigations or to the inadequate treatment and implicitly, extension of hospitalization. **Conclusions:** Applying corrective measures can improve the quality indicators of the coagulation specimens and implicitly the quality of the patient's health care by informing clinicians and using educational activities. **Keywords:** HEMOSTASIS, HEMOLYSIS, VOLUME, CLOT, EDUCATION.

Available literature data suggest that errors once appeared with the sampling of the biological product can have very serious consequences on the patients care, since the medical decisions are made in a proportion of 60 to 80% based on the laboratory tests results (1, 2, 3). Because the technique of sampling the biological product is an invasive and complex procedure, it is performed in the clinic and is considered a pre-analytical phase. This aspect represents a major error source in the testing process (4, 5, 6, 7).

In order to minimize possible errors on

the determinations, improvement of the analytical phase in the laboratory was desired by modernizing and automating the methods of coagulation tests determination, being able to provide very precise results (3, 8). In 2005, van Geest-Daalderop *et al.* in their study mentioned that oral administration of the anticoagulants with coumarin derivatives depends on PT/INR (prothrombin time/ international normalized ratio) results, evaluating the effect of preanalytical variables on test determination, including those related to the sampling and transport of samples (9).

In the national literature, in agreement with the international specialized literature, among the causes of rejection of the samples taken for the determination of PT and APTT (activated partial thromboplastin time) tests, are mentioned: insufficient volume taken, less than 90% (0.5 mL blood less) of the recommended volume (4.5 mL blood), intensely hemolyzed plasma and the whole coagulated sample, as described in (fig. 1) (10).

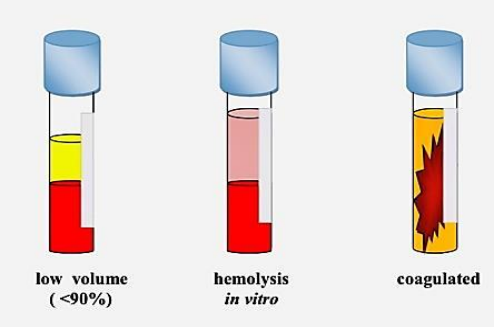

Fig. 1. Representation of the causes of rejection of the coagulation specimens (personal collection)

OBJECTIVES

The purpose of this study is to inform clinicians about the negative interference of error sources from the pre-analytical phase, with the determination of coagulation tests, to better understand the possible discrepancies between the results released by the laboratory during dosing and the monitoring of anticoagulant therapies. Emphasizing the need for educational activities in order to reduce the incidence of preanalytical errors that generate non-compliant blood samples.

MATERIAL AND METHODS

In order to investigate the topics of interest, it was chosen as a means of using existing data to review the literature. It was desired to use primary sources based on evidence, which used different methodologies and theoretical comments, on the effect of preanalytical factors on the samples taken for the determination of hemostasis tests.

To make a comprehensive approach regarding the negative impact of the sources of error from the pre-analytical phase on the determination of coagulation tests PT and APTT we performed a search on PubMed and Google Scholar.

INCLUSION CRITERIA

To select this information, we looked for original studies, reviewed by colleagues that describe the pre pre-analytical and post post-analytical phases in the testing process. We considered the study protocols, conclusions, as well as the reported cases. This study has some limitations represented by the impossibility of approaching all articles dealing with preanalytical factors and the consequences on hemostasis tests. The level of the works number approached is quite small, but despite this fact, based on the selected studies, as well as the presentation of the conduct in our laboratory, we want to draw

attention to the sources of error regarding the quality of the sample taken.

RESULTS

In our research, we were able to introduce studies that analyzed the changes occurred during the test process to determine PT test and APTT in the hemolysate samples, with insufficient volume taken and the accidental presence of the clot in erythrocyte sediment.

The selection of the most recent national and international studies (2014-2019) was abstracted using a table, starting from the design mode, objectives, methods of evaluation, sample size and conclusions; implicitly based on the keywords: pre-analytical, post-analytical, coagulation, errors, hemolysis, volume, clot, procedure, false, rejected, education, patient, clinician, nurse, laboratory medicine, trust; as described in first table.

DISCUSSION

Favaloro *et al*. in their study mentioned that between 9 and 15% of errors are the result of a misdiagnosis, with a significant impact on the patients care, and the probability of inadequate care represents between 2-7% of such cases, agreeing with Plebani's study (8, 11). Errors resulting from inadequate sampling, associated with improper handLing and processing of samples, will reflect the status of the sample taken and will not accurately reflect the actual clinical status of the investigated patient, being considered pre-analytical variables (8).

In 2016, Magnette *et al*., point out that the ratio of blood taken and Na citrate of (1:9) for coagulation tests, (12) must be respected, corresponding to 0.5 mL anticoagulant and 4.5 mL blood, quantities recommended in the national literature since 1959 (13). A volume of blood taken less than 89% of the recommended amount (0.5 mL blood missing) interferes with the determination of the APTT test, which is clinically significant, and a volume of 78% (3.5 mL blood taken) affects fibrinogen determination, and less than 67% (lacking 1.5 mL of blood) from the recommended volume affects factor VIII (Antihemophilic A) determination, being in agreement with the subsequent studies (7, 12, 14, 15). In our laboratory, in cases where the sample has a lack of 0.5 mL blood, in order to inform the clinician, the non-compliance is explained textually, once the result is released, with the following comment: "Sample with insufficient volume taken, lack 0.5 mL of blood; possible interference with the determination". Leblanc, Ellouze and Guermazi recommend rejecting the sample, if the vacutainer has a volume of less than 80% (1 mL of blood is missing) (16, 17). In accordance with these recommendations, we reject the determinations made in these samples, explaining to clinician the non-compliance: "Repeat the sampling. Sample with insufficient volume taken, 1 mL of blood is missing".

In medical laboratories, the receipt of samples with plasma hemolysis is a common phenomenon, representing a reason for refusing the determinations (8, 18, 19). Some authors believe that this rejection creates discomfort for the patient, delayed outcomes and additional laboratory costs (19, 20). Most of the time, in the laboratories carrying out hemostasis tests the interpretation of the *in vitro* hemolysis, is performed post-centrifugation, by visual examination (21). From a technical point of view, plasma hemolysis can be classified according to the hemoglobin concentration in the supernatant:

a) non-hemolysis (0.05 g / L, yellow)

b) slightly hemolyzed (from 0.05 to 0.3 g / L, toned yellow to light pink)

c) medium hemolyzed (0.3 to 0.6 g / L, pink to slightly red)

d) hemolysis (0.6 to 2.0 g / L, slightly red)

e) intensely hemolysis (2.0 g / L, red to brown), as exemplified in (fig. 2) (21, 22).

As the assessment is done by the laboratory assistant who prepares the samples for the analysis itself, it would be ideal to use color diagrams for the correct interpretation of the degree of hemolysis (22).

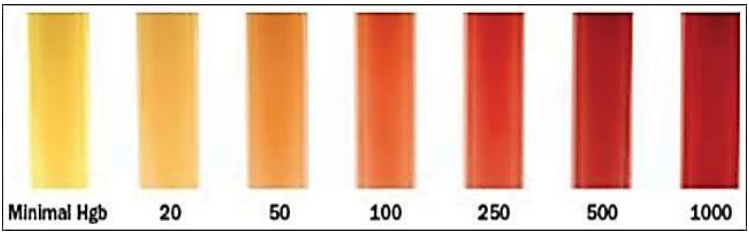

Fig. 2. Color diagram for in vitro hemolysis detection.

The numbers indicate the degree of hemolysis expressed in mg/dL (22).

Favaloro *et al*. draws attention to cell lysis products that include tissue factors which activate coagulation, and, as hemolysis increases, fibrinogen levels may decrease, D-dimers increase, while APTT may increase or decrease. Through the activation effect, PT test values may decrease depending on the fibrinogen decrease (8). Laga *et al*. and Arora *et al*. concludes on the basis of the research carried out on the samples of the healthy volunteers, that the differences of the results were insignificant, and the statistical difference found does not have clinical significance. This hypothesis is safe if the result falls within the normal reference range, with no certainty for the results at the lower or upper limit (20, 23).

Using different reagents for test determination, Woolley *et al*. observed no correlation between variations in results and level of hemolysis (24). Wan Azman *et al.* recommends standardizing the interpretation of hemolyzed plasma samples and drawing up a laboratory guide, thus providing essential information to clinicians (25). However, the results being controversial, further studies on larger groups are needed to determine the effect of hemostasis (19). Rejecting the samples with hemolyzed plasma being considered inadequate, it is recommended to add a brief comment that suggests doubt about the interpretation of the results and their benefits for the patients care (26, 27,

28). In accordance with these recommendations, in the case of hemolyzed plasma samples, we inform the clinician, releasing the result with the following comment: "Hemolyzed plasma sample, possible interference with the determination".

Current analyzers for coagulation tests determination can detect in the pre-analytical phase fibrin, foam, hemolysis plasma, as well as insufficient blood volume is taken (29), without being able to detect the accidental presence of the clot in the erythrocyte sediment, as described in (fig. 3).

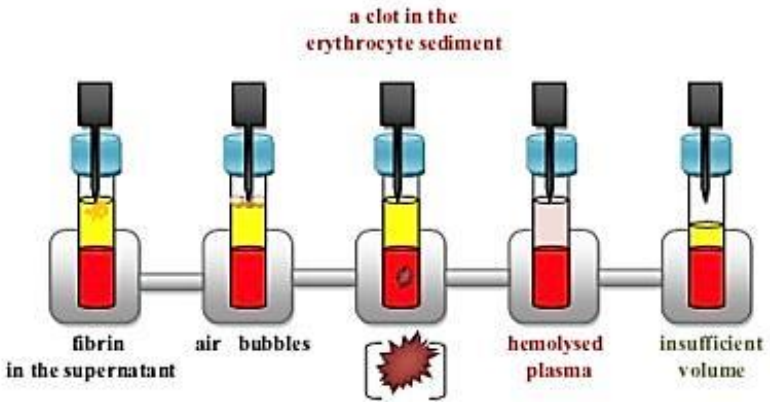

Fig. 3. Detection of fibrin, foam, hemolysis in the supernatant, the insufficient volume is taken and clot in the erythrocyte sediment (personal collection)

Total blood coagulation *in vitro* (fig. 1) is caused by the loss of cellular elements, as well as the factors such as: fibrinogen, prothrombin, proaccelerin, anti-hemophilic A, and differentiated loss of von Willebrand factor, leading to the serum formation (8). Determination of hemostasis tests from partially coagulated samples, as a consequence of the clot presence *in vitro* (fig. 3) may result in false shortening or prolongation of coagulation tests, because the differentiation between plasma and serum is difficult to perform post-centrifugation by visual inspection (8, 28).

In our laboratory, starting with 2014, in order to exclude or confirm the presence of the clot in the erythrocyte sediment during the test, we also re-verify post-analytically by transvasation (fig. 4) (30, 31) the samples with hemolyzed plasma, in agreement with Favaloro *et al*. as well as the samples from which false or possibly false tests are obtained (8). In the case of clotting, the results are canceled and recommended sampling repeat, textually explaining the non-conformity: "Sample with clot. Repeat the sampling".

Fig. 4. Detection of the clot by transvasation (personal collection) (30, 31*)*

Clinical departments ensure the selection and tests recommending, sampling, handLing, transport and preparation of samples for analysis, a process that begins and ends with the patient, that's why we can consider that patients are also part of this team (32). It is important to maintain total control of the testing process in a systematic and transparent manner, encouraging and promoting errors identification, because, if the team fails, patients will suffer the most (32, 33). For patient's safety, nurses must be aware of the influence and possible consequences of preanalytical errors on laboratory results (32).

The recognition of these aspects is a challenge for the nurses who have an important role in the handling and sampling, an activity that should be considered as a necessary competence, and not just a technical trick (35). Being in agreement with previous studies (8, 17, 20, 34), from 2015, we pay special attention in the identification and monitoring of non-compliant samples (35), which represents error source for determining coagulation tests: insufficient volume has taken (lack of 0.5 mL blood), plasma hemolysis, as well as the presence of the clot identified in erythrocyte sediment post-analytical. In this way we can minimize the effects of biological factors that might have a significant impact on patient care.

It is necessary to train the nurses during the service, as well as to introduce in the syllabus the basic theoretical aspects regarding correct sampling technique of the biological product (32). Makitalo and Liikanen state that, through multi-professional cooperation, involving laboratory staff, the number of errors in the pre-analytical phase could be reduced (32). Guder in his article (36) mentions that the term preanalytical phase was included in textbooks in 1983 (37), and in the teaching books of Laboratory Medicine in 1987 and 2005 (38, 39). The lack of a standardized training program and periodic skills assessment has an impact on the quality of the results (40, 41, 42). Crous and Armstrong believe that errors during sampling can produce negative outcomes for the patient, which can vary from financial implications to death, according to the study of Al-Ghaithi *et al.* (41, 42).

In 2017 we presented the importance of the laboratory specialists involvement in errors reducing from pre-analytical phase through a training based management and acquired knowledge verification of the medical personnel (43), being in accordance with Al-Ghaithi's study (44), continuing in 2018 with a study, by which we drew attention to the false hypercoagulability *in vitro*, as a result of highlighting the error sources regarding the quality of the sample taken (45).

The focus of patient care, accepted on internationally level, changes the responsibility and delivery of healthcare (45). Medicine laboratory through a tripartite collaboration with clinicians and patients who are the beneficiaries of these services should include this change (46). The involvement key is enhanced by better communication, knowledge management, information disseminations, and educational support (46, 47). In the paper presented by Wu *et al.*, one of the 10 topics addressed refers to communication with clinicians and to laboratory role in educating clinicians about preanalytical and analytical influences on outcomes (48). Highlighting the importance of these errors is necessary for the clinician, who decides which tests to recommend in the pre-preanalytical phase, following by post post-analytical to decide the

appropriate treatment based on the laboratory results received (49). These aspects are supported by available literature data regarding incorrect diagnosis associated with laboratory test errors (50, 51).

CONCLUSIONS

We wanted to emphasize through this work, that evaluation of medical services quality in laboratories has become more and more important, both for the pressures exerted to reduce the additional costs due to the repetition of the determinations, but also for the evidence of the wrong diagnosis associated with the error sources tests.

The impact in the case of false results, generated by the interference of the error sources with the determination of the coagulation tests, can be especially serious because, in the case of specialized hemostasis tests, these are often considered "diagnostic". That's why we consider being very important identifying error sources before the results are released to the clinician and before to became a real harm for the patient's life.

Establishing a permanent link between clinicians and laboratory specialists would be useful by combining the unique talent of knowing the physiological reason behind the tests and conducting quality laboratory analyzes.

In order to ensure the quality of hemostasis exploration, we strongly support the creation of an initiative for developing the continuous educational programs for health professionals, representing also a priority for medical institutions.

PATENT FORAMEN OVALE–A RARE CAUSE OF RECURRENT ACUTE OPTIC NEUROPATHY AND CEREBROVASCULAR EVENTS (Abstract): We report the case of a young female patient who developed recurrent acute bilateral and asymmetric vision loss, associated with pain and paresthesia on the right half of the body. Brain and spinal cord MRI showed inactive gliotic lesions, not suggestive of multiple sclerosis-related diseases. A wide range of autoantibodies were tested to exclude neuromyelitis optica, an autoimmune systemic disease, a paraneoplastic neurological syndrome or an autoimmune channelopathy; all came back negative. Cardiac examination and transthoracic echocardiography revealed persistent foramen ovale (PFO). Paradoxical ocular and brain embolism was the presumed cause of patient's uncommon clinical features. She underwent percutaneous closure with 25mm septal occlude, followed by permanent antiplatelet therapy, with favorable clinical outcome. **Conclusions:** This case is a unique association of recurrent PFO-related ocular and neurologic symptoms and emphasizes the necessity of considering cardiovascular causes among young patients who present with transient vision loss. Medical imaging was extremely important both in diagnosis and minimally invasive treatment, with favorable outcome and social reintegration of the patient. **Keywords:** OPTIC NEUROPATHY, PARADOXICAL EMBOLISM, PERSISTENT FORAMEN OVALE, CEREBROVASCULAR EVENT.

Acute optic neuropathy is the most common cause of vision loss, and it is a serious condition with a profound impact upon patient's quality of life. The etiology of acute optic neuropathy may be inflammatory, infectious, ischemic and traumatic. A careful history of patient's associated conditions and symptoms can help refine and narrow the differential diagnosis and select the appropriate therapeutic approach. In a young patient, a history of eye pain associated with eye movement, prior history of neurological symptoms such as paresthesia, limb weakness, and ataxia is suggestive of demyelinating optic neuritis, or, less frequently, of systemic vasculitis. In children and young adults, if visual loss is preceded by flu-like symptoms, sinusitis, or there is a recent vaccination history, the diagnosis is most probably parainfectious or post-vaccination optic neuritis, respectively. Personal history of atherosclerosis or blood diseases may be associated with ischemic optic neuropathy. Jaw claudication, temporal pain, fatigue, associated biological inflammatory symptoms are signs of giant cell arteritis, which can affect optic nerve perfusion by small vessel

vasculitis. Yet, in some cases, there are diagnostic challenges and an interdisciplinary approach is required.

CASE REPORT

We report the case of a 29-year-old woman with no significant personal history, admitted for sudden loss of vision in her right eye (days), intense photophobia and ocular pain exacerbated by eye movements and bright colors, accompanied by lower back pain and paresthesia on the right half of the body.

The eye exam revealed severely decreased visual acuity, of 0.05 in the right eye (RE), with constricted visual field, both for white light and colors. Ophthalmoscopy of the RE revealed hyperemic optic disk, with mild edema in the superior sector. Left eye (LE) was normal.

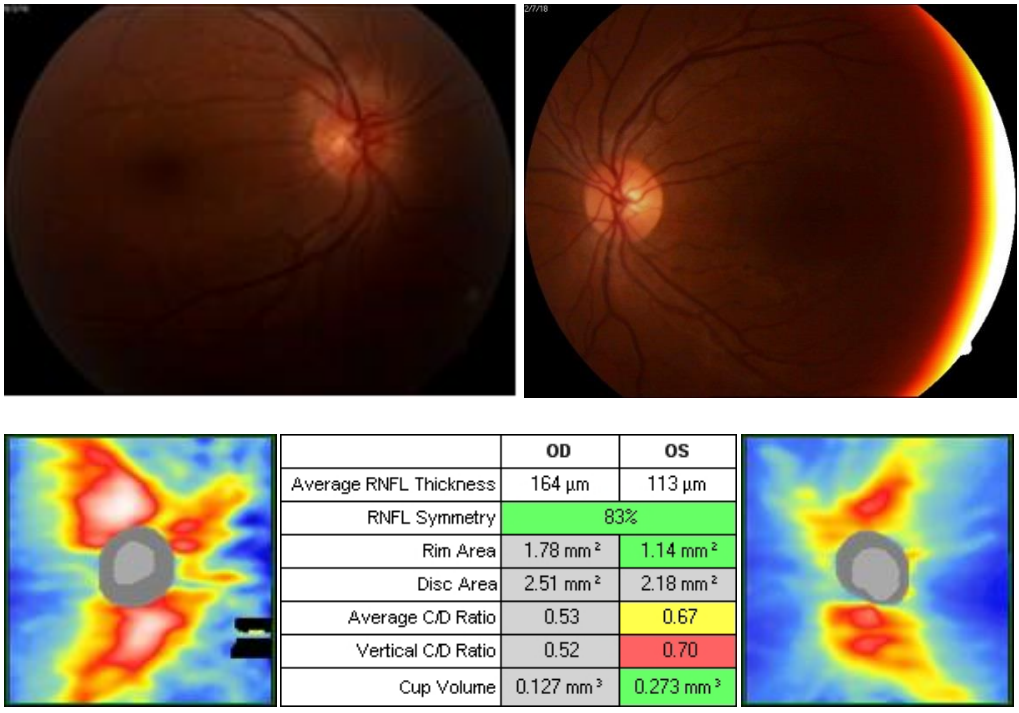

Fig. 1. a) Fundus appearance: RE - mild edema of the superior sector of optic disk; b) LE - normal appearance c) OCT exam of the optic disk: hyperemic optic disk, mild peripapillary retinal nerve fiber layer edema in the RE, superior sector

Based on the clinical ocular and neurological symptoms, the probable diagnosis was: RE acute optic neuropathy, in observation for multiple sclerosis. Other possible causes considered were a systemic autoimmune disease, a neurological paraneoplastic syndrome, reaction to a systemic or regional acute infectious disease, or an ischemic mechanism.

MRI exam showed some small, well-delineated, inactive gliotic lesions, situated deep subcortically, in the parietal and occipital area, not meeting the criteria for an acute demyelinating disease.

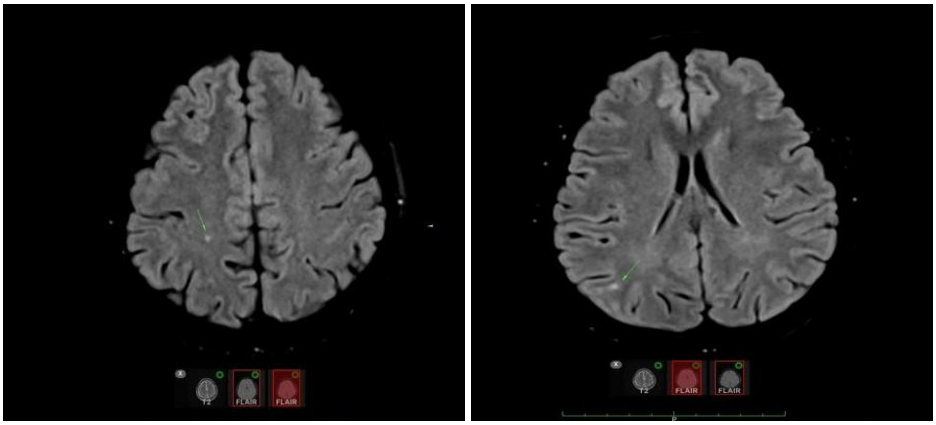

Fig. 2. MRI: small, inactive gliotic lesions, probably of ischemic origin, located occipitally and parietally

All laboratory test results were normal, showing no signs of biological inflammatory syndrome (C3, C4, rheumatoid factor, immunogram, lactate) or systemic infection. The extensive array of immunological tests were all within normal ranges: serum anti-aquaporin- 4 and anti-Mog autoantibodies, anticardiolipin autoantibodies, anti-beta2-glycoprotein autoantibodies, ANA, c-ANCA, p-ANCA, anti-double-stranded DNA autoantibodies, anti-ro (SS-A), anti-La (SS-B), onconeural autoantibodies, IgG4s profile, anti-VgKCA autoantibody.

While still investigated and in process of recovery, the patient presented a bilateral asymmetric acute visual loss, more severe in her RE, urinary functional complains (retention), paresthesia and painful hyperesthesia on the right half of the body, with difficulties holding an object in her right hand, and a walking perimeter limited at about 200 m.

Ophthalmological exam revealed: visual acuity (VA) hand movement in the RE and 0.1 in the LE, and bilateral visual field contraction of 10º in her RE and 30º around fixation point in her LE.

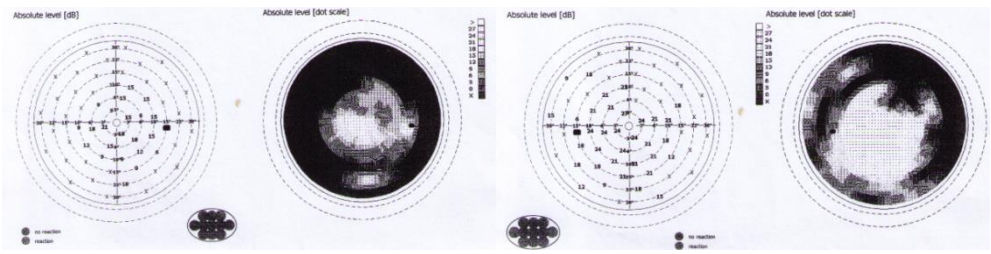

Fig. 3. a) Visual field of the RE; b) Visual field of the LE

The fundus exam in the RE revealed the same optic disk appearance, with mild peripapillary edema, more intense in the upper quadrant, and 2 new small whitish retinal lesions in the super temporal sector, which could be either a sign of retinal vasculitis or micro embolism. LE was normal. Visual evoked potentials revealed increased P100 latency in both eyes (RE 146 ms, LE 123 ms).

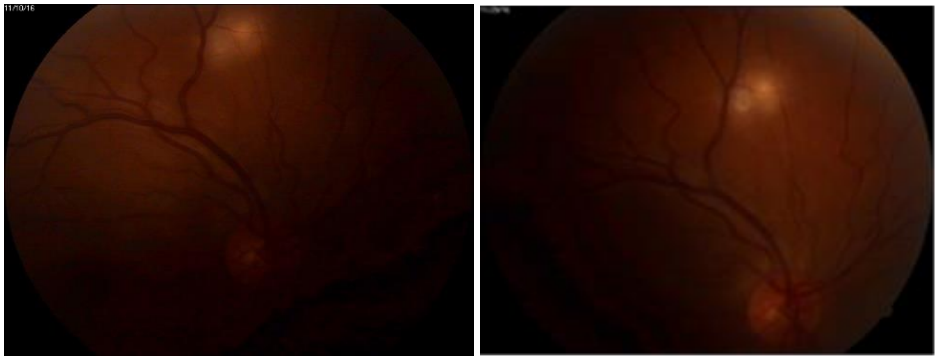

Fig. 4. Fundus Photography of RE: 2 new whitish, ill-defined retinal lesions
(a) with slow progression to focal atrophy
(b) located in the superior sector, centered by a small vessel in the superotemporal sector

As all laboratory results and rheumatological examination excluded a systemic vasculitis, the patient was referred to a cardiology consultation in search of a possible cause of an ischemic event. Physical examination revealed a 1/6 grade systolic murmur and color Doppler echocardiography evidenced a patent foramen ovale 5 mm in diameter.

The final diagnosis was recurrent bilateral optic neuropathy and transient ischemic attack. Persistent foramen ovale. A recurrent paradoxical micro embolism was considered to be the cause of both the ophthalmic and neurologic findings, with immediate indication for percutaneous surgical closure. The 25 mm ASD occlude was introduced loaded and with a delivery guide via a 6F sheath placed in the right femoral vein, progressed via a Cournand catheter and positioned at the level of PFO under 3D echocardiography guidance. She was prescribed permanent antiplatelet therapy (aspirin 75 mg/day) and vitamin B complex supplements for 3 months.

Fig. 5. a) control coronarography of the septal occluder at the end of surgical intervention;
b) follow-up echocardiography 6 month later

The course was favorable, with progressive neurological and ophthalmological recovery. One month after the intervention, she came back in for an ophthalmologic

exam which revealed normal visual acuity and slight peripheral visual field constriction in both eyes. The 2 retinal lesions showed a slow progression to focal atrophy. During the 12-month follow-up period, no relapse was recorded, and the patient could resume her normal daily routine and even work.

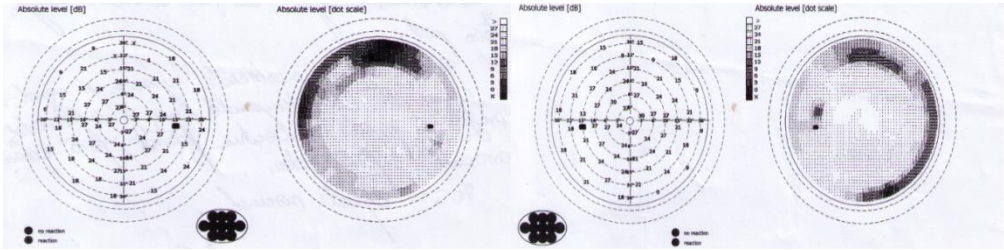

Fig. 6. a) Visual field of the RE – final appearance;
b) visual field of the LE – final appearance.

DISCUSSION

Patent foramen ovale is one of the most frequent congenital cardiac malformations, encountered in about 20-30% of subjects (1, 2). In most cases, it is a benign condition, and surgical closure is not routinely recommended. However, the presence of this abnormal right-left atrium communication can be responsible for paradoxical systemic embolism. Neurologic events are encountered in about 1-2% of persons with PFO requiring surgical closure to alleviate the symptoms, but ophthalmological features are even less frequent (2, 3). The neurologic signs of PFO-related ischemic events are: sudden weakness of face, arm or leg, swallowing difficulties, dizziness, loss of coordination, sudden paralysis or paresis, difficulty speaking and understanding words or simple sentences. On the other hand, among subjects with cryptogenic stroke, the incidence of PFO is of 40%, suggesting a strong cause-effect relationship between the two pathological conditions (4). There are only a few reports of vision loss associated with PFO, caused by central or branch retinal artery occlusion, yet in none of the cases concomitant ocular and cerebrovascular ischemic events were described (5-11).

The efficacy of PFO closure in preventing cryptogenic stroke was a subject of controversies in the last years. Recent studies confirm a significant decrease of the relative risk or neurologic events up to 58% in cases with percutaneous PFO closure vs medical therapy, especially in young patients aged <60 years (12-15). On the other hand, the absolute risk of cryptogenic stroke decreases only with 2.6-4.8% after PFO occlusion (13, 15), suggesting that other factors may be involved, especially in older people, like dyslipidemia or atherosclerosis. Periprocedural risk is estimated at 3% and the possible adverse events described in literature are: hemorrhages, embolic events, arterio-venous fistulas, retroperitoneal bleed, peripheral ischemia or a need for a vascular surgical repair (15). Episodes of atrial fibrillation may be related to local inflammation or device induced arrythmia. Presently, PFO closure indication is restricted to young patients, who experienced cryptogenic stroke (12). In these cases, the long-term benefits are proved to overcome the relative procedural associated risk.

In a young patient with sudden visual loss and neurologic symptoms, the most frequent cause is multiple sclerosis followed by systemic vasculitis; ischemic optic neu-

ropathy is extremely rare. The lack of laboratory data to support the clinical symptoms was a challenge for establishing the diagnostic and therapeutic approach. The ophthalmologic exam documented the acute ischemic disease and oriented the clinical investigations toward finding the cause. The favorable outcome was due to the small areas affected by emboli, which allowed patient's almost full recovery, and also to the early diagnosis and treatment of the underlying cardiac condition.

CONCLUSIONS

This case report presents a unique association of PFO-related recurrent ocular and neurologic ischemic events and emphasizes the necessity of considering cardiovascular causes even among young patients who present with transient vision loss.

Medical imaging was extremely important for diagnosis and minimally invasive treatment, with favorable outcome and social reintegration of the patient.

DIAMOND-BLACKFAN ANEMIA. CASE REPORT (Abstract): Diamond – Blakfan Anemia (DBA) is a rare condition in pediatric pathology, with more than 500 cases described in literature. It is a congenital eritroblastopenia, with AD/AR/ X-linkage inheritance, 90% were diagnosed by one year of age. Physical appearances were abnormal only in 29%. The current recommendations are corticosteroids, with suportive treatment and bone marrow transplantation. In general, DBA remains a single cytopenia. Long term prognosis remains uncertain, DBA is a preleukemia condition.We present you two cases that we took care of in our clinics.
Key words: BLACKFAN-DIAMOND ANEMIA, CONGENITAL APLASTIC ANEMIA

LAPAROSCOPY IN ACUTE ABDOMINAL DISORDERS

LAPAROSCOPY IN ACUTE ABDOMINAL DISORDERS (Abstract): In emergency preoperative diagnosis is most accurate in acute cholecystitis and least accurate in pelvic conditions and mesenteric ischemia. Laparoscopy has a double goal: establish or confirm diagnosis and treating the disorders. Laparoscopy identifies those patients who do not need surgery. Our experience includes 2,778 patients with surgical acute abdomen: 1,857 cases with acute cholecystitis, 719 cases with acute appendicitis, 57 cases with perforated peptic ulcer, 10 cases with intestinal obstruction on postoperative adhesions, 19 cases with abdominal trauma, 87 cases with acute adnexal pathologies, 4 cases with acute pancreatitis, 12 cases with mesenteric ischemia, 12 cases with abdominal abscesses and one case with false acute abdomen. Our experience clearly shows the feasibility and safety of the laparoscopic appendectomy. The minimal access approach brings back suture in the treatment of perforated peptic ulcer in the conditions of an efficient postoperative medical treatment. Keywords: LAPAROSCOPY, ACUTE ABDOMEN, UNNECESSARY LAPAROTOMIES.

The recent expansion of both diagnostic and therapeutic laparoscopy has added a new tool to the surgical armamentarium. Laparoscopy is an efficient method for diagnostic in surgical acute abdomen because usually allows a good view of the uterus and adnexa, the appendix, the gallbladder, the stomach, the pylorus, and the first portion of the duodenum.

The laparoscope was introduced to determine whether the laparotomy would be required. With the development of new techniques, it has become possible to perform definitive therapeutic procedures under videoendoscopic control in the setting of the acute abdomen.

Laparoscopic appendectomy and closure of perforated duodenal ulcer have become common procedures, and laparoscopic cholecystectomy is now the standard of care in acute cholecystitis.

Laparoscopy can be used to assess intestinal viability if bowel ischemia is suspected.

MATERIAL AND METHODS

Between January 2013 and March 2020, in the First Surgical Clinic, from "Sf. Spir-

idon" County Clinical Emergency Hospital, Iasi were performed 8,367 laparoscopic interventions; 2,778 interventions of these (33,2%) were performed in emergency.

Laparoscopies establish the following diagnostic: Perforated peptic ulcer – 57 cases; Abdominal trauma – 19 cases; Intestinal infarction – 12 cases; Intestinal obstruction – 10 cases; Acute appendicitis – 719 cases; Acute adnexal pathologies – 87 cases; Acute cholecystitis – 1,857 cases; Acute pancreatitis – 4 cases; abdominal abscesses – 12 cases; False acute abdomen – 1 case.

RESULTS

8031 laparoscopic cholecystectomy was performed in our clinic for various anatomoclinical form of cholecystitis. Laparoscopic cholecystectomy for acute cholecystitis was performed in a series of 1857 patients (71.9% women and 28.1% men) with mean age 50.4 years (between 18 and 82 years). Obesity was encountered in 78% of the cases. Clinical aspect was typical for acute cholecystitis in 93.7% of the cases. In all cases diagnosis was confirmed or suggested at ultrasound examination. In most cases acute cholecystitis was related to gallstones presence; only 5.7% of the cases were not determined by lithiasis.

At pathology, the lesions were: edematous acute cholecystitis (72.3%); phlegmonous acute cholecystitis (8.1%); gangrenous acute cholecystitis (9.5%); plastron (11,1%).

Intraoperative in 80% of the cases we found pericholecystic adhesions. In 31.2% Hartmann pouch was placed behind porta hepatis. This was not surprising because with an inflamed gallbladder the anatomy in the area may be severe distorted. If the dissection was difficult or the ductal anatomy was not clear we converted to open cholecystectomy, because in this conditions the risk of ductal lesions is rather high. Conversion rate in this series was 9.1% (169 cases) as compared to a 2.8% rate in the entire series of laparoscopic cholecystectomies. The rate of biliary lesions was 0.1%.

Decompression of the enlarged gallbladder was needed in 80% of the cases.

We encountered the following intraoperative complications: gallbladder perforation (31.8%); hemorrhage (16.8%); gallstone loss (11.2%).

Mean operating time was 78 minutes (25-130 minutes), much longer than the mean value for laparoscopic cholecystectomy in general. Bottom line is that the intervention was easy in only 7.8% of the cases. In most cases we gave antibioprophylaxis. Postoperative morbidity was low, 5.6%. Mortality was 0.18% (2 cases – the cause was pulmonary thromboembolism). Mean postoperative hospitalization was 3.8 days. Laparoscopic cholecystectomy can be performed routinely for acute cholecystitis. Laparoscopic appendicectomy was performed on a series of 719 patients (81% women and 19% men). Their age was between 12 and 68 (mean 23) years.

Laparoscopic appendicectomy was indicated in the following situations: women at the reproductive age, because of the difficulties of establishing an accurate preoperative diagnosis in their cases; in our series the diagnosis error rate in this group was 20%; obesity, present in 32% of the cases; young patients; sportsmen.

At pathology, the lesions were: edematous appendicitis (61.5%); phlegmonous appendicitis (25.3%); gangrenous appendi-

citis (7.6%); plastron (5.6%).

The technique used was: "in" in 120 cases (16.7%); "out" in 252 cases (35%) and mixed in 298 cases (41.49%). Conversion rate was 6.81% (49 cases).

Morbidity was: 4 cases with parietal hematomas (0.55%); 5 cases with wound infections (0.69%).

Complications encountered were: 2 cases with peritonitis (6th day postoperative) 0.27%. Mean hospital stay was 3.2 days.

In our experience laparoscopic appendicectomy has certain advantages allows diagnosis of other conditions; decreases wound infection rate; deceases hospital stay; decreases recovery time for the patient; best cosmetic results.

Laparoscopic closure of duodenal peptic ulcer was performed in a series of 57 patients (all men) with mean age 28 years (between 18 and 58 years). The presentation was at 1-10 hours after symptoms onset. Preoperative diagnosis was perforated ulcer in most cases, pneumoperitoneum being present in 55 cases. At presentation, the patients had acute abdomen symptoms; perforations were small (< 5 mm) in all cases. Suture closure with an omental patch was performed in 57 cases. It is very important to wash and drainage very well the peritoneal cavity. Laparoscopic intervention offers this possibility. In only one case an inadequate closure leaded to a leak and after two days we performed a classic intervention. There were no other complications, and the morbidity was zero. Mean postoperative hospitalization was 4.6 days. Postoperative all patients received medical treatment for ulcer and sterilization of *Helicobacter pylori*. At follow-up after 3 months and a year there was no recurrent peptic ulcer in all cases.

Open laparoscopy was performed in 10 cases of intestinal subacute obstruction by postoperative adhesions. In only 5 cases was possible to performed adhesiolysis. In all other cases we had to convert to open procedure.

Laparoscopic surgery for abdominal trauma was performed in 19 cases, 5 cases for wound trauma and 14 cases for abdominal blunt trauma (hemoperitoneum). In abdominal blunt trauma intraoperative diagnosis was 3 hepatic lesions (II-III Moore degree) for who was performed exploration and hemostasis with Argon beam and TachoComb® (superficial injury of the liver) and 11 splenic lesions (II-III Moore degree) for who we performed laparoscopic splenectomies in 3 cases (rupture hematoma spleen), laparoscopic diagnosis with conservative treatment and spleen preservation in 2 cases and 6 conversions with spleen preservation in one case (packing with resorbable prosthesis).

Laparoscopic procedures were performed for acute adnexal pathologies in 87 patients. In cases with torsion of the ovary was required oophorectomy. In 6 cases with tubal pregnancies, we performed 3 salpingostomy and 3 salpingectomy, respectively. Otherwise, there were cases of ruptured ovarian cysts hemorrhagic. We did not include cases of pelvic inflammatory disease.

Other causes of acute abdomen in which we intervened by means of laparoscopy were: 4 cases of acute pancreatitis and 10 cases with bowel ischemia. In all this 4 cases an open laparotomy was avoided.

DISCUSSION

Many of the causes of the acute abdomen can be managed by laparoscopic ap-

proach (1). The therapeutic approach in these patients is based on clinical suspicion and on the results of diagnostic laparoscopy. Each procedure started by performing diagnostic laparoscopy to determine the specific abnormality present. Laparoscopy has become a routine procedure in the management of acute abdominal disease and can be considered both an excellent therapeutic and additional diagnostic tool in selected cases (2).

The diagnostic of acute cholecystitis is usually made preoperatively by clinical examination and ultrasound exploration. Sometimes acute cholecystitis may present as an acute abdomen if the gallbladder is gangrenous or perforated. Grasping of the gallbladder can be difficult when an acute state is present. We do not hesitate to decompress the gallbladder to improve the ability to grasp an acute inflamed gallbladder.

Laparoscopic cholecystectomy can be routinely performed in acute cholecystitis, but the surgeon must be prepared to convert to open cholecystectomy. If there is necrosis or the gallbladder cannot otherwise be retracted, then the operation should be converted to open approach.

It is also important to not spend to long with the laparoscopic technique if the dissection is difficult or the ductal anatomy is not clear.

The complications are more frequent in laparoscopic cholecystectomy than in open method. Bleeding from the liver can be a significant problem. Bile leaks can occur the cystic duct where a clip has fallen off.

Endoscopic retrograde cholangiopancreatography is used to identify the site of the ductal leak and to rule out injury to the common bile duct.

Common bile ducts injuries typically occur when the common duct or the right hepatic duct have been misidentified as the cystic duct. This injury is preventable by performing meticulous dissection beginning at the junction of the neck of the gallbladder and the cystic duct.

Indications for laparoscopic appendectomy include patients with an uncertain diagnosis (elderly, reproductive age females), obese patients, and those with suspected perforated appendicitis.

Laparoscopic management of perforated appendicitis is superior to open technique.

Dissection of adhesions and the irrigation of the entire abdominal cavity can be realized without extension of the incision. Simultaneously, another cause of acute abdomen can be identified and operatively managed. Obese patients have an increased wound infection rate and require larger incisions for open procedure. Further advantages of the laparoscopic technique include decreased exposure of subcutaneous tissue to the infected appendix and therefore a lower infection rate (3). It is better to performing appendectomy even if the organ appears normal (sometimes the appendiceal inflammation can be detectable only at the microscopic examination).

The preoperative diagnosis of perforated peptic ulcer is usually simple established by clinical examination and presence of air in peritoneal cavity on the abdominal radiographic films. The laparoscopic approach brings back the suture closure with an omental patch in the treatment of perforated duodenal ulcer. The modern medical treatment of peptic ulcer avoids the recurrent ulcer.

If the perforation is small and surrounding tissue is healthy it is possible to per-

formed direct closure using 3-0 polyglactin suture closure on atraumatic needles. It is better to close the defect in a transverse direction to prevent narrowing of the lumen.

Large perforations or those with large amount surrounding tissue friability and edema can be closed with an omental plug. The peritoneal cavity must be thoroughly irrigated with warm saline solution. Tilting the table in different positions helps with irrigating the entire peritoneal surface (4).

"Kissing ulcers" can occurs in which there is an anterior perforation and posterior penetration with bleeding. In these conditions it may be necessary to convert to laparotomy.

Acute abdominal pain from gynecologic sources is a common problem in surgery. The etiology of this pain in reproductive age females is often obscure (5). Many of these gynecologic sources of acute abdominal pain can be managed laparoscopically. Laparoscopy is indicated when the diagnosis is uncertain, the patient is obese, and the definitive operative management can be handled with the laparoscopic technique. The only contraindication is the patient with hemorrhagic shock.

Another cause of acute abdomen can be the acute pancreatitis. The laparoscopic diagnosis is made by opening the lesser sac with scissors dissection.

Ischemic bowel can be found at laparoscopy for an acute abdomen. It depends on the judgment of the surgeon to determine if it is hopeless situation (6). If the bowel is ischemic and not necrotic, the patient should have emergency mesenteric angiography.

The use of laparoscopy in blunt abdominal trauma has been expanded from merely a diagnostic tool to a therapeutic modality in selected cases (7). This has resulted in a quicker and more specific diagnosis and avoidance of unnecessary laparotomies.

Regarding the outcome measures for cases of the acute abdomen as a whole, Agresta *et al.* (8) included 1,272 patients admitted with acute abdomen who were approached laparoscopically. In comparison with open surgery, there was a significant reduction of total complication in laparoscopic treatment than open surgery (1.9 *vs.*13%).

Hemodynamic instability, huge abdominal distension, fecal peritonitis, and perforated cancer are relative contraindications for the laparoscopic approach. In recent years, abdominal emergencies have increasingly been managed successfully by laparoscopy. In acute appendicitis, acute cholecystitis and perforated peptic ulcer, randomized controlled trials have proven that the laparoscopic approach is as safe and as effective as open surgery, with fewer complications and a quicker postoperative recovery. Other indications such as blunt and penetrating trauma to the abdomen, small bowel occlusion and perforated diverticular disease are under debate, indicating that more randomized controlled trials comparing laparoscopic and open surgery are still necessary (6).

CONCLUSIONS

Laparoscopy is very important in the diagnosis and treatment of acute abdomen conditions. This is due to certain advantages as the ability to examine the entire peritoneal cavity and perform a definitive procedure, and of course when needed there is always the possibility to convert to an open procedure. Laparoscopy also reduces unnecessary laparotomies.

LONG TERM CONTROL IN ACROMEGALY - IS IT ACHIEVABLE?

Acromegaly is a rare endocrine disorder characterized by an excessive chronic secretion of GH and IGF-I, that, in time, results in numerous comorbidities. Biochemical control is not easily achievable but is of paramount importance for a reduction in morbidity and mortality. The presented results come from an extension to a prospective, multicenter, randomized, parallel-group, 6-month core study (Phase III PAOLA study). In the core study, patients were randomized to double-blind long-acting pasireotide 40 mg/28 days or 60 mg/28 days, or continued treatment with open-label long-acting octreotide 30 mg or lanreotide 120 mg every 28 days. As much as half of the enrolled patients had at least three comorbidities (mostly cardiovascular and glucose- or lipid-related disorders) at study entry. The conclusion of this study is that long-acting pasireotide was an effective and consistent therapeutic option for up to 5.8 years of treatment in patients with previously uncontrolled acromegaly and a high prevalence of comorbidities (cardiovascular, metabolic, including glucose-related disorders). (Colao A, Bronstein MD, Brue T, *et al*. Pasireotide for acromegaly: long-term outcomes from an extension to the Phase III PAOLA study. *Europ J Endocrinol* 2020; 182(6): 583-594).

DILEMMAS AROUND NECROTIZING ENTEROCOLITIS IN LATE PRETERM NEONATES

DILEMMAS AROUND NECROTIZING ENTEROCOLITIS IN LATE PRETERM NEONATES (Abstract): Necrotizing enterocolitis is an acquired, multifactorial, and potentially severe gastrointestinal disease characterized by ischemia, necrosis, and inflammation of the bowel wall. It affects mostly very low birth weight preterm neonates, but approximately 10% of the cases are diagnosed in late preterm and term infants with risk factors for mesenteric ischemia like intrauterine growth restriction, polycythemia, birth asphyxia, chorioamnionitis, sepsis, or congenital gastro-intestinal or cardiac defects. In growth restricted newborns the incidence of necrotizing enterocolitis is approximately twice compared to those with adequate birth weight. In these fetuses blood flow to the brain is preserved at the expense of blood flow to other organs, including the gastrointestinal tract, which leads to mesenteric ischemia. An exclusive human milk diet might be protective due to growth factors, antibodies, cellular immune factors, probiotic bacteria, oligosaccharides, and stem cells, which are all present in fresh breastmilk. **Keywords**: NECROTIZING ENTEROCOLITIS, IUGR, CONGENITAL CARDIAC DEFECT, LATE PRETERM.

Necrotizing enterocolitis (NEC) is an acquired, multifactorial, and potentially severe gastrointestinal disease characterized by ischemia, necrosis and inflammation of the bowel wall. Being one of the most common neonatal gastrointestinal emergencies requiring surgery, this disease presents high mortality rate (10-30%), particularly among preterm infants (1,2). While some studies claim that the incidence of NEC remained stable in recent years (~10%) (3, 4), different studies revealed that due to the enhanced survival of extremely low birth weight (ELBW) newborns, the incidence has increased (11-15%) (5-7).

The risk of developing NEC depends on the gestational age (GA), the lower the GA, the higher the risk (8). For the survivors affected by NEC, there is high associated morbidity with neurodevelopmental sequelae and retinopathy of prematurity (2). Being one of the main causes of mortality and morbidity in neonatal intensive care unit (NICU), a better understanding of the pathogenesis of NEC is critical in order to

have an early diagnosis. Very low birth weight (VLBW) preterm infants represent the vast majority of patients affected by NEC, however about 10% of the cases are diagnosed in late preterm and term infants with risk factors for mesenteric ischemia like intrauterine growth restriction (IUGR), polycythemia, birth asphyxia, chorioamnionitis, sepsis, or congenital gastrointestinal or cardiac defects (9-12). The risk factors for different etiopathogenetic mechanisms of NEC, as well as most common laboratory and radiological findings are summarized in (tab. I).

TABLE I

Risk factors for different etiopathogenetic mechanisms of NEC and common laboratory and radiological findings.

	ISCHEMIC NEC	**INFECTIOUS NEC**
Medical history	Full-term/late preterm infant with IUGR Caesarean section 5-minute Apgar score < 7 Severe metabolic acidosis Hypoglycemia Severe anemia/ polycythemia 36ºC at 1 hr. of life Mother with preeclampsia or diabetes Placental abruption Gastroschisis/omphalocele Congenital heart disease (patent ductus arteriosus, hypoplastic left heart syndrome etc.) (13) Umbilical arterial catheterization (14)	Preterm infants (< 32 weeks GA) VLBW infants (< 1,500 g) Chorioamnionitis Premature rupture of membranes
Drugs	Indomethacin ± dexamethasone Ibuprofen Red blood cell transfusions (15)	H2 blocker (ranitidine/famotidine/nizatidine) (16,17) Empirical antimicrobials
Time of onset	Short term after birth (5.3 days) (11)	Later onset (15.3 days) (11)
Laboratory studies	• Blood culture negative • Negative gastric aspirate • Normal WBC • Low serum bicarbonate (due to poor tissue perfusion - isolated, without metabolic acidosis) • Inflammatory syndrome is absent - normal serial CRP values would favor aborted antibiotic therapy and early resumption of feedings (18).	• Blood culture may be positive in sepsis • Gastric aspirate may be positive (a negative gastric aspirate does not exclude a bacterial infection) • Inflammatory syndrome present -persistently elevated CRP after initiation of appropriate medical management suggests associated complications (18). Moderate to profound neutropenia - sepsis • Low hematocrit or hemoglobin may suggest infection or are low due to blood loses caused by consumptive coagulopathy • Low serum bicarbonate (associated with severe metabolic acidosis in sepsis) • Thrombocytopenia - reaction to gram-negative organisms and endotoxins or as part of consumptive coagulopathy (associated with high levels of PDF) • Fecal volatile organic compounds (VOCs) (19)

	ISCHEMIC NEC	INFECTIOUS NEC
Radiography	• Abnormal gas pattern • Dilated bowl loops • Thickened bowel walls	Radiological signs from ischemic NEC associated with: • Pneumatosis intestinalis • Portal venous gas • Abnormal free air • Intraperitoneal free fluid

CASE REPORT

Prenatal and birth history

Preterm female infant, GA 34 weeks, birth weight 1,800 g, first twin, of a dichorionic diamniotic pregnancy, born vaginally in a level II maternity to a 20 year old mother with inadequate prenatal care. In the last month of pregnancy, the mother had a urinary tract infection with *Escherichia coli* treated with antibiotic (Cefiximum). Apgar scores were of 8/9/9 at 1, 5 and 10 minutes, requiring early CPAP in the delivery room for 15 minutes.

The second twin was also female, with a BW = 2150 g, and Apgar scores of 9 at 1 minute and 10 at 5 minutes. Twin 2 had an uncomplicated course in the neonatal intensive care unit.

Hospitalization course prior to transport

The infant was admitted in the level II NICU at 20 minutes of life and the initial physical exam revealed intercostal and subcostal retractions, oxygen saturation (SpO_2) of 88%, a heart rate (HR) of 135 beats/minute (bpm), respiratory rate of 38 beats/minute and blood pressure (BP) 63/24/35 mmHg. The neonate required free-flow oxygen in order to maintain SpO_2 within normal range, parenteral nutrition, and prophylactic antibiotic (Ampicillin). Enteral feeding was initiated with formula on day of life (DOL) 2.

Initial laboratory studies revealed hemoglobin (Hb), hematocrit (Ht) white blood cell count (WBC) within normal range, negative C-reactive protein (CRP) and initial peripheral cultures (skin, external auditory canal, gastric liquid, and nasopharyngeal swabs).

On the fifth day of life the patient became unstable and clinical examination revealed recurrent desaturations (lowest value of SpO_2 = 50%) and coffee ground followed up by bilious emesis. Blood gas analysis showed mild respiratory acidosis (pH 7.26 and PCO_2 52.7 mmHg). Chest and abdomen X-Ray was normal. Blood and stool were sampled for bacterial cultures (and were negative after 72 hours). Feeds were stopped and ampicillin was replaced by intravenous gentamicin and colistin. At this point then transfer to level III center was requested. During transfer the neonate was stable with free flow oxygen.

Neonatal course at level III facility

The clinical examination at admission in the level III ICU revealed pale-greenish skin, hypotonia, shallow breathing, systolic murmur grade IV/VI, tachycardia (175-181 bpm) and bilious drainage with streaks of old blood. Immediately after admission, she presented severe recurring apneas requiring positive pressure ventilation (PPV) followed by intubation and mechanical ventilation (SIMV). Blood gas analysis showed respiratory acidosis with normal oxygenation (pH = 7.26, PCO_2 = 52.8

mmHg, PO_2 = 58 mmHg). Laboratory workup on admission revealed anemia, leucopenia (I/T = 0.47), elevated CRP and PCT (tab. II).

The X-Ray on admission revealed distended bowels with wall edema. Peripheral and blood cultures, as well as cerebrospinal fluid were collected.

TABLE II

Laboratory workup on admission and during hospitalization in the level III NICU up to DOL 17

Day of Life (DOL)	Hb (g/dl)	Ht (%)	WBC x10^3/mm^3	PLT x10^3/mm^3	CRP	PCT	Direct bilirubin	Urea
6	10.6	33.2	2.8	187	44.1	20.7	0	69.8
8	13	41.1	6.7	104	50.6	6.86	0.2	110.7
9	10.1*	31*						
10	12	37.9	9.8	120	125.2	1.06	0.4	66.3
14	10.6	33.1	17.9	249	87.5	1.11	1.4	79.5
17	14.3	43.7	16.3	174	37.6	0.79	0.9	71
*values from the arterial blood gas bulletin								

A nasogastric tube was placed for decompression of the dilated bowels and total parenteral nutrition (TPN) and intravenous antibiotics with broad-spectrum coverage (colistin, meropenem and gentamicin) were started. The cranial ultrasound revealed supernumerary ventricular cavity. Echocardiography showed Tetralogy of Fallot (TOF) with mild pulmonary stenosis, *patent foramen ovalae* and *ductus arteriosus*. Blood cultures and lumbar puncture were negative, and the peripheral cultures were positive for *Escherichia coli*. The newborn required mechanical ventilation for 21 days, three packed RBC's transfusions (15 ml/kg) for anemia and completed a 15-day course of antibiotic therapy for presumptive sepsis despite negative blood culture. Following treatment, clinical status improved slowly, and the laboratory tests normalized by DOL 17. Enteral feeds were restarted on DOL 15 with full feeding established on DOL 29.

Onward the clinical course of the infant was uneventful, however on DOL 55 the neonate presented marked abdominal distension and the X-ray revealed dilated intestinal loops. Following surgical consult, the newborn was transferred to the pediatric surgery department for further evaluation.

DISCUSSION

The etiology of NEC is not entirely understood as multiple factors appear to be involved, including hypoxia, acidosis, and hypotension, leading to ischemic damage of the mucosal barrier of the small intestine. Gram negative bacterial invasion of the mucosa may be another factor involved in the pathogenesis of NEC. Repeated radiographs are recommended, pneumatosis intestinalis and portal venous gas being pathognomonic signs, caused by anaerobic

bacteria, particularly by Clostridia.

Newborns with very low birth weight (< 1,500 g) and very preterm infants (< 32 weeks) are the most affected by this pathology (3, 20), as they have decreased ability to suppress the exaggerated inflammatory response or are unable to develop an inflammatory response to pathogenic bacteria (21). This case report presents a late preterm infant with a low birth weight and congenital heart disease. Hence, intestine mucosal injury and ischemia might have played a part in the development of NEC.

The signs and symptoms of necrotizing enterocolitis are highly variable, nonspecific and subtle (22). Physical examination findings may include abdominal distention, abdominal tenderness, visible intestinal loops, decreased bowel sounds, palpable abdominal mass, and erythema of the abdominal wall. Systemic findings may include respiratory failure, circulatory collapse, and decreased peripheral perfusion. The clinical course of this patient was marked by multiple days of parenteral nutrition and mechanical ventilation.

The role of inflammation in the pathogenesis of NEC is increasingly recognized. Antenatal inflammatory processes like chorioamnionitis may increase the susceptibility of preterm infants to develop NEC. Decreased intestinal mucosal thickness and increased mucosal permeability, as a result of inflammatory mediators, may explain this association (21). This twin derived from a mother with urinary tract infection in the third trimester, which seems to have complicated the course of the disease.

A recent meta-analysis investigating the outcomes of preterm infants affected by IUGR compared with those without growth restriction found that the incidence of NEC was at least 2.5 times higher in preterm infants with growth restriction (22). It is suggested that in such fetuses, blood flow to the brain is preserved at the expense of blood flow to other organs, including the gastrointestinal tract (23). Although the evidence suggests that newborns with IUGR and abnormal antenatal Doppler are at increased risk of developing NEC, early initiation of breast milk feeds does not appear to increase the incidence of NEC in this population (23).

Generally, this condition occurs after the first week post-partum when the intestine has been colonized (24). In this case, rapid initiation of enteral feeding with formula was a risk factor for NEC, due to changes in enteric blood flow and oxygen requirements during feeding. An exclusive human milk diet might be protective due to growth factors, antibodies, cellular immune factors, probiotic bacteria, oligosaccharides, and stem cells. Fresh maternal breast milk is superior to frozen or donor breast milk (25, 26). A prospective multicenter study concluded that the incidence of NEC was 6-10 times higher in exclusively formula-fed infants when compared with exclusively breast milk-fed newborns, and three times higher when compared with infants who received breast milk and formula (27). Early initiation of enteral feeds in preterm infants with very small non-nutritive volumes (known as trophic feeding or minimal enteral nutrition) is thought to have several advantages over complete fasting as a result of “priming” the gastrointestinal tract and aiding in its maturation processes (28-30). Initially, one of the differential diagnosis considered was feeding intolerance caused by lactose intoler-

ance. Neonatal lactose intolerance syndrome is based on a series of digestive system symptoms caused by the lack of lactase, leading to the inability of digesting the lactose in breast milk or cow milk. Symptoms of lactose intolerance include loose stools, abdominal bloating and pain, flatulence and vomiting (31). In this particular case, the neonate presented gastric residuals, abdominal tenderness, and recurrent apnea/bradycardia, which together with the systemic signs and abnormal blood work raised the suspicion of sepsis.

The reported frequency of NEC in infants with critical congenital heart disease (CCHD) ranges from 3% to 9% (32-35) with no relationship to feeding practices. However, in many centers infants with CCHD are managed with TPN and enteral feedings are deferred in the preoperative period (36, 37) as hypoxia, poor mesenteric perfusion, acidosis and hemodynamic instability are high risk factors for NEC. In our case the diagnosis of congenital heart defect was made on DOL 7, after the onset of symptoms and the deterioration of the infants' clinical status. TOF with mild pulmonary stenosis is unlikely to be a risk factor for NEC, but in this particular case it might have played a part in the intrauterine growth restriction, considering the fact that the other twin without cardiac pathology had an adequate birth weight and an uneventful clinical course. The growth restricted twin was at risk for both NEC and sepsis, making the differential diagnosis extremely challenging, as clinical signs are frequently non-specific and overlapped and laboratory test results may show similar abnormalities. However, the medical treatment in both cases follows the same general principles. The suggested antibiotic regimen includes ampicillin, gentamicin, and either clindamycin or metronidazole. While the patient is NPO, total parenteral nutrition must be provided. Antimicrobial therapy should always be adapted to the pathogen causing the disease. It is recommended to be justified by clinical, paraclinical and imagistic arguments in order to prevent bacterial antibiotic resistance.

If this conservative therapy is effective, infants may resume enteral feedings once signs of infection or abdominal pathology have disappeared. In some cases, this may take several days to a week. The presence of normal bowel movements suggests the return of bowel function. In infants with confirmed NEC who have worsening condition or bowel perforation or who do not respond to medical therapy, surgical intervention is indicated. Laparotomy is the standard approach, surgery being as conservative as possible, with removal only of portions of unquestionably necrotic or perforated intestine in an attempt to preserve as much intestine as possible (38).

For the neonatologist, the decision to refer the case to the pediatric surgeon and the timing of the referral are real challenges when faced with a neonatal patient with clinical deterioration despite maximal medical therapy, in the absence of free air in the abdominal cavity, as in the present case.

CONCLUSIONS

The peculiarity of this case consists in the association of multiple risk factors, as well as several etiological contexts - ischemic and infectious - which make inclusion into classical etiopathogenetic mechanistic patterns extremely difficult, if not impossible.

SMALL BOWEL ADENOCARCINOMA ARISING IN LONGSTANDING FIBROSTENOTIC CROHN'S DISEASE (Abstract): Empirical evidence suggesting a link between neoplasia and chronic inflammation was first noted by Virchow more than a century ago, but the intricacies of the involved pathological processes have not yet been entirely elucidated. With a growing number of Crohn's disease (CD) cases worldwide, it is only logical to consider that the complications of this entity would become proportionally more prevalent. We report a case of small bowel adenocarcinoma arising in a patient with longstanding CD and discuss the current differences in paradigms related to surgical decisions in patients with inflammatory small bowel disease. A 56-years-old male patient known with CD was admitted in emergency to our clinic for intense diffuse abdominal pain spontaneously and on palpation, Blumberg +, with signs of peritoneal irritation, episode apparently much more severe compared to the previous ones. Laboratory investigations confirmed the diagnosis of acute abdomen and immediate surgery was performed. Intraoperative findings were peritonitis due to ileal perforation and ileal adenocarcinoma with "signet ring" cells, moderately differentiated (G2), on the background of active inflammatory bowel disease (CD). Segmental enterectomy and ileostomy were performed. The postoperative outcome was relatively favorable, with resumption of digestive tolerance and of intestinal transit at ileostomy level. As increased evidence suggest causality between chronic inflammation and malignant transformation one should contemplate whether the old treatment paradigms applied for other conditions such as fistulae in anal and leg ulcers should not be translated to inflammatory bowel disease (IBD) patients. Are we doing too much or not enough surgery for IBD? Could we diagnose small bowel adenocarcinomas in CD in early stages or there is too much risk for the patients and very few to benefit from a more aggressive surveillance? **Keywords:** CHRON'S DISEASE, SMALL BOWELL ADENOCARCINOMA, EMERGENCY SURGERY, ILEOSTOMY.

Empirical evidence suggesting a link between neoplasia and chronic inflammation was first noted by Virchow more than a century ago but the intricacies of the involved pathological processes have not yet been entirely elucidated (1). Many types of cancers arise at sites with chronic inflammation, such as Marjolijn ulcers in

longstanding venous insufficiency, anal carcinomas in chronic fistulae or gastroesophageal tumors promoted by gastroesophageal reflux disease (GORD) and Barret's esophagus. Dr. Burrill Crohn described the eponymic disease in 1932 but the first case of small bowel adenocarcinoma in an IBD patient was reported in 1957 by Ginzburg.

The growing number of CD cases worldwide justifies us to believe that the complications of this entity would become proportionally more prevalent. Thus, emphasizing their existence by reporting unusual or rare cases would increase the awareness on epiphenomena and peculiar manifestations associated with IBD.

CD, a chronic inflammatory disease located in the wall of the digestive tract, can theoretically affect any segment from the esophagus to the anus, but especially the distal portion of the small intestine (terminal ileitis) and the colon. It is characterized by transmural ulcerative lesions that can cause complications such as strictures or fistulas. It is a disease that affects young people (15-30 years) but can also occur in children (2) or older ages, with equal incidence in women and men. CD is also associated with many extraintestinal manifestations, most triggered by an autoimmune mechanism, little elucidated.

The main manifestations of CD are accentuation of intestinal transit - stools several times per day – persistent over weeks or months (noninfectious chronic diarrhea), recurrent abdominal pain, rectal bleeding, persistent fever, impaired general condition, weight loss. The spread of inflammatory bowel disease together with severe diarrhea may require emergency hospitalization. Sometimes the symptoms resemble acute appendicitis or intestinal obstruction, usually the patients being hospitalized to determine the cause of prolonged diarrhea or persistent febrile syndrome or because they are frightened by rectal bleeding. Most often, CD is a chronic disease with remissions lasting for weeks or years, interspersed with severe exacerbations.

The positive diagnosis is suggested by the above-mentioned symptoms, helped by the presence of the biological inflammatory syndrome (increase in ESR, fibrinogen, C-reactive protein), possibly anemia and it is confirmed by digestive endoscopy (diffuse, discontinuous mucosal involvement, with linear and deep ulcerations; histopathological evidence of deep chronic lymphoplasmacytic infiltrate, based on glandular crypts, architectural distortions of the gastric mucosa, presence of sarcoid-like granulomas, and transmural damage to the intestinal wall).

Complications of CD can be parietal and perianal abscesses, fistulas: enter enteric, enter vesical, enter vaginal, enterocutaneous, with infectious complications caused by the septic content of the intestine, adhesions of the neighboring intestinal loops with the development of tumor masses with obstructive phenomena, toxic dilation of the colon (toxic megacolon) - rare - with imminent danger of perforation, anemia, malnutrition, malignancy (3).

CD is treated with medicines, surgery being usually considered in case of complications (fistula, abscess, occlusion, and tight stenosis, especially in the small intestine). The drugs used address the inflammatory substrate (anti-inflammatory agents: sulfasalazine, corticotherapy) and also immunosuppressants: azathioprine, mercaptopurine, methotrexate, cyclosporine).

The prognosis of CD is variable, depending on the extent of the inflammatory process, presence of complications, treatment followed, and last but not least, patient's compliance; being a chronic disease

it requires regular medical investigations, careful and competent follow-up (4). Fortunately, malignant degeneration is a rather rare complication, its incidence increasing after 10 years of active disease, but with a more unfavorable prognosis.

CASE REPORT

A 64-year-old male patient, known with Crohn disease, diagnosed 3 years earlier in the gastroenterology service, on treatment with sulfasalazine, with repeated sub occlusive episodes, regular hospitalizations in the surgery service, in imminent surgery, successfully timed each time. He presents to the emergency room complaining of significant abdominal pain, accompanied by nausea and vomiting, intestinal transit disorders, initially diarrheal stools, then no stool in the last 48 hours, symptoms progressively accentuated in the last 12 hours. Clinical examination revealed altered general condition, psychomotor agitation, cachexia, pale skin and mucous membranes, BP 110/55 mmHg, AV 88/min. Local abdominal assessment revealed: intense diffuse abdominal pain spontaneously and on palpation, Blumberg +, with signs of peritoneal irritation, episode apparently much more severe compared to the previous one. Biological samples showed leukocytosis (WBS 27,000/uL), moderate anemia (Hg 10 g/dL).

Fig. 1. Pneumoperitoneum, CT image.

Fig. 2. CT images: at the level of the distal small bowel, ileocecal valve, descending colon, and sigmoid, distended intestinal loops, with edematous, thickened circumferential wall; free fluid in medium-large quantity, perihepatic, peri splenic, inter-ileal, parieto-colic and at the pelvic level.

Emergency CT scan showed bilateral subdiaphragmatic pneumoperitoneum (fig. 1), medium-large amount of free fluid at perihepatic, peri splenic, interileal, paracolic and pelvic level, multiple lymphadenopathies with the highest diameter 18/16 mm projected in the hepatic hilum, interaortocaval, lumboaortic regions, bilateral mesenteric and external iliac roots. The intestinal loops are distended and with edematous thickened wall, suggestive of inflammation/ intraperitoneal infection (fig. 2).

Clinical-laboratory investigations confirmed the suspicion of acute abdomen, surgery being the next step. The signed informed consent was obtained after discussing with the patient the probability of a temporary ileostomy, and the possibility of malignancy. The disclosure included the possible medical errors and therapeutic alternatives in a comprehensive information and transparency of the medical attitude (5). Thus, under general anesthesia, immediate surgery was performed. Intraoperatively, generalized peritonitis with multiple abscesses and entero-enteral fistulas of the terminal ileum, as well as a hard tumor mass at the level of ileum, located at about 20 cm from the ileocecal valve were found. Segmental enterectomy (approximately 50 cm) was performed with terminal ileostomy, abundant peritoneal lavage, and multiple peritoneal drainage. The segmental enterectomy specimen had a diameter ranging between 2 and 4.5 cm, which presented at 17 cm from the distal resection edge a 2.5 cm perforation area and multiple micro abscesses in the serosa. At sectioning, the intestinal wall was diffusely thickened (up to 0.8 mm), the mucosa showing atrophic folds, with areas of ulceration alternating with areas with whitish-green deposits; towards the distal edge of the resection the intestinal lumen was stenotic.

The resection specimens were sent for histopathological examination at the pathology department of the same hospital. These were fixed in 10% buffered formalin for 24 hours and processed according to the classical histopathological technique (hematoxylin eosin staining).

Although the macroscopic appearance suggested rather a stenotic area in the intestinal wall, a common lesion found in patients with CD, microscopic examination revealed the presence of an invasive malignant tumor with glandular differentiation that penetrated circumferentially and diffusely the whole intestinal wall, reaching the level of the serosa, and extending to the sub serosal space (fig. 3).

Tumor cells were pleomorphic, with marked cytonuclear atypia and relatively common mitotic figures. Tumor mass present also a part of weakly cohesive tumor cells with the classic appearance of “signet ring” cells (figs. 4 and 5).

In addition to the presence of tumor proliferation, the remaining intestinal wall showed histopathological changes suggestive of active CD: deep erosions of the intestinal mucosa, villoglandular destruction, extensive foci of pseudo pyloric metaplasia, areas of fibrosis, sarcoid-like granulomas located deep in the intestinal wall and even in the vicinity of tumor contingent, marked interstitial edema of the lamina propria and marked basal plasmacytosis (figs. 6, 7, 8). Twenty-five locoregional lymph nodes were identified and evaluated (hematoxylin eosin staining), of which 9 shows tumor invasion (pN1)–lymph node metastasis with cells in the “signet cells” (fig. 6). Adjacent to the glandular tumor

proliferation, desmoplastic reagents were identified in the context in which there were predominantly chronic lympho-plasmacytic inflammatory infiltrates and discoid "signet cells" (10% of tumor mass). Also, the intestinal wall presented a deep ulceration that affected the entire intestinal wall.

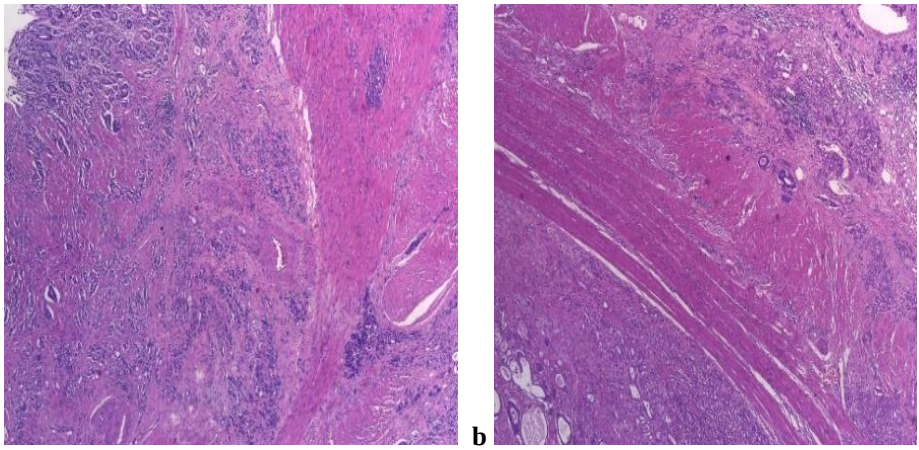

Fig. 3. (a, b). Small bowel adenocarcinoma infiltrating the full thickness of the muscularis propria with massive extension to the subserosa space. (Hematoxylin and eosin staining, ob. 4X)

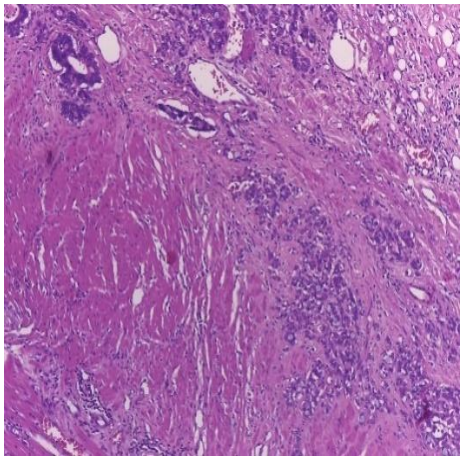

Fig. 4. Small bowel adenocarcinoma showing a mixture of poorly cohesive signet ring cell and glandular structures, with lymphovascular invasion. (Hematoxylin and eosin staining, ob. 10X)

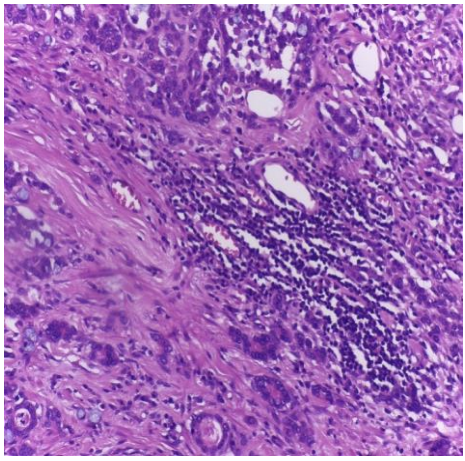

Fig. 5. Tumor cells with predominant signet ring cell features discohesively infiltrating the muscularis propria. They have hyperchromatic nuclei with moderate cytologic atypia. Chronic inflammatory cells (lymphocytes and plasma cells) are also present (Hematoxylin and eosin staining, ob. 20X).

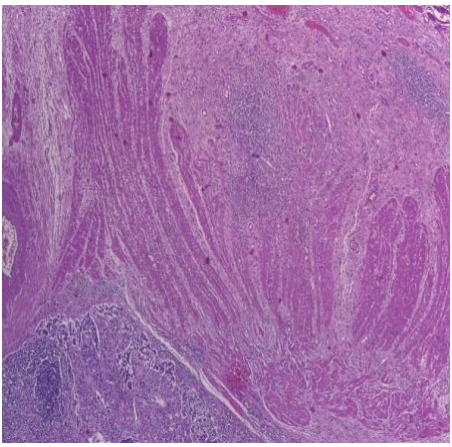

Fig. 6. Small bowel adenocarcinoma in CD. Note the marked distortion of the muscularis propria by fibrosis and transmural inflammation with lymphoid aggregates, sarcoid-like, noncaseating and poorly formed granulomas. (Hematoxylin and eosin staining, ob. 4X)

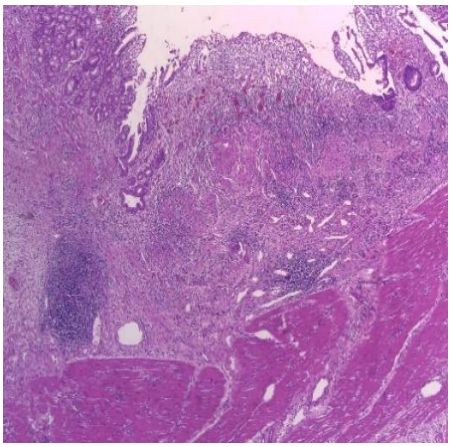

Fig. 7. The remaining intestinal wall had the typical appearance for CD: superficial and deep ulceration with adjacent granulation tissue extending into deep submucosa, lymphoid aggregates, and poorly formed granulomas, fibrosis, and edema of the lamina propria and muscularis propria, reduplication of the muscularis mucosae, and pseudo pyloric metaplasia. (Hematoxylin and eosin staining, ob. 4X).

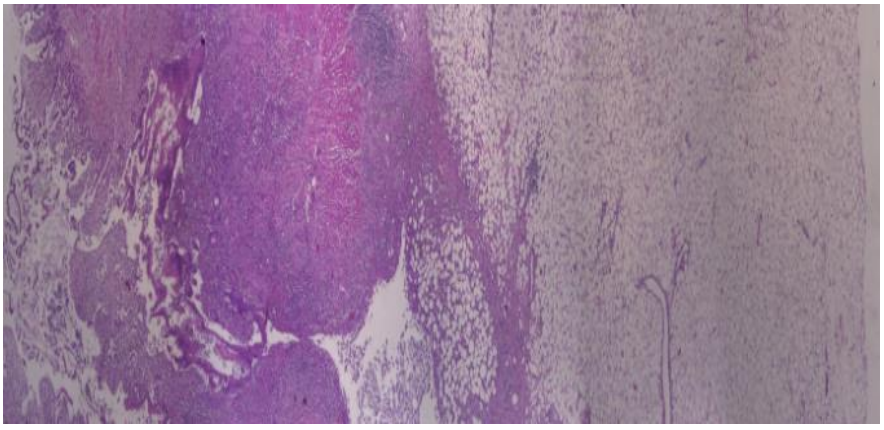

Fig. 8. Deep transmural ulceration of the small bowel wall. Image edited and stitched using Leica imaging software (Hematoxylin and eosin staining, ob. 4X).

The final histopathological diagnosis was intestinal (ileal) adenocarcinoma with the component of moderately differentiated (G2) signet-ring cell carcinoma arising in the setting of active inflammatory bowel disease (CD) - pTNM: pT4pN1Mx (stage IIIA). The advanced neoplasia was an intraoperative finding, during emergency

surgery for acute abdomen and peritonitis caused by ileal perforation.

The patient had a relatively favorable postoperative outcome, with resumption of digestive tolerance and intestinal transit at the level of ileostomy. He was referred to the Oncology Department for postoperative adjuvant chemotherapy.

DISCUSSION

IBDs are lifelong conditions with an individual pattern of flares and remission periods and with permanent potential of complications. Although both ulcerative colitis (UC) and CD (CD) share an immune mediated chronic inflammation, the propensity for malignant transformation and perforations differ considerably (6). UC is not a transmural disease; hence it does not produce strictures or perforations, but it does cause bowel cancer in 20% percent of the patients after 30 years of active disease. CD is notorious for fibro stenotic changes of the bowel, but it rarely elicits malignant transformation. (7) Some studies have shown that the risk of small bowel adenocarcinoma is increased by more than 60-fold in patients with IBD as compared to general population (8). In a meta-analysis by von Roon *et al.*, the relative risk of developing small bowel carcinoma in 9642 patients was estimated at 28.37, and the incidence rate of small bowel carcinoma in 12,740 patients was 15 per 100,000 patient years (9). However, the exact magnitude of the increased risk is hard to establish because data derived from population-based studies, case-controlled studies, physician surveys, and case reports have been combined in most studies regarding the incidence of malignancy in patients with IBD. In the same review by von Roon *et al.*, the mean duration of Crohn's disease before the onset of malignancy was about 9 years. The relative risk of developing small bowel carcinoma compared to the background population was higher in North America (RR = 41.23), the United Kingdom (RR = 40) and Scandinavia (RR = 21.3). The vast majority of patients with IBD-induced small bowel cancers have endured a long course of the disease raising the question whether a more thorough surveillance for malignancies might increase early detection and survival in these patients (10). With regard to perforating complications of CD there is strong evidence that deferring surgery is a helpful strategy in avoiding short bowel syndrome and multiple surgeries related sequels. There is growing evidence that a large array of cytokines, such as interleukins (IL-6, Il-10, Il-22, Il-26), LBP, soluble CD14 receptor plays a crucial part in the uncontrolled intestinal inflammatory process, which is a main characteristic of IBD. Additional testing of inflammatory biomarkers such as Il-6 and LBP could be a useful tool for monitoring the severity of inflammation, but also the onset of a septic intraperitoneal complication (11,12). Acute abdomen due to ileal perforation is a serious, life threating condition. Ileocolic perforation might be favored by stenotic lesions, with upstream dilatation, fistulizing disease, or carcinoma. Emergency surgery is particularly vulnerable to patient safety issues, due to short time of planning and difficulties related to preoperatory investigations and risk assessment (13). The coexistence of pathological associations in emergency supports the need for a thorough intraoperative examination to address to all lesions (14). The use of the laparoscopic approach also in case of diffuse peritonitis is now becoming accepted provided hemodynamic stability and may be

used successfully even in perforation associated with Crohn disease, ensuring a faster recovery and shorter hospital stay (15, 16). In patients with associated malignancy, some authors recommend that the opportunity of primary anastomosis and bypass protection should be judged individually, upon the patient's clinical condition and past history of steroid use. However, when malignancy and perforation are associated, anastomosis is not recommended, being associated with high morbidity and mortality (17-20). Careful examination of the vascularization of anastomosis tranches is important to prevent anastomosis leaks, one of the most frequent causes of postoperative morbidity (21).

Patients with CD are at increased risk of colorectal cancer and a higher mortality from colorectal cancer in comparison with general population (22). Strong *et al.* (23) recommend total proctocolectomy in the surgical management of CD-associated malignancy in cases with high grade dysplasia or multifocal low-grade dysplasia. Several clinical studies documented the high rate (35-40%) of metachronous cancers following segmental or subtotal colectomies (23-25). In the present paper, a less invasive approach was chosen due to the general condition of the patient and the presence of intense peritoneal cavity contamination. According to Ola *et al.* (22), a careful colorectal cancer surveillance was indicated especially in patients diagnosed with CD before the age of 40 years, patients with colon inflammation, and in those who have primary sclerosing cholangitis.

CONCLUSIONS

A high level of suspicion and awareness of malignant transformation in CD is key to early diagnosis. Better outcomes in patients with small bowel adenocarcinoma arising in IBD strictures would be expected with advancements in radiology and refinement of surveillance guidelines. CD remains a condition with a high rate of both benign and malignant transformation.

Further studies on the sequence of metaplasia-dysplasia-cancer in IBDs would bring more evidence to explain the differences between UC and CD in terms of malignant potential and would provide a solid background for improved surveillance guidelines.

CONFLICT OF INTERESTS AND FUNDING

The authors declare that there is no conflict of interest and they received no specific funding regarding this scientific research.

VARIABLES INFLUENCING MEDICAL DECISIONS IN A CLINICAL REHABILITATION HOSPITAL (Abstract): The discharge from the hospital represents a complex process that should assess the patient's ability to adapt outside of the medical setting. **Material and methods:** This paper analyses the medical status of the patients admitted to a rehabilitation clinic, at the moment of discharge, considering a number of influencing factors, such as age, sex, place of origin, length of stay (LOS) in the hospital. In order to achieve this purpose, we conducted a study on 136 patients discharged from the Clinical Rehabilitation Hospital Iasi in 2016 using an econometric modelling. **Results:** Our findings reveal that the medical status of the patients at the time of discharge was not influenced by the sex or place of origin. Also, with an increase in patient's age by one year, the estimated chances of a patient not to be cured at discharge decreases by 3.5%. In addition, with an increase in the patient's length of stay in the hospital by one day, the estimated chances of a patient not being cured at discharge time increases by 8.1%. **Conclusions:** It was found that the age and the length of admission in the hospital has a significant influence on the disease stabilization, even if the patients are not fully cured at discharge time. Because the research only considered data from a single regional hospital, it limits the conclusions that can be drawn from the sample. **Keywords:** MEDICAL STATUS, DISCHARGE, ECONOMETRIC MODELING, LENGTH OF STAY.

Managers put forth significant effort to make acceptable organizational decisions, hence decisions and decision-making processes are at the heart of management (1, 2). Because the efficacy of corporate activities is primarily determined by how decisions are created and implemented, the study of decision-making processes is becoming increasingly essential (3, 4), because decisions affect not only the organization in which they are made, but also the people who work there (5, 6).

Clinical decision-making is at the heart of clinical practice on a daily basis. The application of clinical and biomedical information, problem-solving, calculating probability and possible outcomes, and risk-benefit balance are all part of this

process. One of the most difficult tasks is to strike a balance between personal experience and general knowledge (7).

MATERIAL AND METHODS

The goal of our research was to determine the elements that influence decision-making and the parts actively involved in the process. Taking a careful look at the literature, we can observe that the socio-economic status of our country is crucial, independent of the decisional model adopted.

This paper investigates whether the medical state of patients at discharge is influenced by their age, place of origin, gender, and the LOS in the hospital. Patients hospitalized to the Clinical Rehabilitation Hospital from Iasi, in 2016 constitute up the study population. A total of 136 patients were randomly chosen from the population. The analysis did not contain any clinical data from the patients. The *SPSS* statistical analysis tool was used to process the sample data.

The variables considered in this study were: LOS, place of origin, age, gender, and medical condition at discharge. The study-dependent variable, namely the medical condition of the patient at discharge, is a nominal qualitative variable with two categories: cured and not cured. The independent variables considered in the analysis were divided into continuous quantitative variables (age and LOS) and nominal or qualitative variables (gender and place of origin). Both gender and place of origin variables have two categories: female and male, respectively rural and urban.

Statistical analysis

For the qualitative independent variables, the patient distribution was analyzed by calculating the absolute and relative frequencies. Also, the average percentages for each of these variables were calculated. *Pearson Chi-square* test was used to determine the association between the dependent variable and each of the qualitative independent variables.

The econometric modelling was conducted with logistic regression to determine the link between the medical status of the patient and the independent variables (age, gender, place of origin, and LOS), using as statistical analysis *Pearson Chi-square test*, relative frequencies, assumed risk, probabilities, relative risk, odds and odds ratio.

RESULTS

Patients distribution using qualitative variables

The absolute and relative frequencies of the qualitative characteristics were determined for a full investigation of the patients' distribution. Out of a total of 136 patients, 68 (50%) were cured at the time of discharge and 68 (50%) were not. In terms of gender, 64 (47.1%) of all hospitalized patients were female, while 72 (52.9%) were male. There were 36 (52.9 percent) females and 32 (47.1%) males among the uncured patients. The cured patients were divided into two gender groups: 28 (41.2%) females and 40 (58.8%) males (tab. I).

The distribution of patients by place of origin and medical status at discharge revealed that of the total of 58 (42.6%) rural patients, 27 (46.6%) were uncured patients and 31 (53.4%) were cured. Furthermore, at the time of discharge, 41 (52.6%) cases of uncured patients and 37 (47.4%) cases of cured patients were reported from the urban area (tab. II). Our analysis proved that there was no link between the patient's medical status at the time of discharge and their place of origin.

Our statistical analysis showed that the average percentage of patients who were

cured at the moment of the discharge was equal to the average percentage of uncured patients at the same moment. The average percentage of male patients in the sample studied was 52.9%, whereas the average percentage of female patients was 47.1%. Also, the average percentage of patients in urban areas was 57.4%, while the average percentage of patients in rural areas was 46.2%.

TABLE I

Patient's distribution by gender and medical status

			Gender	
			Female	*Male*
Status	*Not cured*	Count % within medical status % within gender	36 52.9% 56.3%	32 47.1% 44.4%
	Cured	Count % within medical status % within gender	28 41.2% 43.8%	40 58.8% 55.6%

TABLE II

Patient's distribution by place of origin and medical status

			Place of origin	
			Rural	*Urban*
Status	*Not cured*	Count % within medical status % within place of origin	27 39.7% 46.6%	41 60.3% 52.6%
	Cured	Count % within medical status % within place of origin	31 45.6% 53.4%	37 54.4% 47.4%

The relationship and measurements between the dependent variable and each of the qualitative independent factors.

We further calculated using the confidence interval the proportion of uncured patients at the time of discharge from the patients included in the study.

The results showed that the interval [0.415; 0.584] covers the proportion of uncured patients at discharge time with a 95% confidence interval.

Regarding the specific measurements, our results proved the following data.

Measuring the association between the patient's medical status at discharge and the patient's gender:

- Probabilities: The probability of a female patient to be cured at discharge was 0.437, while for a male patient was 0.555.
- Relative risk: The risk of not being cured at discharge was 1.268 times higher for female patients compared to males.
- Odds: The odds for a female patient not to be cured at the time of discharge were 1.285, while for a male patient the odds were 0.8.

- Odds ratio for a female patient not to be cured at discharge when compared to a male patient was 1.265. In other words, female patients have 1.265 more chances of not being cured at discharge comparing to male patients.

Measuring the association between the patient's medical status at discharge and the patient's place of origin:

- Probabilities: The probability that a patient from rural area to be cured at the time of discharge was 0.534, while from an urban area was 0.474.
- Relative risk: The risk of not being cured at the time of discharge was 1.128 times higher for urban patients than for rural patients.
- Odds: The odds for an urban patient not being cured at the time of discharge were 1.109, while the odds for a rural patient were 0.873.
- Odds ratio: The odds for an urban patient not being cured at the time of discharge were 1.109, while for a rural patient were 0.873, identical as for odds.

DISCUSSION

The moment of discharge from the hospital is an essential part of the physician's role in providing comprehensive care. A rehabilitation hospital's physicians must determine whether and when a patient can be discharged in a safe and timely way while maintaining physical mobility and independence.

Matmari *et al.* (8) pointed out that the process of discharge requires an understanding of the involved individuals (patients, families, health care team), the environment (supports and resources required for successful transition to the discharge destination), the processes influencing the plan (facility and provincial policies), and how all these factors interact. In order to discharge patients in the best medical condition possible, Pashley *et al.* (9) emphasized the importance of clinical experience in shaping physician`s processes, practices, and priorities in the discharge decision making.

Studies conducted by Kirk-Sanchez (10) and Shahpar (11) examined the relationship between mobility at the time of discharge in a group of patients with orthopedic diagnoses and other associated influencing factors. The results of these studies indicated that the hours of physical therapy and occupational therapy of a patient with orthopedic diagnoses, as well as the cognitive status at admission, length of stay (LOS), and number of secondary diagnoses, can predict the mobility at the time of the discharge. The age of the patients was not found to be a predictor for the discharge medical condition. Morri *et al.* (12), on the other hand, demonstrated that age and sex are major predictive factors for patients' levels of autonomy at discharge.

In 2008, Berges *et al.* examined the effects of the patient's gender on rehabilitation outcomes following hip replacement surgery. The study highlighted the importance of gender in the medical condition of the patients at discharge, finding statistically significant differences in functional achievements among women compared to men. In this study, women began inpatient rehabilitation with lower ratings of Functional Independence Measure (FIM) than men but had greater improvements in mean FIM rating from admission to discharge (13).

Mathijssen *et al.* employed a multiple regression model to estimate the LOS as a function of a variety of independent variables to determine which factors influence

the LOS in hospitals, which directly affects the discharge outcome. Other characteristics such as age and ethnic group, in addition to the type of condition, were found to influence patient LOS (14).

According to Pashley *et al.* (9), patients may not achieve their full rehabilitative potential as a result of an early or poorly planned discharge, or they may have serious injuries that generate secondary impairments. As indicated by Henke *et al.* (15), premature discharge may result in hospital readmission. Furthermore, early hospital discharge does not always imply cost savings if patients require more intensive health care in the future. A solid quality evaluation should serve as the foundation for providing healthcare services in medical practice as well as in healthcare administration, and it could be expressed in dimensions such as: effectiveness, accessibility, professional competence, continuity, security, physical infrastructure, efficiency, interpersonal relations, comfort, choice of supplier and type of insurance or treatment (16, 17).

By evaluating the correlation between the dependent variables and each of the qualitative independent variables, the *Pearson Chi-square* analysis showed that the medical status of the patient at the time of discharge was not influenced by gender and place of origin. Our results revealed the fact that half of the sample patients were cured, and half were not; in addition, among the cured patients, there were more men than women. More specifically, the risk of not being cured at discharge was 1.268 times higher for female patients compared to males. Moreover, the estimated risk of not being cured at discharge time is 1.154 times higher for female patients from rural areas compared to males from the same place of origin.

Inadequate individual patient care could result from a physician's lack of grasp of non-clinical elements when making management decisions. Even if physicians should strive to act in a reasonable, evidence-based, and professional manner at all times, they should also consider the particular challenges of individual patients in their clinical practice and respect their values and principles. In order to provide the finest quality healthcare to all patients, treatment policies should support management of all patients equally, without discriminating between them based on gender, age, sexual orientation, religion, or race (18).

CONCLUSIONS

In our study, using econometric modeling with logistic regression, we found that the age and the length of admission in the hospital has a significant influence on the disease stabilization, even if the patients are not fully cured at discharge time. This means that with an increase in patient's age by one year, the estimated chances of a patient not being cured at discharge decrease by 3.5%. Also, with an increase in the patient's LOS in the hospital by one day, the estimated chances of a patient not being cured at discharge time increase by 8.1%. Because the research only considered data from a single regional hospital, it limits the conclusions that can be drawn from the sample. Future work should aim to extend the analysis to more hospitals, also implying a larger number of patients.

SOMATOSTATIN RECEPTORS SCINTIGRAPHY PRIORITIZATION CRITERIA BASED ON NET PATIENT EPIDEMIOLOGICAL PROFILE: A BI-CENTRIC STUDY (Abstract): This study aimed to create a generic profile of patients with NETs and to establish the prioritization criteria for somatostatin receptors scintigraphy (SRS), within the NETs diagnostic algorithm, being the first study of this kind conducted in Romania. **Material and methods:** A bi-centric, retro-prospective study comprising 103 patients with NETs, evaluated through ^{99m}Tc-TOC SRS, in two nuclear medicine departments from "Sf. Spiridon" County Clinical Emergency Hospital Iasi, Romania and Center of Nuclear Medicine, University Clinical Center of Kragujevac, Serbia. We analyzed the clinical-paraclinical features of included patients, as a starting point for streamlining the selection of patients for SRS. **Results and discussion:** The total group of patients included 47.57 % men and 52.43 % women, the age varying between 21-83 years. The most frequent primary NETs were represented by pNETs, and GI-NETs and the symptoms were nonspecific for majority of analyzed patients. Both prospective and retrospective analysis showed that SRS was followed by positive results. For prospectively analyzed patients, due to the used customized sheets, it was extremely easy to identify four SRS prioritization criteria. **Conclusions:** This study could outline the profile of patients with NETs, as the starting point for streamlining patient selection for SRS. The four prioritization criteria proposed by us could guide the diagnostic algorithm. **Keywords:** SOMATOSTATIN RECEPTORS SCINTIGRAPHY, NEURO-ENDOCRINE TUMORS.

As in the rest of the world, both in Romania and Serbia, the NETs incidence is relatively low and the nonspecific symptoms of onset are added to the diagnostic and to the therapeutic difficulties (1). Late presentation to the physician, followed by a diagnostic protocol not very well defined could contribute to the delaying a NET personalized diagnosis (2).

A minimally invasive functional imaging technique for diagnosing patients with NETs, using the prioritization criteria, could facilitate the personalized diagnostic process, with specific influences on NETs management. Nowadays, possible diagnostic errors could occur, followed by medical

ethics issues, because the imaging assessment of patients with NETs doesn't follow a very well-structured diagnostic algorithm. These observations were the basis of this study, which aimed to establish the prioritization criteria for scintigraphy of somatostatin receptors (SRS), within the diagnostic algorithm, for patients with NETs.

Our primary objective was to create a generic profile of patients with NETs, by analyzing the clinical-paraclinical features, as a starting point for streamlining the selection of patients for SRS. Secondary, the post-PRRT nephrotoxicity was analyzed. It is the first study of this kind conducted in Romania, in connection with the functional imaging of NETs.

The final results could lead to the adoption of the prioritization criteria in the current medical practice or even their implementation in the future NETs screening.

MATERIAL AND METHODS

We conducted a bi-centric, retro-prospective, study, between January 2020-May 2021, on NET patients, who performed ^{99m}Tc-SRS for diagnosis in two departments of nuclear medicine: "Sf. Spiridon" County Clinical Emergency Hospital Iasi, Romania and Center of Nuclear Medicine, University Clinical Center of Kragujevac, Serbia.

The study was included in a Ph.D. study approved by the Ethics Committee of the "Grigore T. Popa" University of Medicine and Pharmacy from Iasi.

For all patients, the same inclusion/exclusion criteria were applied (tab. I).

TABLE I
Inclusion and exclusion criteria

Inclusion criteria	Exclusion criteria
-diagnosed NETs	-the patient's refusal
-morphologically imaging evaluated within three months	-hypersensitivity to HYNIC- [D-Phe1, Tyr3-Octreotide] trifluoroacetate/another excipient
-positive biochemical NETs markers – patients > 18 years old	-hypersensitivity to sodium pertechnetate solution
-no surgery before SRS	-inflammatory digestive diseases
-no SA before/during the SRS	-pregnancy, breast-feeding

The patients were divided in two groups: group 1, prospectively analyzed (27 patients) and 2, retrospectively analyzed (80 patients). From 107 initially included patients, were finally selected 103 cases of NETs (fig. 1), four patients not being eligible due to the exclusion criteria met.

In the prospective analysis, which finally included 25 patients, we developed "*^{99m}Tc-TOC SRS personalized file*", a personalized electronic monitoring sheet, where we included personalized pts. Using these, we identified and proposed four ^{99m}Tc-TOC SRS prioritization criteria (tab. II).

Patients' preparation: discontinuation of treatment before ^{99m}Tc-TOC scan: 2-3 days for short-acting and 3-6 weeks for long-acting somatostatin analogues; in significant renal impairment, ^{99m}Tc-TOC is not recommended because the reduced /absent renal function will lead to greater radiation exposure; in hepatic impairment, no dose reduction is required; when the abdomen was the area of interest, the use of laxatives was considered in the evening before and in the evening following tracer's administration and a liquid-based diet two days before SRS (3).

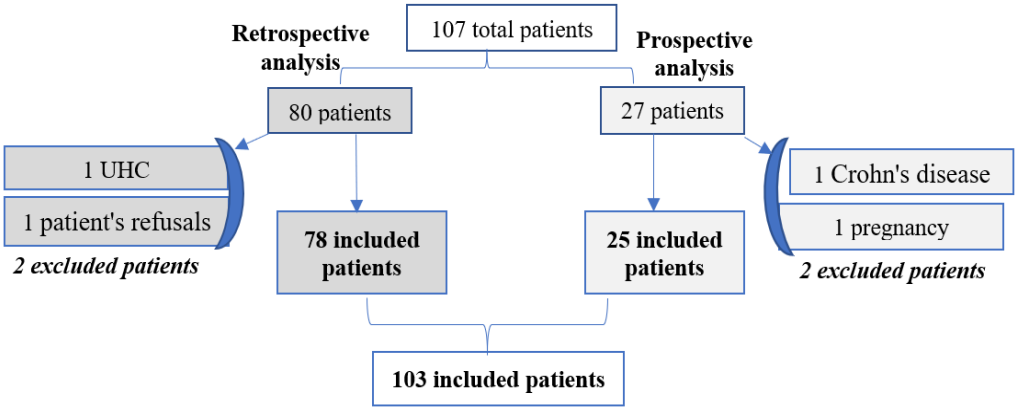

Fig. 1. The process of selecting patients with NETs
Legend: UHC (ulcerative hemorrhagic colitis); somatostatin receptor scintigraphy (SRS)

TABLE II
SRS prioritization criteria

Criteria 1	Criteria 2	Criteria 3	Criteria 4
-surgery -positive histology and minimum two positive IHC markers -negative morphologi-cal imaging (3 months post-surgery)	-without surgery -metastasis (structural imaging) -positive biochemical markers at two successive assessments -negative morphological imaging for primary NETs	-without surgery -suggestive symptomatology -metastasis (structural imaging) -negative morphological imaging for primary NETs	-suggestive symptomatology -positive biochemical markers at two succes-sive assessments; -negative morphological imaging for primary NETs

Two gamma cameras, low-energy, all-purpose, parallel hole collimator, energy window of 20%, set to 140 keV +/- 15% were used: SIEMENS E.CAM signature series, Dual-Head, Variable Angle, Cardio, 2007, Siemens, Medical Systems Inc. USA (Romania) and SIEMENS E.CAM, Dual-Head, Variable Angle, Syngo, 2006, Goldseal, Siemens, Medical Systems Inc. USA (Serbia).

Imaging protocol: In prospective analysis, the images were obtained early, at 2, 4 and 24 h and in retrospective analysis at 4 h after tracer administration: whole body (256 x 1024 matrix, 6 cm/min bed movement), planar localized (256 x 256 matrix), SPECT (128 x 128 matrix, 180° rotation detector head, 132 images, 1 image/second) images.

PRRT nephrotoxicity assessment: For patient who performed at least one single PRRT cycle, the renal function was evaluated through ^{99m}Tc-DTPA dynamic scans.

RESULTS

Prospective study

The age of the patients varying between 30-69 years, with a mean of 51. The distribution of NETs by age showed NETs' increased after 40 years old, with a maximum in the 60-69 years age group (36%). Analyzing by gender, the same increase in incidence was observed after the age of 50 in both categories, the number of female

patients exceeding the male ones in the age groups 50-59 and 60-69 years (fig. 2).

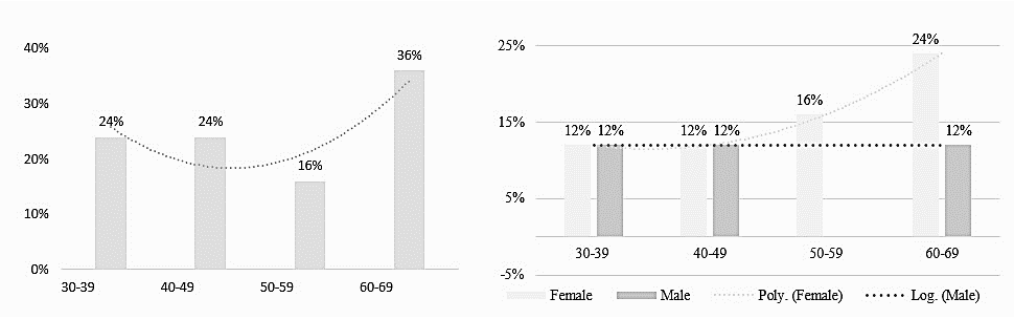

Fig. 2. Incidence of NETs by age groups. Incidence of NETs by age groups and gender

The most frequent diagnosis was GI NETs and more rare diagnosis Pheo (fig. 3).

Regarding the primary NETs sites, the pancreas was the most frequent primary site (40%), unlike adrenal gland which was less represented (4%), the thyroid and ileum primaries represented 32 % and duodenum and lung 24 %.

In all patients, the symptoms were non-specific, the most common symptoms being abdominal pain (44%), abdominal bloating (52%), transit disorders (28%), flushing (16%), weight loss (9.52%).

Although all patients were evaluated by ultrasound, at 88% of them the results were irrelevant in supporting the diagnosis of NETs. The entire group of patients was evaluated through CT imaging, but in 44% of cases were negative CT results. Five patients were evaluated by MRI, and only one patient had a pathological MRI image (right intrasellar pituitary adenoma).

48% of the patients had known or newly diagnosed associated pathology. The hypertension was observed in 58.3% of all patients and type II diabetes mellites in four cases.

Diagnosis	*No of patients*	*% of patients*
pNETs	n = 6	24%
GI NETs	n = 5	20%
Gastrinoma	n = 4	16%
MTC	n = 4	16%
Lung	n = 3	12%
Insulinoma	n = 2	8%
Pheo	n = 1	4%

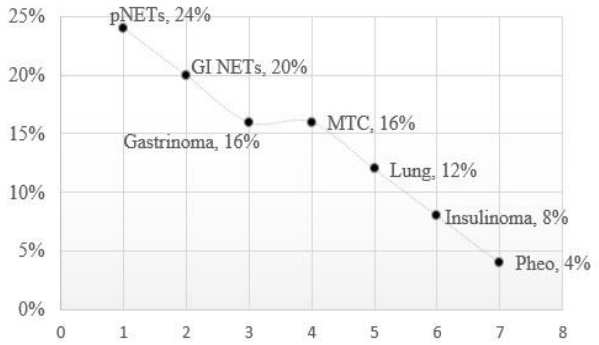

Fig. 3. Frequency of different types of NETs

SR expression

SRS had a sensitivity of 95.65% and a specificity of 50%, 22 out of 25 patients included in the study having ^{99m}Tc -TOC positive lesions.

^{99m}Tc-TOC SRS revealed a pharmaco-

kinetic profile, SR presence being evaluated due to the activity tracer concentration. Below, we present some serial images: early, at 2, 4 and 24 hrs. after injection, on which the uptake pattern can be visualized (fig. 4). The tumor uptake was seen early, at 2, and 4 hrs., at which time muscle and blood activity was markedly reduced. At 24 hrs., the pathological lesions were still visible, although the image quality is poor due to the low count rate produced by the rapid decay of ^{99m}Tc.

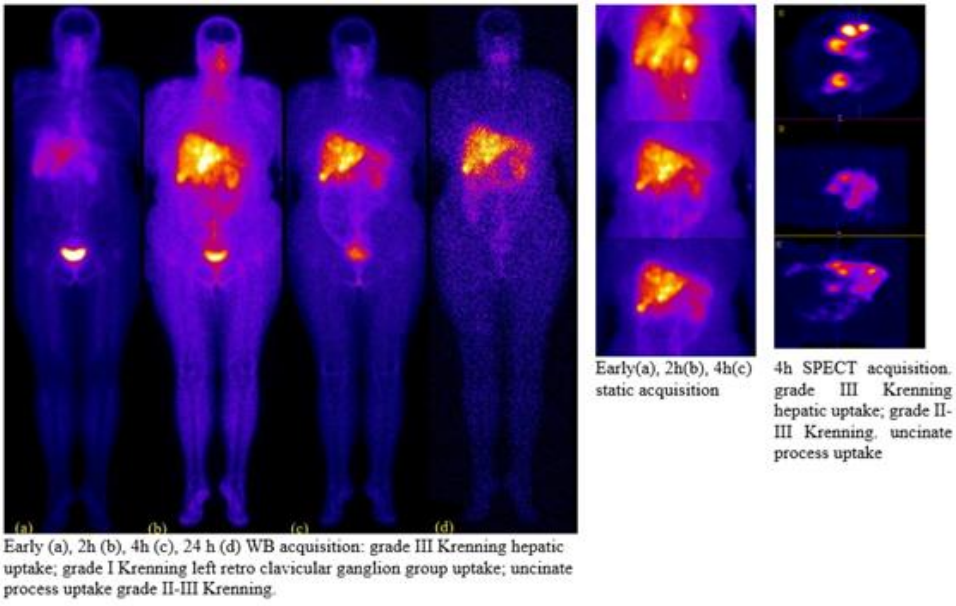

Fig. 4. Serial images: early, at 2, 4 and 24 hours after injection.

The distribution regarding the four prioritization criteria, was as follows:

- ten patients were included in Criteria 1: personalized patient files included surgery performed as the first therapeutic intention, in order to eradicate the primary NETs (five enterectomies, two pancreatectomies and three thyroidectomies), increased values of NE markers (Cg A, 5-HIIA, serotonin, calcitonin), for which morphological imaging examinations, performed at least 3 months post-surgery, could not objectify the presence of primary NETs;

- one patient with lung NET was included in Criteria 2: high values of Cg A, structural imaging showed only hepatic disseminations, without highlighting the primary pulmonary site of NET;

- nine patients met Criteria 3: personalized records of these nine patients showed the symptoms suggestive of NETs, negative structural imaging methods performed to identify the primary NET site and no history of surgery;

- the last five patients fulfilled Criteria 4: symptoms suggestive for NET but with negative neuroendocrine biochemical markers and positive structural imaging for the presence of secondary but negative

results for primary NETs.

Retrospective analysis

From 80 consecutive patients with NETs, two patients were excluded from the analysis (one patient refused the SRS and another one had ulcerative hemorrhagic colitis) and 78 patients constituted the final population. The group of patients was formed by 51.28% male, respectively 48.71% female, and the average age was 59.18 +/- 11.53 years. The most frequent diagnosis was represented by GI NETs and more rare diagnosis by Pheo (fig. 5).

Diagnosis	*No of patients*	*% patients*
GI NETs	n = 24	30.77 %
PNETs	n = 17	21.8 %
Lung	n = 14	17.9 %
MTC	n = 13	16.66 %
Rare NETs	n = 6	7.69 %
Pheo	n = 4	5.13 %

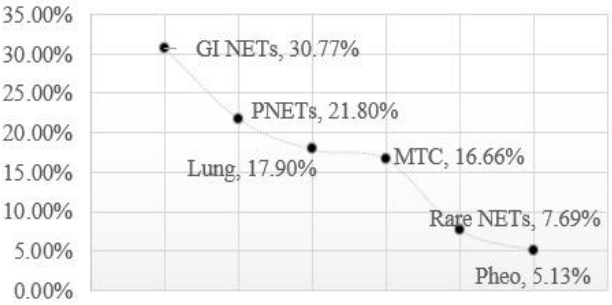

Fig. 5. Frequency of different types of NETs

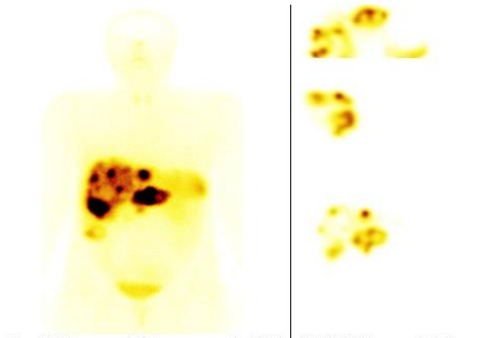
Regarding associated pathology, 12.82% of the patients had known or newly diagnosed associated pathology. Eight of ten patients had synchronous neoplasms, one patient had Hashimoto's thyroiditis and the last one had iron deficiency anemia.

SR expression



4h WB acquisition: grade IV Krenning pancreatic uptake; liver metastasis | SPECT acquisition

Fig. 6. pNETs

SRS had a sensitivity of 97.44% and a specificity of 50%. Below, we presented some images from NETs patients on which the uptake pattern is visualized (fig. 6).

PRRT ^{99m}Tc-DTPA nephogram analysis

The three patients treated with PRRT, renal function was monitored by ^{99m}Tc-DTPA nephograms.

Case 1: nephrogram showed minor changes, with discrete elongated elimination for both kidneys; a moderate tracer retention in both kidneys, on late post-micturition renal static imaging.

Case 2: nephrogram showed a slight decrease in mGFR.

Case 3: nephrogram showed a decrease in mGFR and moderate elongation of the nephrographic curves of both kidneys; moderate tracer retention in the middle calyx of the right kidney.

DISCUSSION

NETs are generally quite rare tumors,

known to have low incidence of 1-5 / 100,000 (4) and prevalence of 35 / 100,000/year (5) in the general population. However, nowadays increased studies are beginning to show an increase in the incidence of NETs.

Our NET epidemiological study realized in Romania shows that NET is still a much-underdiagnosed pathology, with an obvious incidence increase in these two centers, in accordance with the data literature. The results confirm the generic profile of the patient with NETs, presented in the literature: age over 50 years, high BMI, a general condition with comorbidities, a history of surgery and primary NETs located especially in the digestive tract, pancreas, thyroid and lung (6).

In both countries, the annual number of new cases has increased quite a lot in recent years, this increase being related also with the possibility of performing SRS. Analyzing the results, we noticed that in both centers, the highest number of NETs appears in the 57-67 age group and that the incidence of NETs in the female population in Romania was higher than in Serbia.

One of the findings of our study is that the age of the patients correlates with the incidence of NETs. The literature describes a maximum incidence after the age of 65 years old (7), fact also observed in our study.

Observing the smaller percentage of patients with NETs aged under 40 years (24%), it can be stated that the incidence of NETs in young adult patients is relatively low. However, we believe that attention should be paid to people aged under 40 years, even if, in absolute values, their representation in the total number of patients is not very high. Currently, no screening is performed for NETs and physicians tend not to consider people under 40 years in the risk category for the occurrence of NETs (taking also into account the current difficulty of guiding the diagnostic process). Furthermore, the low incidence may be caused by the low addressability of patients with NETs to the physician, due to the extremely nonspecific incipient NETs symptoms.

Due to this fact, patients with NETs could be diagnosed more than seven years after the onset of symptoms.

Nonspecific NET symptomatology is an impactful factor in the management of the patient with NETs, making the diagnostic process very difficult, for the doctor being quite difficult to orient the diagnostic process in the right direction.

The clinical status of the patient, along with the presence of possible associated comorbidities, are important elements to consider in the diagnostic process. There are studies in the literature that show that high BMI and an existing metabolic syndrome contribute to increased incidence of NETs (8). In our research, 19 patients out of 25 had BMI above the upper limit, one of the patients even suffering of morbid obesity.

In both analyzes, the first two places were ranked with the same two types of NETs, GI-NETs and pNETs, and the last place by Pheo. As an associated pathology, prospective analysis showed that some of the included patients had hypertension or diabetes mellitus; retrospective analysis showed that a fairly high percentage of patients had synchronous neoplasms.

Prospective analysis showed clearly that SRS was followed by positive results, even when the structurally imaging investigations were irrelevant from NET diagnostic point of view.

The use of customized sheets for all 25 prospective analyzed patients made extremely easy the inclusion of patients with

NETs in one of the four prioritization criteria, and implicitly to achieve, more easily, their correct management.

In the studied group of PRRT nephrotoxicity, the nephrograms showed a slight decrease in GFR, with the elongation of the elimination phases of the curves, confirming the data literature (2).

CONCLUSIONS

Starting from the analysis of the database created within the Romania-Serbia collaboration, the conclusions of this study can outline the profile of patients with NETs, as the starting point for streamlining patient selection for SRS. The four prioritization criteria proposed could guide the diagnostic algorithm, being able to contribute to the orientation of the investigating physician towards imaging investigations with decisive request, ^{99m}Tc-TOC SRS.

A standardized and well-oriented diagnostic process could positively impact the NETs diagnosis costs, reducing them only as absolutely necessary expenses, and eliminating diagnostic interventions which are consuming any kind of resources: financial, time, medical staff.

This conclusion is of particular importance for the possibility of implementing SRS prioritization criteria that could completely change the diagnostic and therapeutic personalized management for NET patients.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

SOFTWARE APPLICATION FOR ESTIMATING BIOMECHANICAL PARAMETERS OF THE HUMAN BODY (Abstract): Knowledge of the biomechanical parameters of human body segments is necessary for solving various problems in biomechanics and applications in this field. This paper presents a software tool designed for estimating biomechanical parameters of the human body, such as length of segments, center of mass, and radius of gyration, using anthropometric data of body mass and height. **Material and methods:** The software tool was designed and implemented in LabVIEW™ and was developed to determine the values of biomechanical parameters in the study of the human body, to facilitate the design of elements of orthoses, prostheses, exoskeletons, and robots. The application performs automatic calculations of biomechanical parameters of interest, based on anthropometric tables made by different investigators. **Results:** The result is a graphical interface that allows the introduction of general data of the human subject to be analyzed or an anatomical model, an interface that includes specific digital areas to display different values of anthropometric data and automatically calculated biomechanical parameters. The software was tested using different input values, and the results were compared with the data developed by classical calculation methods. **Conclusions:** Developing an experimental method that provides precise positioning of such important data as the center of gravity of the body segments and that can be widely available to scientists may allow further development in their research, without needing to use sophisticated or time-consuming equipment. The application developed by us performs automatic calculations of biomechanical parameters of interest, based on anthropometric tables made by different investigators, and can be a very useful tool for researchers. **Keywords:** MASS MOMENT OF INERTIA, RADIUS OF GYRATION, BIOMECHANICS, ORTHOSIS, DESIGN.

From a biomechanics viewpoint, human morphology can be described in terms of the following problems: biomaterials, structure, construction, geometry, and inertia (1). According to Erdmann, mass, density, the radius of the center of mass, the moment of mass (static moment), the moment of inertia, the radius of gyration, and deviation moment are inertial quantities and are known as anthropometric data (1, 2). Among the above quantities, the Mass Moment of Inertia (MOI) is of particular importance in the study of the biomechanics of the human body. Mass, Centre of Gravity (COG) and radius of gyration of each body segment are the inertial quanti-

ties required for the estimation of MOI.

An anthropometric table, useful in determining these quantities, has been generated over time, following the results of research on corpses and living subjects by several investigators: Borelli - 17th century, Weber brothers - 1836, Harless – 1860 (2), Braune and Fisher - 1889, Dempster - 1955, Clauser *et al.* – 1969, but also others (3, 4). The data compiled by Braune and Fisher were the most accurate and used by scientists.

According to Clauser (3), in 1936, Steinhausen reported a series of attempts by contemporary researchers to develop data on the weight of anatomical segments and the center of mass on living subjects. He quoted a work by Hebestreit (unpublished) that worked with a modified Borelli balance.

This device was first attributed to Borelli (1679) and later modified by du Bois-Reymond and Basler (1900 and 1931, respectively). The composition of the device consists of a rigid plate supported by an edge of the knife at one end and a sensitive dial scale at the other end (fig. 1) and was used in their studies on the total center of mass of the human body.

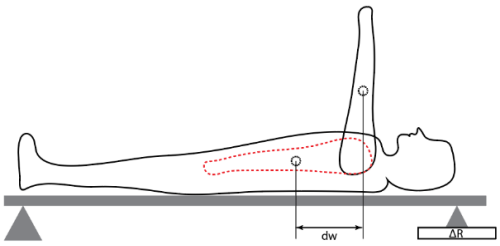

Fig. 1. Estimation of a segment's weight by the method of reaction change (Adapted from C. Clauser - 3)

The subject to be measured is positioned on the support panel of the device and knowing the weight of the subject and the distance between the supports, the center of mass of the subject can be determined by monitoring the reaction of the scales to body weight.

For example, equation 1 is used to determine the forearm weight:

$$W = \frac{D \cdot (\Delta R)}{dw} \quad (1)$$

W – Weight of forearm;

ΔR – Difference between scale readings;

D – Distance between supports;

d_w – Displacement of center of mass of forearm.

For this method to be useful for accurately determining the weight or center of mass of body segments, Bernstein concluded that the center of mass of a segment could be considered coincident with its center of the volume, since the volume and center of volume of the of a segment can be determined experimentally live. This idea was put into practice by studying frozen corpses, in order to eliminate the errors resulting from the leakage of fluids from the body (3).

In 1955, Dempster generated data on weight, volume, COG, and MOI for each segment of the human body (fig. 2). The limb segments were separated at each of the primary joints and the torso was divided into shoulder, neck, thorax and an abdominopelvic unit. The segmentation plans were similar to those established by Braune and Fischer, except that before dismemberment, the joints were flexed, which Dempster believed would provide an equitable distribution of tissue mass in each segment. After flexion, the joints were frozen before being bisected. After sectioning, each segment went through a series of five steps:

1. the segment was weighed;
2. the center of mass of the straight-

ened part was established on a balanced plate;

3. the oscillation period was determined (for the subsequent determination of the moment of inertia);

4. the volume was measured by the Archimedes method;

5. the parts were then re-frozen and prepared for further segmentation.

The segmental centers of mass were located using a balanced plate specially designed for Dempster's study (3).

In 1957, Bartner used data obtained by Braune & Fischer, Fischer and Dempster to estimate the weights of body segments from a subject's body weight (4).

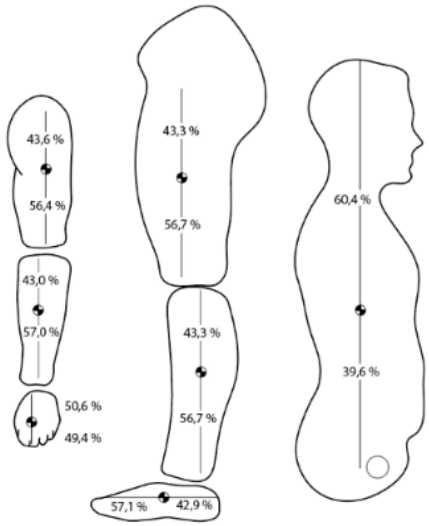

Fig. 2. Location of mass centers of body segments (Adapted from W. Dempster - 7)

The studies of Santchi *et al.* demonstrated that in a three-dimensional body such as the human body, several axes can pass through the COG, so the results lead to several MOIs (approximately three orthogonal axes defined as the intersection of three anatomical planes of the body, ie sagittal, frontal and transversal) (2). In a uniform field of gravity, the center of mass (COM) is the same as the center of gravity (COG) (5).

Knowing the biomechanical parameters of a subject's body segments (e.g., mass, volume, center of mass, mass moment of inertia) facilitates an analysis of motor activity and thus emphasizes how it can perform high-performance motor functions safely. It is important to find an experimental method that provides a precise positioning of such important data as the center of gravity of the body segments, widely available to scientists and that allows further development in their research, without the need of sophisticated or time-consuming equipment.

A good knowledge of the parameters of the body segment helps to facilitate optimal design of elements of orthoses, prostheses, exoskeletons, and robots.

This paper presents a software tool that we designed for estimating biomechanical parameters of the human body, such as length of segments, center of mass, and radius of gyration, using anthropometric data of body mass and height.

MATERIAL AND METHODS

The software application for the automatic calculation of biomechanical parameters of interest was made based on anthropometric tables made by different investigators. For example, Table I contains segment weights (head and neck, torso, upper arm, lower arm, hand, thigh, calf, foot) as a percentage of body weight reported by different investigators (Harless, Braune and Fisher, Fisher, Dempsters, Clauser *et al.*, Hall) (2). Table II contains segment lengths as a percentage of body height as compiled by Hall, and segment COG expressed as a percentage of segment length is provided in Table III (2, 6).

TABLE I

Segment weights as percentage of body weight (2, 6)

	Anatomic segment							
Investigators	**Head & neck**	**Torso**	**Upper arm**	**Lower arm**	**Hand**	**Thigh**	**Calf**	**Foot**
Harless	7.6	44.2	3.2	1.7	0.9	11.9	4.6	2.0
Braune &Fischer	7.0	46.1	3.3	2.1	0.8	10.7	4.8	1.7
Fischer	8.8	45.2	2.8	-	-	11.0	4.5	2.1
Dempster	8.1	49.7	2.8	1.6	0.6	9.9	4.6	1.4
Clauser *et al.*	7.3	50.7	2.6	1.6	0.7	10.3	4.3	1.5
Hall	8.2	46.84	3.25	1.8	0.65	10.5	4.75	1.43

TABLE II

Segment length as percentage of body weight (2)

Segment	Length in percentage
Head & neck	10.75
Torso	30.00
Upper arm	17.20
Lower arm	15.70
Hand	5.75
Thight	23.20
Calf	24.70
Foot	14.84

TABLE III

Distance of segment centre of gravity from proximal end as percentage of segment length (2)

Segment	COG distance in percentage
Head & neck	56.7
Torso	56.2
Upper arm	43.6
Lower arm	43.0
Hand	46.8
Thight	43.3
Calf	43.4
Foot	50.0

These data were implemented in LabVIEW™ (Laboratory Virtual Instrumentation Engineering Workbench), a platform and a development environment for the visual programming language from National Instruments (8).

Thus, the program generates a series of estimated results regarding the values of the moment of inertia, of the radius of gyration and of the positioning of the center of gravity of each segment. These results are calculated based on the general information of the human body (mass and height) which is entered by the user of the software.

A Graphical User Interface (GUI) is an interface between the user and electronic devices such as computers, portable devices, electronic devices, and some medical or non-medical equipment. To present all available information and actions, a graphical interface provides icons and visual indicators, as opposed to text-based user interfaces, which provide command names to be entered or scanned in the text (9, 10). It is intended to facilitate the user's work by eliminating the process of writing software code or entering repetitive data, and thus reducing the risk of errors by the user of the tool, which can sometimes lead to erroneous results. Due to the advantages of graphical interfaces, this concept was also used in this paper.

RESULTS AND DISCUSSION

The resulting graphical interface consists of a control panel and input of general data about a subject or anatomical model, a panel for displaying different values of anthropometric data and a panel displaying the calculated biomechanical parameters, as follows:

a) **Subject parameter control panel** is the area where the user of the application enters the general data that refers to the mass (kg) and height (m) of the subject (fig. 3);

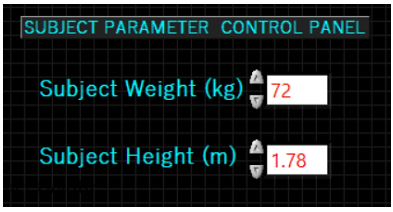

Fig. 3. Subject parameter control panel

b) **Anthropometric data display panel** displays the values of mass (kg) and length (m) of the segments of the human body with reference to the points a, b, c, d, e, f, g, h (fig. 4). This area of the application is for viewing only, not for control.

c) **Biomechanical parameters display panel** allows the visualization of the values of the biomechanical parameters calculated with the anthropometric data obtained in panel b). Similar to the previous one, panel c) displays the results for Radius of Gyration – *k* (m), Mass Moment of Inertia – *I* (kg·m^2), Centre of Gravity Location – *COG* (m). The first two sets of values are calculated for three planes of the human body, namely sagittal, frontal and transverse (fig. 5).

d) The complete interface of the application also contains a graphical representation of the human body with references for each body segment for easy orientation, as follows: a – head and neck; b – torso; c – upper arm; d – lower arm; e – hand; f – thigh; g – calf; h – foot (fig. 6).

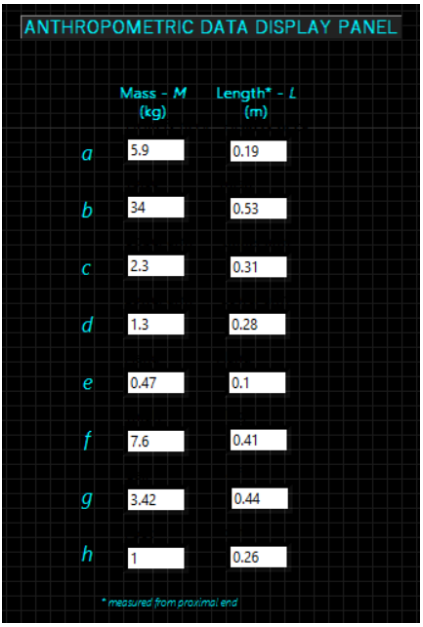

Fig. 5. Anthropometric data display panel

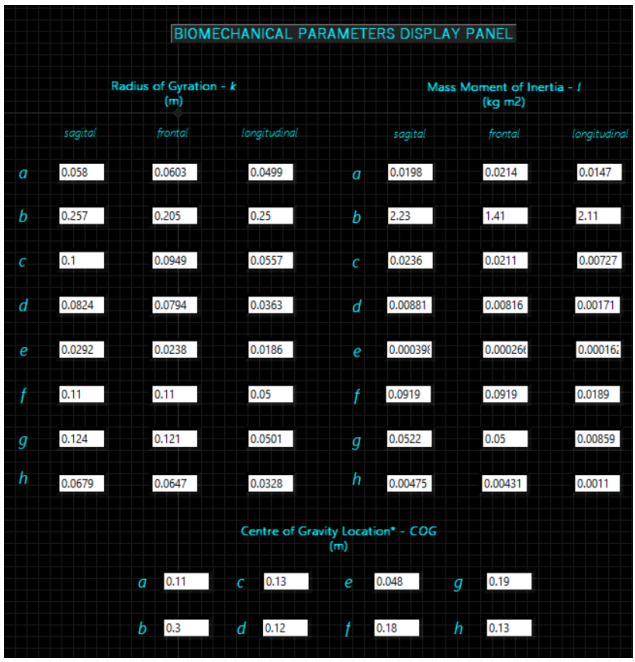

Fig. 6. Biomechanical parameters display panel (includes values for Radius of Gyration – *k* (m), Mass Moment of Inertia – *I* (kg·m^2), Centre of Gravity Location – *COG* (m))

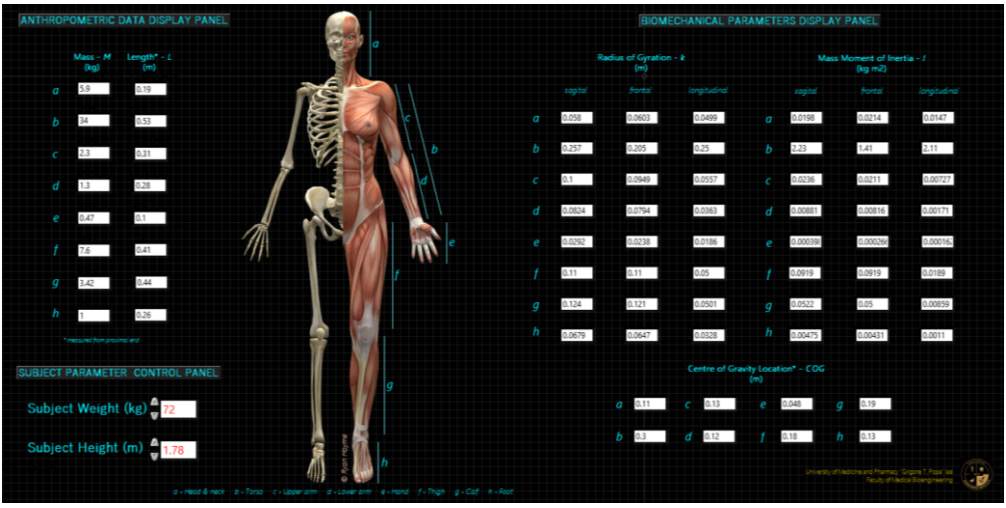

Fig. 7. Graphical user interface of the application

For parameters relating to the length of the human body segment and the location of the center of gravity, the measurement shall be made from the proximal end of the corresponding segment.

To validate the values calculated through the developed application, a group of 18 subjects was analyzed. The subjects were

weighed, and their height was measured. In this verification we were interested in the values of the length of three segments (thigh length - f, calf length - g and leg length - h).

These values are necessary for the design and development of knee braces. Table IV shows the 18 subjects examined, the values measured directly on the patient and the values calculated using the software program developed.

TABLE IV

Comparison between the values of the measured segment lengths and the determined ones (MV-measured values, DV-determined values)

CONCLUSIONS

Experience in recent years has shown that the proper development of orthoses, prostheses, rehabilitation devices, and medical instruments requires a thorough understanding of the biomechanical principles of human body performance.

The design of rehabilitation devices such as active orthoses can be optimized for better customization and human-machine compatibility.

The application developed by us performs automatic calculations of biomechanical parameters of interest, based on anthropometric tables made by different investigators, and can be a very useful tool for researchers.

Knowing the biomechanical parameters of a subject's body segments (e.g., mass, volume, center of mass, mass moment of inertia) facilitates an analysis of motor activity and thus emphasizes how it can perform high-performance motor functions safely. It is important to find an experimental method that provides precise positioning of such important data as the center of gravity of the body segments, widely available to scientists which may allow further development in their research, without needing to use sophisticated or time-consuming equipment.

Given the growing interest in "controller/agent" medical systems, it is necessary to have a good knowledge of the parameters of the body segment to design the necessary medical equipment. The data can allow the design of more comfortable equipment and chairs, for example for the high comfort of the surgical specialist who is in charge of the "source" module of a medical device. Also, control systems, such as the pedals of a piece of equipment, can be customized according to the situation and the anthropometric data of the user. In many situations, it is necessary to simulate the human body, so it is necessary to manufacture a test dummy with real anatomical dimensions for self-crash studies on seat belts, for first aid maneuvers, robots for exploring dangerous spaces, or others.

In this application, there must be complete data of body parameters. The uses of body segment parameter data are indeed quite numerous. The complete evaluation of these quantities by using a software application can be an important contribution in the field of biomechanics.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and this research was funded by the University of Medicine and Pharmacy "Grigore T. Popa" from Iaşi, based on contract no. 19565/01.10.2020.

NEWS

EARLY IDENTIFICATION OF CAROTID VULNERABLE PLAQUE IN ASYMPTOMATIC PATIENTS

Atherosclerosis (AS) is the root cause of cardiovascular and cerebrovascular diseases, including coronary artery disease and stroke. Atherosclerosis is an independent risk factor for cardiovascular and cerebrovascular diseases. Plaque rupture and subsequent thrombosis are the main causes of myocardial infarction and stroke. With the continuous improvement of people's living standards, the occurrence of cardiovascular and cerebrovascular events is showing a younger trend, and some senile diseases such as hypertension, cerebral infarction, and myocardial infarction appear earlier, increasing the mortality and disability rate of people. Therefore, early detection and effective intervention of patients with atherosclerotic cardiovascular and cerebrovascular disease (ASCCVD) is an important measure to reduce cardiovascular and cerebrovascular disease and its complications. AS is a systemic, long-term, slowly progressing inflammatory disease. The basic lesions are lipid deposition in the intima of the artery, focal fibrosis of the intima, and atheromatous plaque formation. Atherosclerotic plaques are divided into stable plaques and unstable plaques, unstable plaques are also called vulnerable plaques. The methods of identifying vulnerable plaques early include: multi-slice spiral CT, nuclear magnetic resonance, radionuclide imaging, optical coherence tomography, etc. There are few studies on early identification and intervention of carotid vulnerable plaques in patients with asymptomatic health checkups and there is no standardized diagnosis and treatment recommendations at present. The purpose of this study is to explore the influencing factors of atherosclerotic plaque formation and stability in patients with asymptomatic carotid atherosclerotic plaques. Also, the authors proposed to identify the vulnerable plaques and find the patients of asymptomatic ASCCVD earlier through combining the non-invasive carotid artery ultrasound and the detection of serum plaque stability markers so as to conduct the clinical intervention, delay the progress of plaque, avoid thrombosis and prevent the occurrence and development of ischemic cardiovascular and cerebrovascular diseases (Jiao Y, Qin Y, Zhang Z, *et al.* Early identification of carotid vulnerable plaque in asymptomatic patients. *BMC Cardiovascular Disorders* 2020; 20: 429).

DESIGN AND OPTIMIZATION METHOD FOR OBTAINING PIOGLITAZONE AND CURCUMIN-LOADED CHITOSAN NANOPARTICLES

DESIGN AND OPTIMIZATION METHOD FOR OBTAINING PIOGLITAZONE AND CURCUMIN-LOADED CHITOSAN NANOPARTICLES (Abstract): **Aim**: The aim of the present study was to design and optimize the method used for preparation of CS NPs loaded with pioglitazone (P) and curcumin (C), as a new multi-target polymeric nanosystems, for type 2 diabetes mellitus therapy. **Material and methods**: CS NPs loaded with pioglitazone, curcumin and pioglitazone-curcumin were prepared using ionic gelation method. After setting the optimal parameters, the developed nanosystems (CS_P NPs, CS_C NP and CS_P_C NPs) were characterized in terms of morphological aspects, using Scanning Electronic Microscopy (SEM) and of average particle size and poly dispersity index, using Dynamic Light Scattering (DLS) measurements. In addition, the zeta potential values, an important parameter for physical stability of the NPs, was also studied. **Results and discussion**: The following parameters were set as optimal, which assure the obtaining of NPs with proper characteristics: CS 0.1% (wt/v):TPP 0.1% ratio of 3:1, tween 80 0.05% (wt/v), DMSO as solvent, sonication during 30 min, rotational speed of 1,400 rpm. **Conclusions**: The developed CS_P_C NPs are stable nanosystems with proper physical characteristics (PS = 215 nm, PI = 0.300, ZP = 11.13 mV), which support to continue our studies, using *in vitro* and *in vivo* assays, to prove their efficiency as multi-target polymeric nanosystems. **Keywords**: CHITOSAN, NANOPARTICLES, PIOGLITAZONE, CURCUMIN.

Diabetes mellitus (DM) is one of the most serious chronic diseases, which is considered an important public health problem and a social-economic one due to the increased prevalence from last decades (1). Worldwide, diabetes causes nearly 4 million deaths annually, while another 1.5 million new cases are diagnosed and it is estimated that in 2040 one in ten people will suffer from this disease (2).

The most common form of diabetes is type 2 diabetes mellitus (T2DM), representing 85% of diagnosed cases. Its prevalence having increased in recent decades because of the careless lifestyle of the people. Also, it is worrying that the incidence among children and youngers is increasing (3).

The chronic hyperglycemia is the major cause for serious complications in various organs or tissues. The complications can be acute (diabetic ketoacidosis, hypoglycemia) or chronic, microvascular (diabetic retinopathy, neuropathy and nephropathy, diabetic foot) and macrovascular (cardiovascular diseases) (4).

The treatment of T2DM, which is depends on the stage of disease, include different classes of drugs: sulfonylureas, biguanides, inhibitors of alpha-glucosidase, glinides, thiazolidinediones and modulators of incretins (agonists of GLP-1 receptors and inhibitors of DPP IV enzyme). Thiazolidinediones (pioglitazone, rosiglitazone and lobeglitazone) is a relatively new class of oral antidiabetic agents which acts as selective agonists on peroxisome proliferator-activated receptors-gamma (PPAR-gamma), thus improving the endogenous insulin sensivity in the liver, muscles and adipose tissue (5). Pioglitazone significantly decreases the glycosylated hemoglobin (HbA1c), reduces fasting and postprandial blood glucose levels, as well as improves pancreatic beta-cell function. Unfortunately, this drug has a low oral absorption, a low water solubility and a short half-life (3-6 h), which limit its efficiency.

It is known that the hyperglycemia generates reactive oxygen species (ROS) which can produce the destruction of the cellular structure. Moreover, it was proved that the oxidative stress acts as a mediator of the insulin resistance and glucose intolerance, being involved in the development of diabetes mellitus and its micro and macrovascular complications (6). In this context curcumin, a natural polyphenolic compound, has been shown to have significant antioxidant activity and a potential hypoglycemic effect in experimental diabetic animal models (7). Unfortunately, it presents some disadvantages including hydrophobicity, poor solubility in water, low absorption and faster metabolism in the gastrointestinal tract which contribute to its poor bioavailability (8).

In the last time the researchers focused their studies on nanotechnology field, as a new strategy for enhancing the solubility, improving the biological performance and decreasing the toxicity of the drugs. Some intensely studied nanosystems are nanoparticles (NPs) which are used as drug delivery systems due to small particle size (between 1-100 nm) and large surface area. These nanosystems present numerous advantages such as high stability, feasibility of incorporation of different drugs, even hydrophobic ones, and high carrier capacity. There nanosystems are able to reduce the doses frequency, to provide sustained and controlled release of encapsulated substances, to increase the stability, bioavailability and absorption of the drugs (9). In addition, they can be used for targeting drugs to cells and tissue through the capacity to penetrate into cells by endocytosis or receptor-mediated transcytosis (10, 11).

The chitosan (CS), frequently used to

develop NPs, is a natural polysaccharide which is considered the largest biomaterial, after cellulose, used in various medical and pharmaceutical applications (12). It attracted the interest of the researchers firstly due to its unique properties: biocompatibility, biodegradability and low toxicity and secondly due to its important biological effects in diabetes and its complications therapy including antioxidant, antimicrobial, hypocholesterolemiant and antitumoral effects (13, 14).

This paper aims to describe the optimization of the method used for preparation of CS NPs loaded with pioglitazone and curcumin, as a new multi-target polymeric nanosystem, able to increase the bioavailability of the loaded drugs and so improve the pharmacological effects, targeting T2DM.

MATERIAL AND METHODS

Materials: chitosan low molecular weight (CS LMW, molecular weight 50-190 kDa, 75-85% deacetylation degree, viscosity 20-300 cP), pentasodium tripolyphosphate (TPP), acetic acid (min. 99.8%, p.a. ACS reagent), tween 80, curcumin, pioglitazone, were purchased from Sigma Aldrich. All other reagents were analytical grade and were used as received without further purification.

Preparation of pioglitazone/curcumin/ pioglitazone-curcumin-loaded CS NPs

The drugs (pioglitazone - P, curcumin - C, pioglitazone-curcumin) were loaded into CS NPs using ionic gelation method (15). Briefly, CS LMW 0.1% (wt/v), was dispersed in acetic acid solution 0.15% (v/v) and the mixture was stirring for 2 h at room temperature to obtain a clear polymeric solution. To 3 mL of CS solution, pioglitazone (2 mg/3.5 mg), curcumin (5 mg/6 mg) or pioglitazone-curcumin (2 mg/5 mg, 3,5 mg/6 mg) dissolved in 0.5 mL of methanol or DMSO was added. Then 1 mL of TPP aqueous solution 0.1% (wt/v) was added drop wise with a micropipette under stirring. The formation of colloidal solution indicates the reticulation of NPs.

În order to optimize the reticulation method for obtaining stable pioglitazone-loaded CS NPs (CS_P NPs) and curcumin-loaded CS NP (CS_C NPs), different parameters were changed, CS 0.1% (wt/v):TPP 0.1% (wt/v) ratio (3:1, 3:1.5); presence or absence of surfactant, tween 80 0.5% (wt/v); presence or absence of sonication; type of solvent (methanol, DMSO) and the rotational speed (1,000 rpm, 1,400 rpm). The optimized parameters were applied further to obtain the pioglitazone-curcumin-loaded CS NPs (CS_P_C NPs).

Characterization of pioglitazone/curcumin/pioglitazone-curcumin-loaded CS NPs

The scanning electron microscopy method (SEM), using a Desktop SEM (Phenom, The Nederland), was applied to study the morphological aspects of the NPs. The average particles size (PS) of the colloidal NPs was determined using Dynamic Light Scattering (DLS) and the poly dispersity index (PI) was evaluated via light scattering measurements. The zeta potential (ZP) of the NPs was determined using a Easier Nano ZS90 instrument (Malvern Instruments, Malvern, UK) by placing NPs, after dispersing in distilled

water at 25°C, in disposable zeta cells. The electrophoretic mobility between the electrodes was converted to a zeta potential, depending on the Smoluchowski diffusion equation. All measurements were performed in triplicate.

RESULTS AND DISCUSSION

The influence of the concentration of the drug (pioglitazone, curcumin), CS 0.1% (wt/v): TPP 0.1% (wt/v) ratio, of type of solvent, of using or not of sonication, of presence or absence of tween 80 0.05% (wt/v), as surfactant and of the rotational speed, on formation of CS_P NPs and CS-C NPs respectively, in terms of particle size (PS) and poly dispersity index (PI) is presented in tables I and II.

					1400	3197/3278	0.471

In both cases, CS_P NPs and CS_C NPs, the optimal parameters were set as follow: CS 0.1% (wt/v):TPP 0.1% ratio of 3:1, tween 80 0.05% (wt/v), DMSO as solvent, sonication during 30 min, rotational speed of 1400 rpm. Using these parameters, the smaller NPs were obtained: 217 nm (CS_$P_{2\ mg}$ NPs), 257 nm (CS_$P_{3.5mg}$ NPs) and 234 nm (CS_C_{5mg} NPs) and 277 nm (CS_C_{6mg} NP), respectively (fig. 1). For CS_P_C NPs the recorded PS were 215 nm (CS_P_{2mg}_C_{5mg} NPs) and 382 nm (CS_$P_{3.5mg}$_C_{6mg} NPs), respectively. For all these NPs the smallest PI was recorded (fig. 1).

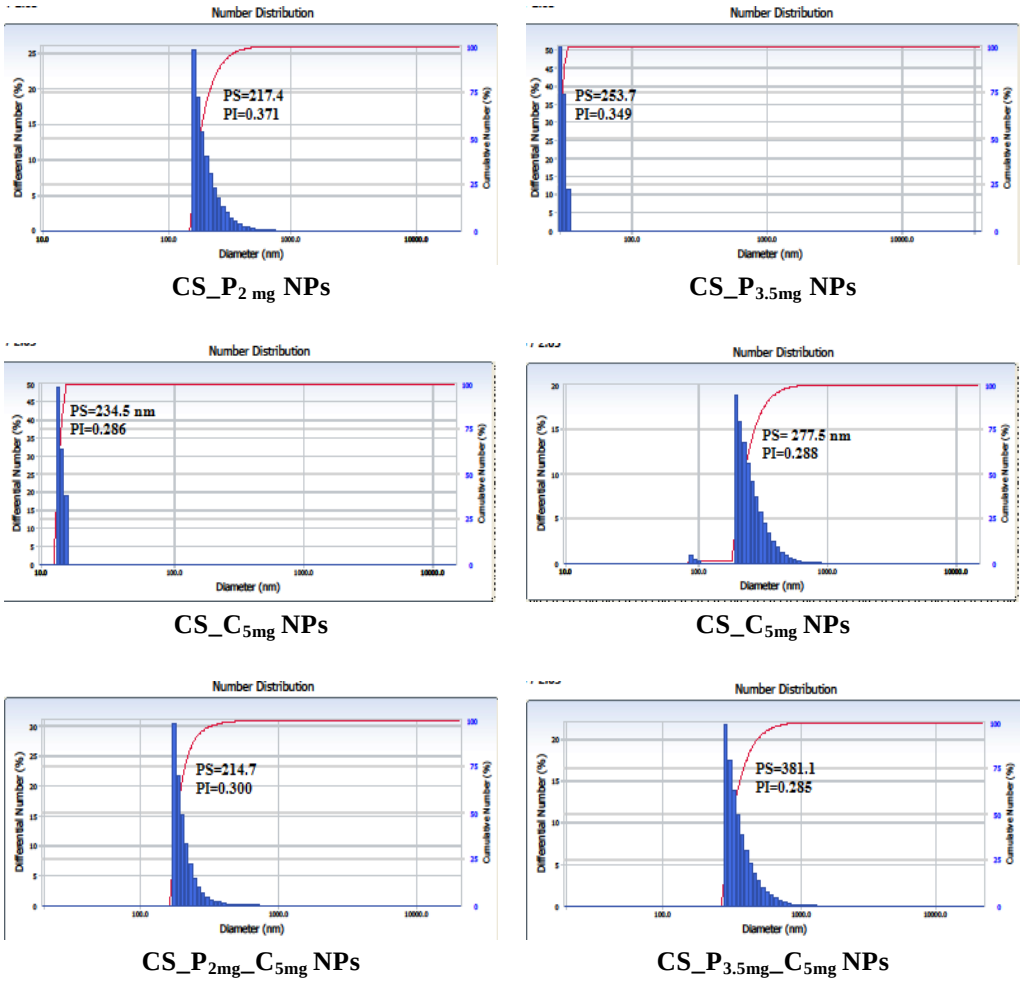

Fig. 1. Particle size (PS) distribution and poly dispersity index (PI) of optimized CS_P NPs, CS_C NPs, CS_P_C NPs at different concentrations.

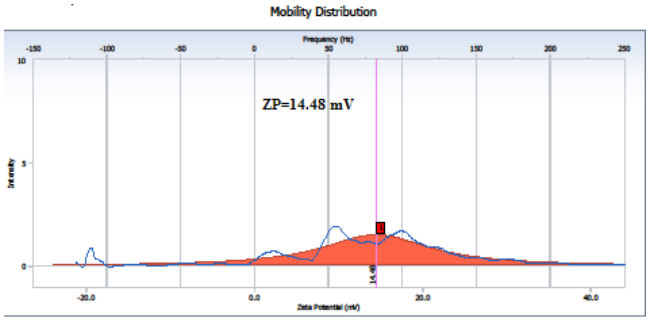
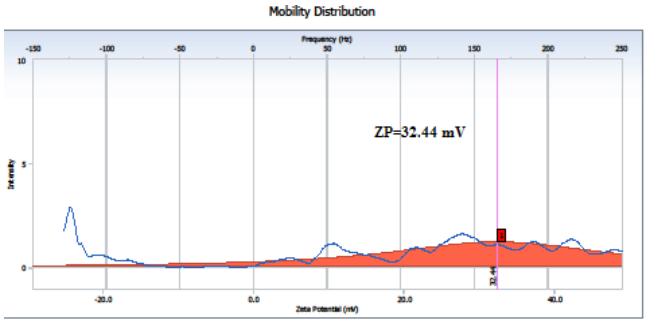
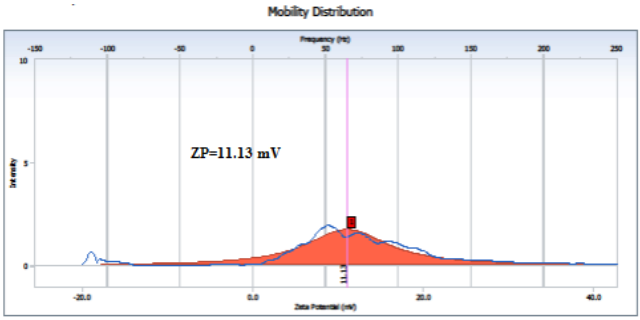


CS_P$_{2mg}$ NPs



CS_C$_{5mg}$ NPs



CS_P$_{2mg}$_C$_{5mg}$ NPs

Fig. 2. Zeta potential (ZP) values for CS_P$_{2mg}$ NPs, CS_C$_{5mg}$ NPs and CS_P$_{2mg}$_C$_{5mg}$ NPs.

The physical stability of the developed NPs (CS_P NPs, CS_C NPs and CS_P_C NPs) was evaluated in term of ZP, a parameter closely related to the charge of the particles. It is well documented that the aggregation of the NPs is depending on following factors: the small particle size, the large surface contact and the free energy (15). The ZP value shows the repulsion degree between the electrically charged and dispersed NPs. A high ZP value means a certain charge value of the NPs which gives them a sufficient repulsive force to prevent the particle aggregation. If the ZP has a low value, the attrac-

tion force of the particles exceeds of that of repulsion and as result the particles adhere to each other to form agglomerates (8). The optimal value of ZP, which assure the stability of the NPs, what means a low risk for aggregation and increasing of the PS is between 20-40mV (11). As is observed from fig. 2 the ZP of the developed NPs was lower than 40 mV, that means they have increased stability. The ZP values recorded for these NPs was as follow: 14.48 mV (CS_P_{2mg} NPs), 32.44 mV (CS_C_{5mg} NPs) and 11.13 mV (CS_P_{2mg}_C_{5mg} NPs).

In addition, the SEM images (fig. 3) proved the formation of the NPs using the optimized parameters.

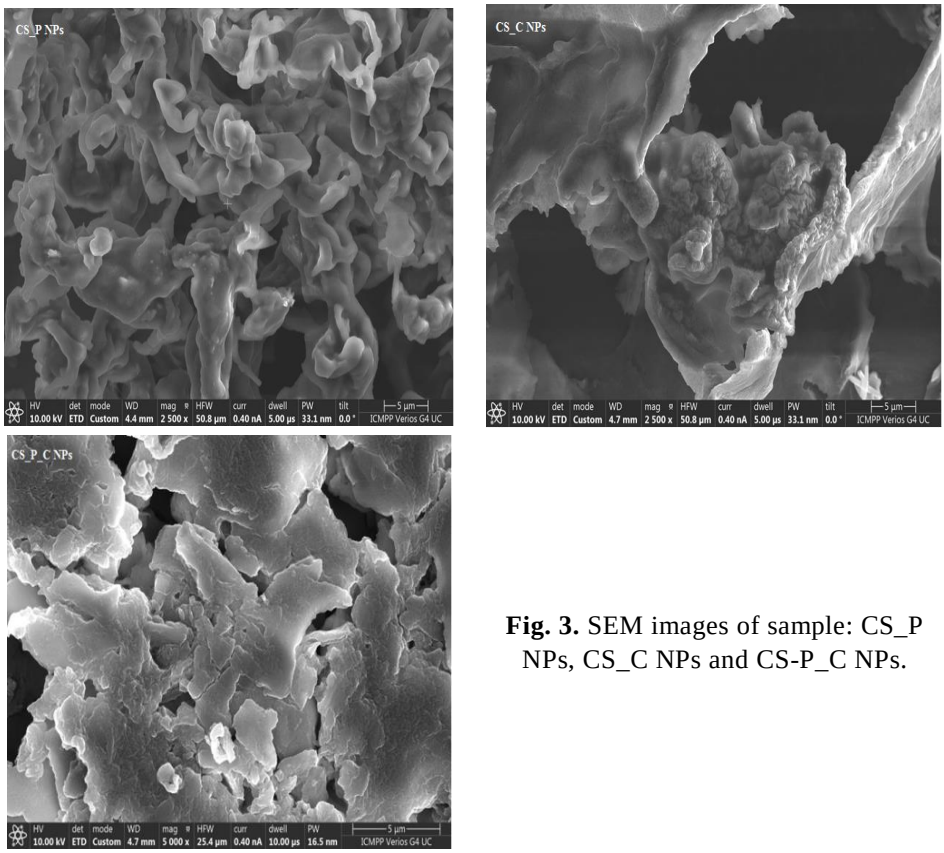


Fig. 3. SEM images of sample: CS_P NPs, CS_C NPs and CS-P_C NPs.

CONCLUSIONS

New CS NPs loaded with pioglitazone (CS_P NPs) and curcumin (CS_C NPs) were designed and their obtaining process was optimized, considering the size of the NPs and the poly dispersity index as key elements to successful preparation. The ionic gelation method, used for preparation, was optimized by changing different parameters such as: concentration of the drugs, polymer: reticulation agent ratio (CS:TPP), presence/absence of surfactant, presence/absence of sonication, type of solvent and rotational speed. Based on optimization process of CS_P NPs and CS_C NPs respectively, new CS NPs loaded with pioglitazone

and curcumin (CS_P_C NPs) were prepared and characterized. The results support the successful preparation of the CS_P_C NPs based on small particle size, proper poly dispersity index and low zeta potential, which assure the physical stability of the developed nanosystems. These nanosystems will be further tested, using *in vitro* and *in vivo* assays as new potential candidates for management of T2DM.

CONTEMPORARY ASPECTS OF PROVISIONAL FIXED PROSTHESIS (Abstract): Provisional prosthetics in the rehabilitation algorithm with fixed restorations has a number of particularly important roles in transmitting the data absolutely necessary to the dental laboratory for the achievement of the definitive work, which influences the healing of periodontal tissues and, definitively, the occlusal scheme and the resizing of the vertical occlusal dimension. The **aim** of this study is to analyze the factors involved in the choice of provisional prosthesis and the implications this has for the definitive prosthesis according to the particularities of each individual case. **Material and methods:** A total of 86 patients diagnosed with partially reduced edentulousness, i.e., coronal recessed dental lesions, were included in the study group and clinically and paraclinically evaluated for prosthetic rehabilitation by different types of definitive restorations from the current prosthodontic range, prefaced within the therapeutic algorithm of provisional restorations. **Results:** The current clinical-technological algorithm of rehabilitation with fixed restorations, provisional prosthetics represents an extremely important step in order to conform the periodontal tissue on the one hand, to protect the prepared substructures on the other hand, and last but not least to prefigure the shape of the future prosthetic rehabilitation in the context of dento-somatic-facial harmony. **Conclusions:** Prosthetic restorations made by the digital technique are extremely precise, their design is laborious considering all biomechanical aesthetic criteria so that we have individualized restorations that lead to successful final prosthetics. **Keywords:** TEMPORARY FIXED PROSTHESES, PMMA, DIGITAL APPROACH, AESTHETICS, GENERAL STATUS.

Over time, fixed prosthetics has gone through important evolutionary stages in terms of the biomaterials used and the technological line approached, with particular attention being paid to the therapeutic algorithm used in contemporary society. Thus, we cannot talk about fixed prosthesis without being preceded by provisional protection, this stage being particularly important both from a morphological and functional point of view (1).

Provisional prosthetics in the rehabilitation algorithm with fixed restorations has a number of particularly important roles in transmitting the data absolutely necessary to the dental laboratory for the achievement of the definitive work, which influences the healing of periodontal tissues and, defini-

tively, the occlusal scheme and the resizing of the vertical occlusal dimension. It is important to mention that the provisional prosthesis configures the correct morphology for the performance of the phonatory function at optimal parameters as well as for the design of the aesthetic aspects related to the shape and its integration into the dento-somato-facial harmony (2, 3).

Successful clinical outcome is dependent on a whole range of factors in which the effectiveness of the provisional protection is essential and is also a relevant starting point for the patient expectations related to prosthetic work in provisional prosthetic restorations may be of shorter duration or long-lasting, being recommended in different clinical situations where laborious therapeutic interventions are performed in the periodontal territory (4, 5, 6).

For a long time considered as an accessory, the provisional prosthesis has become, during the evolution of theoretical and practical knowledge and therapeutic resources, one of the "key" stages of fixed prosthetic restorations. A quality transitional prosthesis is a prosthesis that fulfils its roles: aesthetically, functionally, therapeutically.

The aesthetic role of the transitional restoration is the most spectacular result of the transitional prosthesis, the restoration has the advantage that it can be retouched in such a way that the laboratory receives a model that accurately reproduces the shape, volume, placement of convexities, accompanied by explanatory notes on color, shade, make-up (7, 8, 9).

The functional role of the provisional prosthesis includes three aspects: dental, periodontal, functional. Dental appearance refers to the morphological resolution of the edentulousness and the recovery of the primary function affected by the edentulousness: aesthetic for the frontal area or masticatory for the lateral area. With preparation, the biomechanical value of the teeth decreases, whether vital or not, mechanical protection against chemical or microbial aggression must be ensured. The provisional prosthesis acts as a barrier between the prepared tooth and the oral environment. A tight denture-prosthetic seal, even if it is provisional, is a conditioning factor for isolation from the oral environment. Although imperfect, thermal insulation allows the vitality of the teeth to be maintained, thereby also contributing to patient comfort. Occlusal aspect, using provisional prostheses restores static and dynamic occlusal contacts, the point of contact with antagonists and neighbors. Dental migrations after preparation, impression and occlusal or proximal retouching of the definitive prosthesis are limited. The provisional prosthesis allows quality control of the preparation and volume of the definitive restoration, avoiding occlusal interferences. The periodontal aspect aims to maintain the marginal gingiva in a physiological position after the preparation of dental substructures (10, 11, 12).

AIM

The aim of this study is to analyze the factors involved in the choice of provisional prosthesis and the implications this has for the definitive prosthesis according to the particularities of each individual clinical case.

MATERIAL AND METHODS

A total of 86 patients diagnosed with partially reduced edentulousness, i.e., coronal recessed dental lesions, were included in the study group and clinically and para-

clinically evaluated for prosthetic rehabilitation by different types of definitive restorations from the current prosthodontic range, prefaced within the therapeutic algorithm of provisional restorations.

RESULTS

In prosthetic therapy by conjunctive means, the provisional prosthesis is an indispensable element in both single and large restorations. Without excluding the protective role of the prepared substructures, the subtle occlusal, periodontal, and functional requirements of temporary restoration remain an indisputable fact. The "dialogue" provisional prosthesis - practitioner - patient has as its motto but, and as a conclusion at the same time, a definitive piece correctly integrated into the functionality of the dental system.

Regarding the distribution of the group of patients according to sex, a percentage of 56% for women and 44% for men was recorded, the sex of the patient correlated with age, general status and aesthetic demands directs us towards a certain type of prosthetics to be grafted according to the individuality of each clinical case with the demands of contemporary aesthetics (fig. 1).

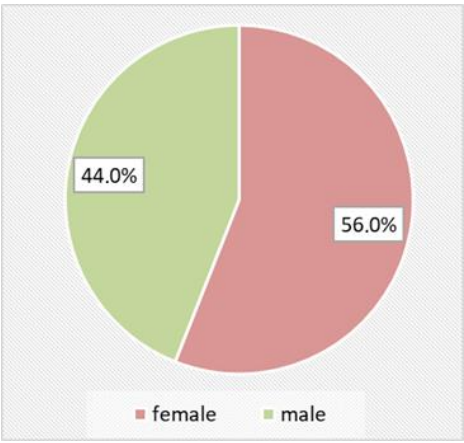

Fig. 1. Distribution of patients according to gender

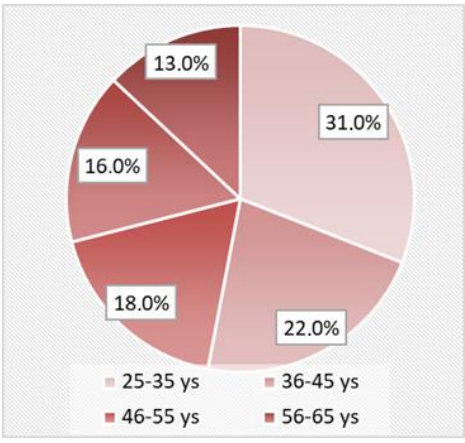

Fig. 2. Distribution of patients according to age

Regarding the age of the patients we have a wide range from 25 to 75 years as prevalence of coronary dental lesions and partially reduced edentulousness, this pathology is found in a percentage of 31% in the age range 25 - 35 years, a percentage of 22% is found in the age range 35 - 45 years, while for the age range 45 and 55 years a percentage of 18% is found, for the age range 55 - 65 years a percentage of 16% is found and a percentage of 13% is found in the age range 65 - 75 years (fig. 2).

The general condition of the patient has always been an extremely important starting point for dental therapy, as many general diseases influence the structure of the oral cavity and the medication for each pathology, thus decisively influencing the therapeutic algorithm and the choice of the type of preparation and the type of prosthesis. Thus, cardiovascular diseases were recorded in the highest percentage in the group analyzed in

a percentage of 32%, it is important to note that of this percentage a quarter were taking anticoagulant medication, as for metabolic diseases, they are found in a fairly high percentage of 28% within the general pathology followed by respiratory diseases in a percentage of 15% and digestive diseases in a percentage of 13%. A percentage of 12% was recorded in patients with general oncological diseases which are often associated with long-term temporary prostheses such as PMMA (fig. 3).

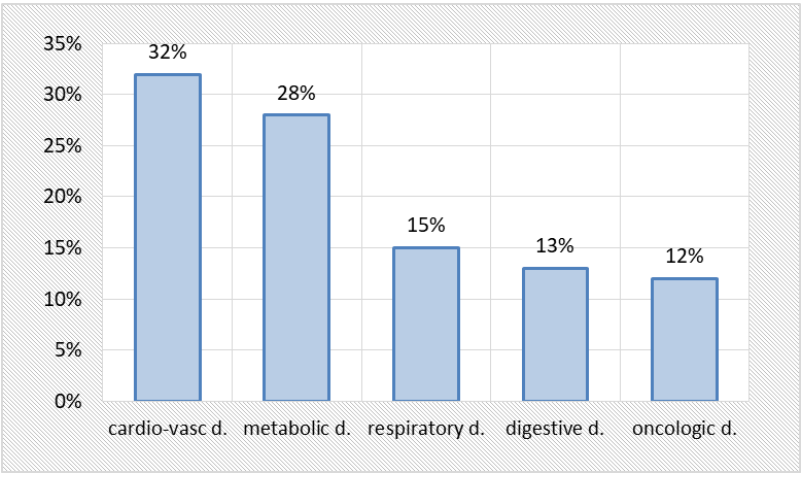

Fig. 3. Distribution of patients according to the assessment of the general condition

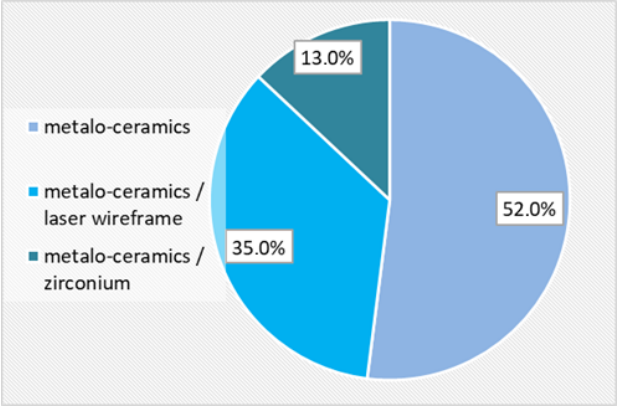

Fig. 4. Distribution of the types of performed fixed prostheses

As far as definitive restorations are concerned, classical metal-ceramic restorations prevailed as a percentage, followed by metal-ceramic restorations with laser frameworks, a current technology which is extremely precise and which provides the best periodontal reports, with a percentage of 13% of zirconium-ceramic restorations made with digital techniques. As for the type of provisional prosthesis, it was anchored both in the digital and in the classical territory (fig. 4).

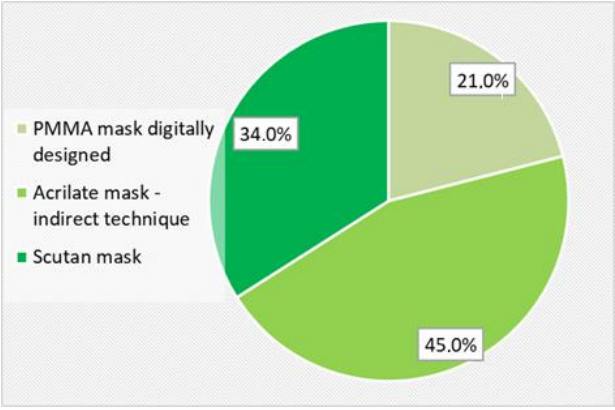

Fig. 5. Distribution of temporary prostheses performed

The design of provisional prostheses by means of digital technologies was carried out in a 21% percentage of patients, followed by classical acrylic prostheses which were found in a percentage of 45% and Scutan mask carried out in the dental surgery was found in a percentage of 34% (fig. 5). As regards the location of temporary restorations, 64% of the restorations were placed at the frontal level, of which 30% were temporary restorations that were preceded by gingivectomy-type prosthetic preparations; 36% were placed at the lateral level .The accuracy of adaptation of the transitional denture margins to the preparation limits is the key factor in periodontal protection. It allows, by its anatomy, dento-periodontal hygiene, so it must respect the "shapes" of a definitive restoration. At the cervical level, its morphology must fit in with the morphology of the neighboring teeth, respecting the natural convexities, which on the one hand divert the food bolus away from the marginal gingiva and at the same time allow, through the play of muscles, self-cleaning. For Parkinson, "the gingival super contour protects the dental plaque, not the gingiva". Over contours appear to be much more harmful than under contours (for definitive restorations), especially if the restorative boundary is placed subgingival. The dimensions of the periodontal biological space are maintained by correctly shaped provisional denture margins, the volume of the margins compatible with a correct emergence profile and the surface condition of the material perfectly polished, thus avoiding inflammatory reactions. Provisional prosthetics by the digital method was extremely important in cases that had prosthetic work with which the patient was not very satisfied, by means of this prosthesis, exploring all the possibilities of functional morphological reconfiguration and occlusion ratios, so that the patient's expectations were assured. A concrete case in this regard was the realization of a PMMA prosthesis that was applied after a gingivectomy, the patient having been previously restored with a zirconia-supported ceramic work, the future restoration being also zirconia-supported ceramic. The frontal curvature will be completely restored, and the shape of the teeth modified according to the patient's facies so that

the final results will be as expected (fig. 6).

Another clinical situation was represented by a digital restoration, also applied in the frontal area, an area of maximum exigency. This time the method was represented by a long-term provisional prosthesis until the patient's general status could be balanced so that the absolutely necessary prosthetic preparation steps could be carried out in this clinical case (fig. 7).

Fig. 6. Digital and clinical aspects of PMMA provisional rehabilitation

Fig. 7. Aspects of long-term provisional prosthesis

DISCUSSION

It is also necessary for the patient-practitioner-technician trio: for the patient it compensates for aesthetic and/or functional disability, for the practitioner because it has therapeutic value, authorizing him to continue treatment, and for the technician because it is a source of clinical data that allows him to comply with the highest demands of the patient and the practitioner. The lifetime of this prosthesis is limited in time and the degree of development depends on the goals and duration of treatment. The provisional prosthesis is of so much interest in joint therapy that its absence may be surprising. The biological integration of the fixed prosthesis, i.e., the congruence of the prosthetic part (non-biological in terms of the method, design, and materials from which it is made) with the supporting biological elements, is conditional on achieving bio functional stability (occlusal, periodontal, aesthetic).

CONCLUSIONS

In the current clinical-technological algorithm of rehabilitation with fixed restorations, provisional prosthetics represent an

extremely important step in order to conform the periodontal tissue on the one hand, to protect the prepared substructures on the other hand, and last but not least to prefigure the shape of the future prosthetic rehabilitation in the context of dento-somatic-facial harmony. Prosthetic restorations made by the digital technique are extremely precise, their design is laborious considering all biomechanical aesthetic criteria so that we have individualized restorations that lead to successful prosthetics.

The clinical reality gives the transitional prosthesis essential functions of control and management of occlusal, periodontal, and aesthetic-functional parameters.

DEVELOPMENT AND EVALUATION OF INDOMETHACIN LIPOSOMAL SYSTEMS (Abstract): **Aim:** Treating the inflammation with oral indomethacin might be in some situations inadequate for patients that cannot dispense the medication on their own, a fact that conduct to the necessity to develop new pharmaceutical formulations administered through different pathways, such as the transdermal application. To trespass the skin layers, this study aimed to develop and evaluate an indomethacin liposome formulation that will be included in a Carbopol gel, subsequently. **Material and methods:** To develop indomethacin liposomes egg lecithin and cholesterol were used in order to confer membrane stability and elasticity. Two technologies of liposome-sizing were used: extrusion and sonication, the obtained vesicles being incorporated in a Carbopol gel. The *in vitro* release profiles were conducted on both liposomes and gels using the Franz cell method and two types of membranes (M1 and M2). **Results:** Liposome sizing through extrusion proved to be a better method compared to the sonication one. The microscopic evaluation of the liposomal vesicles showed that through extrusion smaller liposomes are obtained, a fact that is reflected also in their capacity for API releasing. **Conclusions:** Via the *in vitro* releasing study differences of 10% were observed regarding the amounts of API liberated, through both the extruded liposomal dispersion and the gel containing this dispersion in comparison with the sonicated liposomes. The type of releasing membrane used influenced the amount of API released, observing a higher concentration of API released after 8 hours through M2 (the skin-like membrane). **Keywords:** INDOMETHACIN, LIPOSOMES, TRANSDERMAL, FRANZ CELL.

Non-steroidal anti-inflammatory drugs (NSAIDs) are the most prescribed classes of drugs in the world for treating rheumatoid polyarthritis and osteoarthritis. Indomethacin (Ind) is a well-known NSAID used as a long-term treatment in these kinds of pathologies, thus, its main disadvantage during oral administration is represented by the gastric side effects such as ulcer, digestive hemorrhage, allergy, and respiratory and hematology disorders. Ind is an indole derived compound, with the IUPAC name 2-{1-[(4-Chlorophenyl)carbonyl]-5-methoxy-2-methyl-1H-indol-3-

yl}acetic acid having the following physico-chemical properties: white-yellowish powder, photosensitive, with the molecular mass of 357.8 g/mol, insoluble in water, partly insoluble in alcohol. 90% of the NSAIDs users are patients over 65 years old, the fact that implies a risk regarding the side-effects increase (1-3).

To decrease the risk and to improve the bioavailability of the medicines, the pharmaceutical industry started developing new pharmaceutical formulations such as liposomes. Besides the minimization of the well-known side-effects belonging to an NSAID, the transdermal administration of formulations in which the API is processed as liposome can facilitate skin penetration, improving bioavailability. A major advantage of the liposomes is given by their capacity to encapsulate different types of API and biocompatibility (4-8). The API liposomal systems have the advantage of incorporating this API, therefore, protecting it from degradation and transformation into inactive metabolites, also, the API is vectorized to the unhealthy cells, providing a gradual release. In this manner, the toxicity caused by a conventional administration decrease, and the distribution to other organs is hindered or reduced. The liposomes do not represent a pharmaceutical formulation lacking disadvantages, the loss or fusion of the APIs entrapped, or the oxidation of the phospholipids in the composition being some of them. Liposomes, named also, microparticle lipidic vesicles, bi-layered lipidic membranes, are constituted of lipids, their lipophilic parts being oriented through the internal and external part of the membrane, forming a mixture of lipidic substances, more often being used the phospholipids (phosphatidylcholine, phosphatidylserine), octadecyl amine and cholesterol (9-14). Taking into consideration the exposed introduction, this study aimed to develop and evaluate Ind liposomes that will be furthermore processed in a Carbopol gel for transdermal administration.

MATERIAL AND METHODS

***Materials for liposome preparation*:** indomethacin (Sigma Aldrich Milan, Italy), egg lecithin (AppliChem GmbH, Germany), cholesterol (Fagron, Greece), ethanol (Chimreactiv, Romania), phosphate saline buffer pH 7.4.

In first table is presented the composition of the Ind liposomal dispersion.

TABLE I.
Liposomal composition

Ingredient (g)		Function
Indomethacin	0.2	active pharmaceutical ingredient
Egg lecithin	0.2	stability and elasticity of the liposomal membrane
Cholesterol	0.018	stability and elasticity of the liposomal membrane
Ethanol	25	solvent
Phosphate saline buffer	25	adjusting pH

Liposomes preparation method: In the first step the lecithin, cholesterol, and Ind are dissolved in ethanol under continuous stirring for 20 minutes at 300 rpm (Heidolph RYR1 stirrer, Germany, fig. 1). During the second step, the dispersion is added gradually, using an Eppendorf pipette, drop by drop, in 25 g of phosphate saline buffer pH 7.4. A liposomal dispersion of 0.4% Ind is obtained.

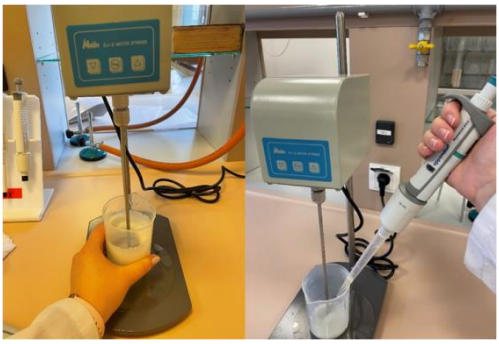

Fig. 1. Liposomes preparation method

Decreasing the liposomes vesicle size:

Extrusion: The liposomal dispersion was sized by the 8-time passage through two syringes of 250 µL belonging to the Mini Extruder (fig. 2, left), provided with a supported filter at one of the ends. The passage from one syringe to another was realized through a support membrane located between the two syringes. The extruded liposomal dispersion will be furthermore coded as Lex.

Sonication: The liposomal dispersion was subjected to the ultrasound action, in an iced water bath (fig. 2, right) (t=2.5-4°C) for 20 minutes, in innings of 5 minutes with pauses between them of 5 minutes. The extruded liposomal dispersion will be further coded as Lsn.

Fig. 2. Liposomes sizing equipment

Liposomes aspect: The liposome aspect was evaluated microscopically, using a digital binocular microscope with a camera (Optika Microscopes, Italy), the objective of the camera of 100 X.

***Materials for Carbopol gel preparation*:** carbopol 940 (BF Goodrich), sodium hydroxide solution 10% (Merck, Germany), distilled water.

In Table II is presented the composition of the Carbopol gel.

TABLE II.

Carbopol gel composition

Ingredient (g)	
Carbopol 940	1
Sol. NaOH 10%	3
Distilled water	96

Carbopol gel preparation method: The carbopol gel was prepared using the classic method of polymer hydration and neutralization with NaOH 10% to increase the viscosity and the pH.

Carbopol gels with indomethacin liposomes preparation method: 2 formulations of Ind gels were prepared, the first one consisting of liposomes obtained through extrusion (Gex), whilst the second one was prepared with sonicated liposomes (Gsn).

The quantity of liposomal dispersion incorporated ensures an amount of API of 40 µg/g gel.

Rheological evaluation of Carbopol gel

To determine the rheological behavior

of the gels a rheometer Rheotest RV was used (Rheotest RV, Germany), supplied with coaxial cylinders S/S1 and 12 shear rates.

In vitro release study:

Samples (1 g): Lex; Lsn; Gex; Gsn.

Apparatus: series of Franz cells (PermeGear, Germany), 11.28 mm clear jacketed with flat ground joint, 8 ml receptor volume, pinch clamp, and stir bar.

Acceptor phase: phosphate buffer pH 7.4, maintained at 37°C±1°C.

From the acceptor compartment of the Franz cell, samples of 0.8 mL were withdrawn at different time intervals for a period of 8 hours. The acceptor phase was immediately replaced with fresh phosphate buffer maintained at 37°C±1°C.

Tested membranes: two types of membranes were used to evaluate the release profiles of the drug from the analyzed samples:

-M1: Teknokroma membrane filters, nylon, 0.45 µm thickness, 25 mm diameter; requires hydration before use

-M2: Strat-M Membrane, 0.45 µm thickness, 25 mm diameter; has two polysulphonated layers (corresponding to epidermis and dermis) similar to the human skin layers, and polyolefin layers that simulate the porous aspect of the skin.

The cumulative amounts from the tested formulations were quantified by a validated HPLC method at 237 nm: injected volume: 10 µL, flow rate: 1 mL/min., mobile phase: formic acid solution 0.1% (25 %) + methanol (75 %), retention time: 2.9 min, stationary phase: Nucleodur C18 Gravity 3 µm column.

RESULTS AND DISCUSSION

Liposomes aspects

The microscopic evaluation of the liposomes obtained through extrusion (fig. 3) showed that through this method smaller vesicles are obtained in comparison with the ones sized through the sonication method (fig. 4). This aspect can suggest a better dermal penetrability of the extruded liposomes.

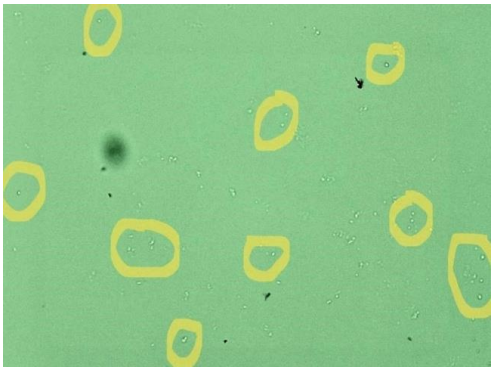

Fig. 3. Extruded liposomes aspect

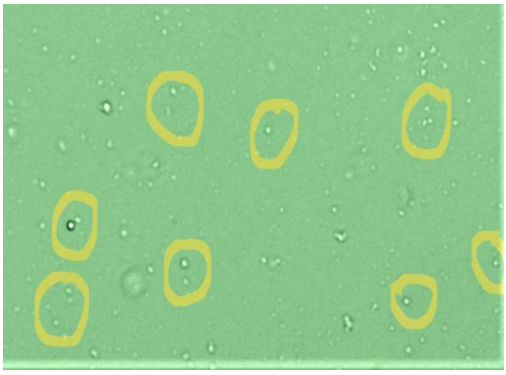

Fig. 4. Sonicated liposomes aspect

Rheological evaluation of Carbopol gel

The rheological analysis of the Carbopol gel shows a plastic behavior (fig. 5) characterized by a modification of the structure only after the tangential tension reaches a certain limit (flow threshold). Over this threshold and during the shear rate is increasing the viscosity starts to decrease.

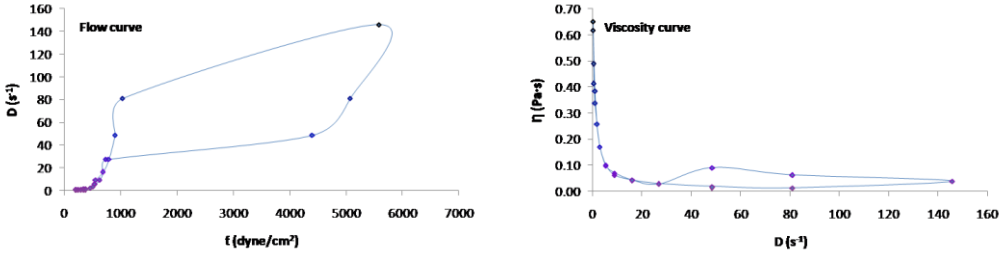

Fig. 5. Rheological behavior of the Carbopol gel

In vitro release study

The etalon scale and typical chromatograms are included in figure 6.

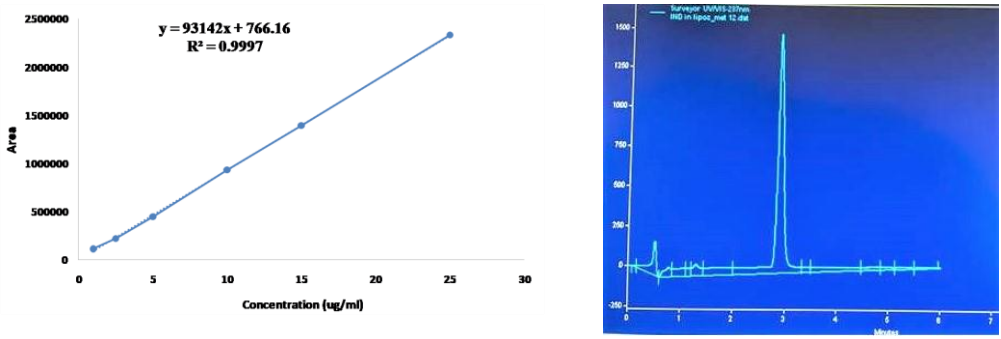

Fig. 6. Standard curve of indomethacin and a typical chromatogram

Through the API *in vitro* releasing study from the liposomal dispersions, it has been noticed after 8 hours that the extruded vesicles are easily trespassing the tested membranes in comparison with the ones obtained through sonication. Also, the type of membrane tested in the study differentiates the amount of Ind released. It can be observed that in the case of the extruded liposomes with the M2 membrane (skin-like membrane), 13% more of the API is released in comparison to the M1 membrane. Similar behavior is retrieved in the case of the sonicated liposomes, the difference in the amount of API released being 10 % (fig. 7).

Ind passaging through the membrane from the carbopol gels that included liposomes maintained the same behavior manifested also at the releasing study from the liposomal dispersion, with the distinction that after 8 hours the concentration of API released was in general, lower. This behavior might be explained by the initial necessity to release API from the gels followed by the passage of the testing membrane. Also, in the case of the liposomal gels, it was observed the importance of the membrane tested during the *in vitro* releasing study, noticing that the gels with extruded liposomes and the ones with extruded liposomes, that via the M2 membrane a higher amount of Ind is released (10% higher) compared to M1 (fig. 8).

These results suggest that in physiological conditions Ind might passage the skin layers to ensure a systemic anti-inflammatory effect.

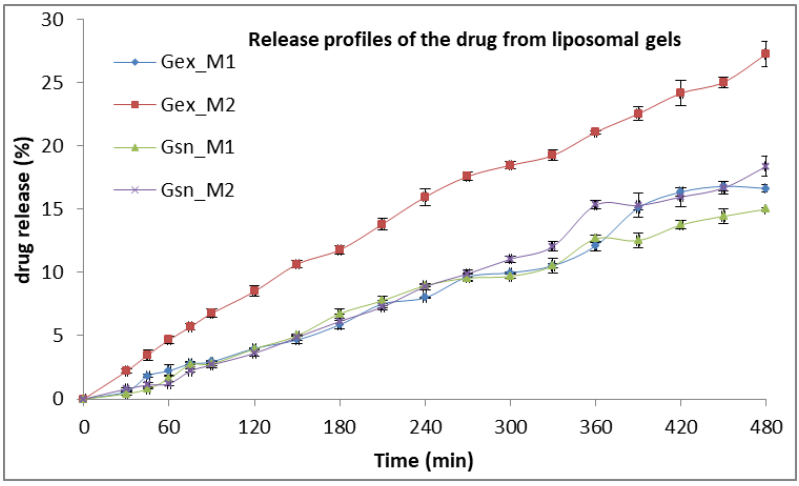

Fig. 8. Release profiles of indomethacin from liposomal gels across M1 and M2

CONCLUSIONS

The oral anti-inflammatory treatment can be in some situations inadequate for some patients that can administer by themselves the medication. In this manner and to minimize the Ind side-effects, the formulation of transdermal gels with medicinal liposomes can be an adequate solution for the pathologies treatment that includes an inflammatory process.

The liposome-sizing through extrusion proved to be a better method compared to the sonication one. The microscopic evaluation of the liposomal vesicles showed that through extrusion smaller liposomes are obtained compared to the ones obtained through sonication, a fact that is reflected also in their capacity for API release.

Through the *in vitro* releasing the study, differences of 10% of API released were observed for both extruded liposomes and gel with extruded liposomes compared to the sonicated liposomes. The releasing membrane type also influenced the amount of API released, observing a higher concentration of API released after 8 hours through M2 (the skin-like membrane).

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and this work was supported by the "George Emil Palade" University of Medicine, Pharmacy, Science and Technology of Targu Mures, Research Grant No. 10127/15/17.12.2020.

ANTIOXIDANT AND ENZYME INHIBITORY EFFECTS OF *MORUS SP*. EXTRACTS (Abstract): *Morus* leaves water extracts are used for a long time for its anti-diabetic, anti-inflammatory, and cardiovascular disease-treating properties. Our research's **objective** was to evaluate the hypoglycemic and antioxidant effects of *Morus* leaves extracts obtained by using different solvents. **Materials and methods**: The extracts from *Morus nigra* and *Morus alba* leaves were obtained by ethanol-water extraction, respectively hot water extraction. We assess the enzyme inhibition (α-amylase and α-glucosidase) ability of extracts from *Morus sp*. leaves, and we correlate these effects with polyphenols and flavonoids content. **Results**: Total polyphenols content ranged between 89.4 mg gallic acid equivalents/g ethanol-water extract of *Morus nigra* leaves and 46.81 mg gallic acid equivalents/g aqueous extract of *Morus alba* leaves. Ethanol-water extracts contain more polyphenols and flavonoids than aqueous extracts. The most important effect on alpha-amylase was presented by the ethanol-water extract from *Morus alba* leaves (EC50 88.26±0.52 µg/mL) and on alpha-glucosidase by the ethanol-water extract from *Morus nigra* leaves (EC50 69.86±0.03 µg/mL mL). From the point of view of antioxidant effects, the extracts inhibit lipoxygenase, with the maximum effect in the case of the ethanol-water extract from *Morus alba* leaves (EC50 23.75±1.77 µg/mL). The ethanol-water extracts have a greater capacity to chelate the ferrous ion compared with aqueous extracts, the most active being the ethanol-water extract from the *Morus nigra* (EC50 213.32±0.26 µg/mL). **Conclusion**: The conducted study highlights the ability of the analyzed extracts to control the enzymes involved in the digestion of carbohydrates and to reduce oxidative stress. **Keywords:** *MORUS ALBA*, *MORUS NIGRA*, ANTIOXIDANT ACTIVITY, ANTIDIABETICS.

Diabetes mellitus is the most common endocrine disease affecting over 537 million adults worldwide in 2021 with a predicted rise to 643 million by the end of the decade (1). Type II (T2DM) is the major form of diabetes, accounting for about 90% of the cases. Diabetes is caused by impaired insulin secretion, insulin resistance or a combination between the two which leads to a dysregulated metabolism of the

carbohydrates and lipids (2). Chronic hyperglycemia induces oxidative stress, affects many biological structures, and represents the most important cause for diabetes consequences such as peripheral neuropathy, diabetic retinopathy, diabetic nephropathy, or diabetic ketoacidosis.

The management of diabetes involves, among lifestyle changes, administration of oral hypoglycemic substances which are associated with side effects such as hypoglycemia, weight gain (insulin, sulphonyl urea), lactic acidosis (biguanide), and gastrointestinal disturbances. Therefore, herbal medicines present an attractive alternative in the management of diabetes as they are generally accepted to present less adverse effects compared to modern conventional pharmaceutics (2). Moreover, considering that more than three quarters of adults living with diabetes are in low- and mid-income countries both the patients and the national healthcare institutions could benefit for herbal alternative medicines as they are generally less expensive than synthetic pharmaceutics (1, 2). In the recent years, the number of studies on using plants as a source of diverse biologically active substances with anti-inflammatory, diabetic, cardiovascular diseases, anti-cancer, and antioxidant effects have increased (3, 4). The bioactive substances from plants, such as: polyphenols, phenolic acids, flavonoids, flavonols, diterpenes, tannins, phytosterols, fatty acid esters, phenylpropanoids, alkaloids, glycosides, etc., have attracted significant interest in medicinal chemistry and natural product research (5, 6).

Polyphenols are divided into four main classes: flavonoids, phenolic alcohols, stiblins, lignans and represent the biologically active substances found in plan-based diets. The structure and proprieties of these compounds depend on several factors, such as plant cultivar/genotype, growing environment conditions, soil characteristics, harvest time, and storage conditions. These substances come from plants, such as fruits, vegetables, cereals, and coffee, and are an integral part of the human diet. Polyphenols are also recognized as a preventative for degenerative illnesses (7).

Polyphenols and flavonoids, by their hydroxyl groups can scavenge free radicals, release hydrogen that will neutralize different oxidants and also, they have the ability to interact with different enzymes and to control activity of these (7). Depending on the source and combination, they may exhibit diverse properties such as specific enzyme inhibition activity.

α-Amylase and α-glucosidase are two important enzymes responsible for catabolizing starch, glycogen and disaccharides to glucose that will be absorbed into the blood. Inhibition of these enzymes is often employed for controlling blood glucose level by decreasing the rate of intestinal carbohydrate metabolism.

Oxidative stress participates in the onset and worsening of diabetes. The identification of compounds that have both antioxidant effects and the ability to control the enzymes involved in the digestion of carbohydrates represents an advantage for the patient with diabetes because the number of drugs administered to him is reduced.

Morus alba, *Morus nigra* and *Morus rubra* are woody plant from the Moraceae family that has been cultivated worldwide in sericulture from ancient times. They have been used in Chinese medicine for several purposes such as antifever, diuretics, protection of the liver, improvement of eyesight, and to prevent cardiovascular diseases. *Morus sp*. main active compo-

nents and the compositions of phenol, alkaloid, and flavonoid, have been thoroughly investigated for their noteworthy characteristics (8). Mulberry fruits are used as a natural treatment to reduce the blood pressure, to treat fever or to prevent liver and kidney damage (9, 10, 11). The antithrombotic, anti-obesity, antiinflammatory, anti-carcinogenic and neuroprotective effects of mulberry fruit flavonoids are registered in the Pharmacopoeia of the People's Republic of China (12).

Morus sp. leaves polyphenols are functional compounds possessing various beneficial effects against cardio metabolic diseases, including anti-hyperglycemic, antihyperlipidemic, anti-obesity, antihypertensive, anti-oxidative, anti-inflammatory, anti-atherosclerotic, and cardioprotective effects (4). Leaves of *M. nigra* are commonly used by women during menopause as a replacement for the conventional hormonal substitute therapy, with a similar effect to the estrogens (13). Roots, bark, stem twigs, and fruits of *Morus sp.* possess valuable bioactive ingredients that can be explored in pharmaceutical, health care, cosmetic and food industries (8).

The aim of our study was the assessment of antioxidant and enzyme inhibition (α-amylase and α-glucosidase) ability of extracts from *Morus sp*. leaves and to correlate these effects with polyphenols and flavonoids content.

MATERIAL AND METHODS

Chemicals and reagents

Reagents: Folin-Ciocalteu's Reagent, gallic acid, sodium nitrite, aluminum chloride, acarbose, alpha-glucosidase, alpha-amylase, 4-nitrophenyl α-D-glucopyranoside (pNPG), sodium hydroxide, acetate buffer (pH 5.25), ferrous sulphate, ferrozine, potassium ferricyanide, trichloroacetic acid, ferric chloride, 3,5-dinitrosalicylic acid were purchased from Sigma Aldrich (Germany). Dimethyl sulphoxide (DMSO), methanol, ethanol, hydrochloric acid were purchased from Merck (Germany). The water used in this study was ultrapure water generated with Milli-Q PLUS (Millipore Corporation).

Preparation and analysis of the extracts

Morus alba and *Morus nigra* leaves were collected from their natural habitat in Iasi (Coordinates 47°9′24″N 27°29′10″E), Romania, in May 2022. Vegetal samples were air-dried and were ground with an IKAA1 analytical mill. Voucher specimens are deposited at the Department of Pharmacognosy, Faculty of Pharmacy, "Grigore T. Popa" University of Medicine and Pharmacy from Iasi, Romania.

Preparation of aqueous extract: 10 g of dried and powdered leaves were extracted twice with 150 mL boiling distilled water and was maintained 20 minutes to 80° C. After cooling the extract was filtered on Whatman filter paper no.1 and the combined extracts were lyophilized in order to obtained lyophilizate that was used for analysis (14).

Preparation of the ethanol-water extract: 2 g of dried and powdered leaves were extracted with 2 x 50 mL ethanol-water 70:30 on water bath, at reflux, for 45 minutes. The extracts were filtered and completed to 100 mL using the same solvent. The extracts were dried using a rotary evaporator.

Dried extracts were solved in dimethyl sulfoxide (for ethanol-water extract) or water (for lyophilizate extract) in order to obtain solutions with concentrations between 0.0097 and 20 mg/ml that have been

used for the tests (14). We obtained and analyzed four extracts: MAE (*Morus alba* ethanol-water extract), MAA (*Morus alba* aqueous extract), MNE (*Morus nigra* ethanol-water extract), MNA (*Morus nigra* aqueous extract).

Determination of total phenols content: 1 ml diluted solutions of extracts were mixed with 1 mL of Folin-Ciocâlteu's Reagent, allowed to stand for 5 minutes at 25ºC before adding solution of sodium carbonate 20%. For 120 minutes, the samples were kept in the dark, before measuring the absorbance at 750 nm. Gallic acid was used as standard. The results were expressed as gallic acid equivalents (GAE) (mg/1 g dry extract) (15).

Determination of flavonoids content: 0.25 mL diluted extract were mixed with 1.525 mL distilled water, 0.075 mL solution sodium nitrite 5%- and 0.15-mL solution aluminum chloride 10%. After 5 minutes 0.5 mL solution sodium hydroxide 1M was added and the absorbance of solution was determined at 510 nm against sample blank. The results were expressed as rutoside equivalents (mg RE/1 g dried extract) (16).

Antioxidants and enzyme inhibition tests

Antioxidant activity of the extracts was determined by iron chelating test, ferric ions reducing test, lipoxygenase inhibition.

Iron chelating test: 0.2 mL diluted extracts, 0.74 mL 0.1 M acetate buffer (pH 5.25), 0.02 mL 2 mM ferrous sulphate solution and 0.04 mL of 5 mM ferrozine solution were mixed. After 10 in the dark medium the absorbance of the solutions was determined at 532 nm. The iron chelating activity was determined using the following formula: Activity % = 100 × (A_C – A_S)/(A_C), where A_C is the absorbance of the control solution (without chelating compounds) and A_S is the absorbance of the sample solution. Rutoside was used as positive control. The assay was conducted in triplicate. The EC_{50} was calculated for each extract that present a chelating activity over 50% and is expressed as mg sample/mL final solution (17).

Ferric ions reducing test: 0.5 mL diluted extracts, 0.5 mL phosphate buffer (0.2 M, pH 6.6) and 0.5 mL potassium ferricyanide solution 1% were mixed and maintained at 50ºC for 20 minutes. After cooling the solutions were mixed with trichloroacetic acid solution 10%, centrifuged at 3,000 rpm, and an aliquot of the upper layer was mixed with distilled water and ferric chloride solution 1%. The absorbance of solutions was determined at 700 nm. Rutoside was used as positive control (18).

Lipoxygenase inhibition test: 0.05 mL diluted extracts were mixed with 0.05 mL lipoxygenase buffer solution (pH 9) and kept for 10 minutes at room temperature. Afterwards, 2 mL linoleic acid buffer solution 0.16 mM (pH 9) were added. The absorbance was determined at 234 nm for 120 seconds. The results were calculated using the following formula: % activity = (A_E – A_{ES}) x 100/A_E, where A_E is the difference between the absorbance of the enzyme solution alone after 90 seconds and the absorbance of the same solution after 30 seconds and A_{ES} is the difference between the absorbance of the enzyme solution mixed with the sample after 90 seconds and the absorbance of the same solution after 30 seconds (19). Rutoside was used as positive control.

The capacity of extracts to control carbohydrates digestion was evaluated by alpha-amylase and alpha-glucosidase inhibition tests.

Alpha-amylase inhibition test: 0.04 mL diluted extracts were mixed with 20 mM phosphate buffer pH 6.7, 0.08 mL alpha-amylase solution (2 UI/mL), 0.2 mL 0.5% starch solution in 20 mM phosphate buffer pH 6.7 and were maintained at 37°C for 10 minutes. The reaction was stopped with 0.32 mL 96 mM 3,5-dinitrosalicylic acid and the mixture was maintained at 100°C for 15 minutes. After cooling was added distilled water and the absorbance of each solution was measured at 540 nm. The percentage of alpha-amylase inhibition was calculated as follows: $(1–A_C/A_S) \times 100$, where A_C is the absorbance of control and A_S is the absorbance of the sample. Acarbose was used as positive control (20).

Alpha-glucosidase inhibition test: 0.1 mL diluted extracts were mixed with alpha-glucosidase (1 U/mL), phosphate buffer, pH 7.0, and were maintained at 37°C for 5 minutes. After that 0.25 mL p-nitrophenyl-alpha-D-glucopyranoside solution was added and the mixture was maintained again at 37°C for 10 minutes. The absorbance of the final solution was determined at 405 nm. The percent of alpha-glucosidase inhibition was calculated as follows: $(1–A_C/A_S) \times 100$, where A_C is the absorbance of control and A_S is the absorbance of samples containing extracts. The inhibitory concentration of the extract required to inhibit the activity of the enzyme by 50% (EC_{50}) was calculated by regression analysis. Acarbose was used as positive control (21).

For each test, the concentration of the extract required to obtain a positive effect over 50% (EC_{50}) was calculated by regression analysis and expressed as µg sample/mL final solution.

Statistical analysis: all determination were conducted in triplicate and the results are expressed as mean ± standard deviation. Statistical analysis of the data was performed using ANOVA test.

RESULTS

Radojkovi and co-workers investigated the effects of various extraction parameters on the extraction yield of phenolic compounds and the antioxidant activity of the extracts from *Morus nigra* leaves using Response Surface Methodology (RSM). It was shown that three factors, namely ethanol concentration, temperature and liquid/solid ratio have the most significant influence (22). Starting with the data collected from this specialty field, we have chosen to do extractions using 70% ethanol and boiling distilled water.

Morus sp. extracts can be obtained through different extraction processes such as: pressurized liquid technique, supercritical-fluid, microware-assisted, ultrasound-assisted, in the solid phase, but the solid-liquid extraction is the most advantageous compared to other methods due to the reduced processing and the convenience of operation (23, 24, 25). These methods often use toxic solvents and may require an evaporation or concentration step. Large amounts of solvents are needed, which could be hazardous to the human health and the environment, difficult and time-consuming to completely remove. Furthermore, the possibility of thermal degradation of the bioactive ingredients cannot be neglected due to the high temperatures of the solvents during the prolonged extraction time. Considering these conditions and also the fact that in traditional medicine are used the aqueous extracts from the *Morus sp*. leaves, we decided to realize and analyze the aqueous extracts resulted after concentration through lyophilization.

Chemical composition of extracts

The total phenolic contents of extracts from *Morus alba* and *Morus nigra* leaves ranged from 46.80 to 95.20 mg GAE/g (tab. I). Ethanol-water extracts obtained from *Morus* leaves contain more polyphenols and flavonoids than aqueous extracts. This is explained by the ability of ethanol-water solution to extracts some lipophilic compounds from the vegetal samples. In traditional medicine *Morus* leaves aqueous extracts are used for diabetic patients and the ratio between vegetal material and water is lower than that was used by us to prepare the aqueous extracts.

These results were in accordance with those reported by other researchers that also found higher total polyphenolic content for *M. nigra* than for *M. alba* (26).

The variation of phenolic compounds in the leaves extracts depends on many factors, such as degree of maturity at harvest, genetic differences and environmental conditions but also the solvent type, extraction time, temperature in the different extraction procedures and analytical methods used in each work (7).

Suriyaprom and coworkers observed that the aqueous extracts of *Morus* leaves exhibited the high antioxidant and antibacterial activity, which was associated with a higher phenolic and anthocyanin content (27).

MAE - *Morus alba* ethanol-water extract; MAA - *Morus alba* aqueous extract.
MNE - *Morus nigra* ethanol-water extract; MNA - *Morus nigra* aqueous extract;
[a]p <0.0001 (ethanol-water extract *vs.* aqueous extract)

Yazdankhah and co-workers investigated total phenol content, antioxidant activity and anthocyanin components of ethanol-water *Morus nigra* extract and they noticed that *Morus nigra* extract had a good antioxidant potential and the main detected anthocyanin by HPLC method was cyanidin-3-glucoside (28).

The assessment of antioxidant activity

Iron 2+ is essential for human body but at the same time, depending on concentration could be involved in toxic processes. This ion participates in toxic conversion of hydrogen peroxide and superoxide anion to hydroxyl radical that affects proteins, nucleic acids and lipids by oxidation (29). Uncontrolled oxidative processes induce different pathological conditions and increase the risk for cardiovascular disease, diabetes, inflammatory state, and cancer. Natural compounds that have the ability to block iron 2+ will control oxidative processes and will reduce the intensity of oxidative stress.

Morus sp. extracts have the ability to block iron ions depending on extract concentration. Ethanol-water extracts from *Morus nigra* are seven times more potent than lyophilized extracts from the same species. For Morus alba extracts, the ethanol-water are four times more potent (fig. 1).

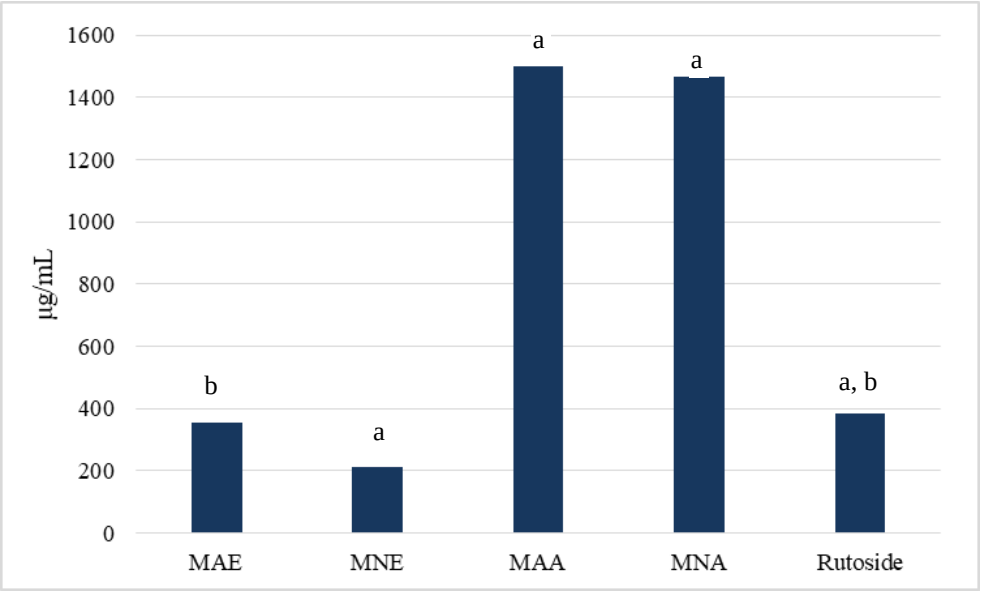

Fig. 1. The variation of the EC_{50} values of the *Morus sp*. extracts in the iron chelating test MAE - *Morus alba* ethanol-water extract; MAA - *Morus alba* aqueous extract; MNE - *Morus nigra* ethanol-water extract; MNA - *Morus nigra* aqueous extract; sample *vs.* positive control - a: p<0.0001 extremely statistically significant; b: p < 0.05 statistically significant

Compared to the Rutoside used as a positive control, the ethanol-water extracts have a greater capacity to chelate the ferrous ion (fig. 2), which suggests the involvement in this process of other compounds present in the plant extracts (30).

Iron 3+ is another form of iron that participates in redox processes in the human body. The high ratio Fe^{3+}/Fe^{2+} induced oxidative stress (31). Compounds with hydroxyl groups have the ability to transform Fe^{3+} to Fe^{2+} and finally to chelate Fe^{2+}.

15-lipoxygenase is a non-heme iron enzyme that catalyze the oxidation of unsaturated fatty acids to peroxides involved in physiological and pathological processes. High rate of its activity is correlated with inflammation and uncontrolled degradation of lipids and membrane structures.

The activity of enzyme can be modified until it is blocked by compounds that reduce Fe^{3+} to Fe^{2+}, chelate Fe^{2+} or modify the three-dimensional structure of the enzyme. Organic compounds such as polyphenols and flavonoids have the ability to release protons and electrons that modify the enzyme activity (32).

All extracts influence the enzyme activity in a concentration-dependent manner (fig. 3). The less active is *Morus alba* aqueous extract with maximum inhibition of 47.91±0.88%.

Morus alba ethanol-water extract has the most important effect on lipoxygenase inhibition test, but this extract doesn't contain the most important quantities of polyphenols or flavonoids. This effect sustains the necessity to establish the chemical composition of extracts and to evaluate the interactions between the most important groups of active compounds and enzyme.

The ability to control carbohydrates digestion

Alpha-amylase and alpha-glucosidase are the most important digestive enzymes for carbohydrates transformations in the small intestine. All compounds that have the ability to control these enzymes will control the value of postprandial hyperglycemia by lowering carbohydrates hydrolysis and glucose absorption.

Long-term hyperglycemia is difficult to control, and this phenomenon is correlated with high risk for diabetes and obesity. Some studies suggest the necessity to con-

trol these enzymes in order to control diabetes onset (33).

The values of EC_{50} determined for alpha-amylase and alpha-glucosidase inhibition tests are presented in figures 4 and 5.

All extracts reduce alpha amylase activity with more important effects for ethanol-water extracts compared to aqueous ones. The EC50 values determined for the ethanol-water extracts are approximately three times lower compared to those for acarbose.

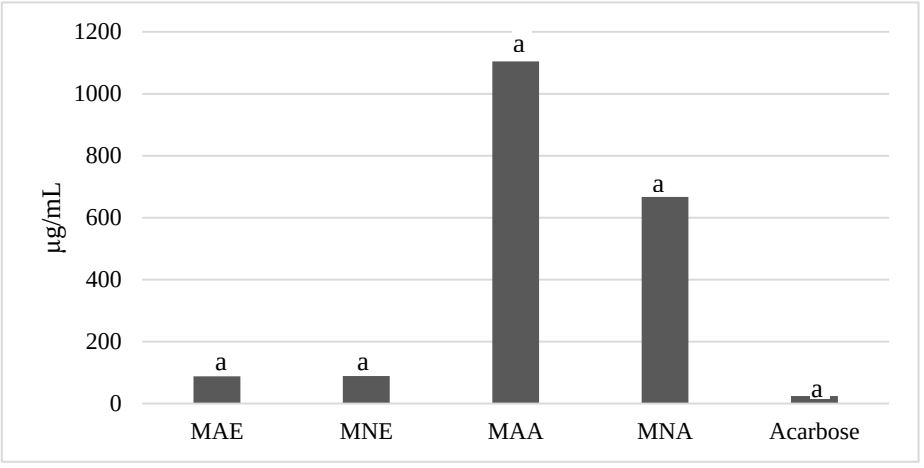

Fig. 4. The variation of the EC_{50} values of the *Morus sp.* extracts in alpha-amylase inhibition test. DISCUSSION

The extracts control alpha-glucosidase activity in special manner, the effect is not so important until concentration below 0.625 mg/mL and reach almost total inhibition at concentration above 10 mg/mL for ethanol-water extracts.

In the alpha-amylase inhibition test, the ethanol-water extract from both species have similar effects. It also observed that the effect of the same extracts is different in the alpha-glucosidase inhibition test with a stronger effect for extracts from *Morus nigra*. The enzyme inhibition effects are correlated with polyphenols content. Extracts from the two species can inhibit enzymes differently, so Eruygur and colleagues observed a more intense action for *Morus alba* in the alpha-glucosidase inhibition test and for *Morus nigra* in the alpha-amylase inhibition test (34).

Morus sp. extracts control digestive enzymes like acarbose that is one of the most important drugs used for this effect. The use of acarbose is limited by therapeutic compliance due to side effects such as flatulence, diarrhea, bloating and liver toxicity. This side effects are induced by the aggressive action of acarbose on enzymes, for this reason moderate inhibitors are more acceptable by the patients (35).

Another interaction between active compounds from extracts is with starch that is the substrate for alpha-amylase. Plant extracts rich on polyphenolic compounds modify the physicochemical properties of starch molecule and reduce it digestibility on the small intestine (36). Polyphenols interact with starch structure and realize hydrogen bonds with hydroxyl groups of this (37).

Depends on concentration isolated polyphenol carboxylic acids such as gallic acid can increase starch transformation by reducing the value of pH. The use of these acids in pharmaceutical forms is limited by this effect (38).

Chlorogenic acid, rutin, isoquercitrin, and quercitrin are present in *Morus alba* leaves and have been shown to have hypoglycemic properties and an ameliorating effect on diabetic nephropathy, insulin resistance, and dyslipidemia in rats. In extensive work, Hunyadi and his collaborators have demonstrated that chlorogenic acid and rutin play a major role in the in vivo anti-diabetic activity of *Morus alba* leaf extract (39). The preliminary analysis by HPLC highlights the presence of polyphenols in our samples, thus in future research the quantification of these compounds and the highlighting of their biological implications will be conducted

The obtained results allow the establishment of correlations between the extraction conditions, the composition of the extracts and their biological actions. The results also support the use of extracts for in vivo studies, with the aim of highlighting their ability to control blood glucose levels.

CONCLUSIONS

Morus leaves contain a variety of polyphenols that have antioxidant effects and free radical scavenging *in vitro*.

The analyzed extracts have an antioxidant activity and capacity of controlling the enzymes involved in the digestion of the carbohydrates, but in order to raise the therapeutically efficiency and also to reach optimal effects by administrating lower quantities of vegetal extracts, it’s necessary to fraction these extracts and an advanced separation of the compounds with important biological effects.

DIFFICULTIES IN IMPLEMENTING THE DIETARY REGIMEN IN OBESE LITHIASIC PATIENTS (Abstract): Obesity and kidney stones are two related diseases. We initiated a program that involved monitoring patients who had an episode of urinary lithiasis in the past three months and providing a personalized diet regimen adapted to the type of kidney stone. **Material and methods:** Of the 687 patients diagnosed with urinary lithiasis and obesity between January 2021 and February 2023, only 243 accepted a first evaluation. We enrolled 115 females and 128 males, aged between 32 and 74 years, whit a mean age of 54.51 (SD+/- 11.13). **Results:** Of the 243 patients who accepted the first evaluation, 49.79% (n=121) followed the recommended plan, which included a diet, drinking at least 2.5 liters of water daily, and frequent measurement of urinary pH. Of these, 34.97% (n=85) patients measured their urinary pH twice daily, while 10.69% (n=26) measured it only once in the morning. It is important to note that every patient who adhered to the dietary and urological recommendations was able to sustain an average weight reduction rate of roughly 1 kg/week. Additionally, body weight and urine pH were negatively related, with larger body weights corresponding to lower pH readings. A bodyweight surplus of less than 30 kg had no impact on lipid constants, but over this amount, the average went over the upper limit. Working with obese urolithiasis patients might be difficult, but it's essential to get results. **Conclusions:** However, patients who adhered to the guidelines and the weight reduction program had positive outcomes, which encouraged us to stick with this strategy. Additionally, we discovered that no patient gained weight again throughout a time spanning from 4 months to 2 years while under intensive surveillance and counseling. This proves that our weight loss plan is successful and long-lasting. **Keywords**: KIDNEY STONES, OBESITY, WEIGHT LOSS, DIET.

Obesity is a complex multifactorial disease, defined as an abnormal or excessive accumulation of adipose tissue that causes a major health risk (1). It represents a serious global problem because it significantly increases morbidity and mortality due to the physio-pathological and metabolic implications for cardiovascular, pulmonary,

rheumatological, and oncological conditions but also due to mental health impairment (2, 3).

Approximately 39% of adults worldwide are overweight, of which 13% are obese. (4). In the European Union, 52.7% of adults are overweight, of which 16.5% are obese. Comparatively, in Romania, the data show that approximately 58.7% are overweight, of which 10.9% are obese (4).

On the other hand, urinary lithiasis is a common multifactorial disease in the general population, with a global incidence of approximately 10-11% (5). Different studies indicate that obesity increases the risk of developing and recurrence of urinary stones, with a significant association between BMI, abdominal circumference, and the risk of kidney stones, both for adult and young populations (6, 7). The relationship between obesity and lithiasis is complex and can be explained by multiple mechanisms. People with obesity are prone to excrete higher calcium and uric acid concentrations.

Trying a multidisciplinary approach to the complex problem of binom obesity - lithiasis, we encountered numerous difficulties that we tried to overcome. We aimed to evaluate the compliance of obese lithiasic patients to the lifestyle changes program

MATERIAL AND METHODS

We initiated at the Urology Clinic of "Dr. C.I. Parhon" Clinical Hospital in Iasi a Program for Evaluating and Monitoring Lithiasic Patients with Obesity (PEMLPO) The inclusion criteria include patients under 75 years of age with BMI>24.99 and diagnosed with at least one episode of urinary lithiasis. The program involved monitoring patients who had an episode of urinary lithiasis in the past three months and providing a personalized diet regimen adapted to the type of kidney stone.

Patients were excluded from the program if they were uncooperative, noncompliant, refused to be included, had various forms of dementia/oligophrenia, were pregnant, had associated tumor pathology, or opted for specialized nutritional and medical counseling in another medical center.

Patients were clinically and anthropometrically evaluated at the initial examination, laboratory tests were performed, renal and vesical ultrasound was performed, and a KUB was performed if necessary. After analyzing the dietary pattern and macro- and micronutrient requirements, a personalized diet was developed based on the body's needs, offering foods with low concentrations of oxalates/urates or that reduce the inflammatory syndrome.

Based on the medical history and interpretation of paraclinical results, other diseases associated with urinary lithiasis were identified (endometrial neoplasm, ovarian neoplasm, hypertension, diabetes, dyslipidemia, irritable bowel syndrome), and patients were referred to specialized medical consultations.

Patients received written recommendations regarding dietary restrictions and conduct specific to the type of stone, paraclinical data results, and a personalized nutritional plan for 7-14 days. The nutritional plans were calculated and verified based on the ideal weight according to the modified Lorentz formula for age.

The nutritional plans were developed in a specialized program that respected the proportions of macronutrients (protein 15-20%, fat 25-30%, carbohydrates 50-55%) and the requirement of micronutrients (vit-

amins and minerals), as well as the requirement for water and physical exercise (ideally outdoors). Patients were asked to send pictures of their three main meals and two daily snacks and additional information about blood pressure, blood glucose, urinary pH, and regular body weight measurements to a dietitian. After the first two weeks of the nutritional plan, each patient received a personalized physical exercise program based on age and sex. To ensure adequate monitoring, patients were regularly re-evaluated, and nutritional plans were adjusted based on the new measurements.

RESULTS

Between January 2021 and February 2023, we identified 687 patients diagnosed with urinary lithiasis and obesity who were invited to be included in PELO. Out of these patients, 223 accepted a first evaluation. At the same time, 444 declined the invitation due to reasons such as a lack of interest in losing weight, not considering obesity as a disease, not wanting to follow a dietary program, not having the time and desire to be monitored for a long period, living far away from Iasi, or residing in rural areas.

We enrolled 105 females and 118 males, aged between 32 and 74 years, whit a mean age of 54.51 (SD+/- 11.13). Of the 223 patients who accepted the first evaluation, 49.77% (n=111) followed the recommended plan, which included a diet, drinking at least 2.5 liters of water daily, and frequent measurement of urinary pH. Of these, 76.57% (n=85) patients measured their urinary pH twice daily, while 23.42% (n=26) measured it only once in the morning. Additionally, 39 patients followed only the dietary plan and frequently communicated with the nutritionist through phone or messages. At the same time, 17.11% (n= 19) monitored their urinary pH carefully but did not adhere to the recommended dietary plan and consumed between 2-2.5 liters of water daily.

On the other hand, 54 patients only came for the first evaluation. They withdrew from the program later, citing lack of time, demanding work schedules, or difficulty following a balanced diet. The majority of patients had a surplus body weight of over 20 kg and were between 31-70 years old, with the highest number of patients aged between 51-60 years old.

Regarding comorbidities, out of the 223 enrolled patients, 41 (18.39%) were diagnosed with type 2 diabetes. At the same time, nine were found to have altered basal glycemia during the initial paraclinical evaluation, and five were put on Metformin treatment. Out of the 41 patients with diabetes, 29 collaborated with the program. Furthermore, 49 patients were diagnosed with hypertension for which they received medical treatment, 46 had dyslipidemia, and 68 had hyperuricemia.

During the initial evaluation, several comorbidities were discovered, such as one case of endometrial cancer, one case of ovarian cancer, four cases of irritable bowel syndrome, and seven cases of hypertension. Five patients were diagnosed with type 2 diabetes and referred to a specialist for further consultation.

Regarding the evolution of known comorbidities, 11 patients under oral antidiabetic treatment and following dietary recommendations normalized their glycemic values, while five patients reduced their medication doses under direct supervision from their diabetologist. Of the 49 hypertensive patients, 23 were able to re-

duce their medication doses under cardiologist supervision as their blood pressure values improved with weight loss. Among the 46 patients with dyslipidemia, 28 stopped taking their lipid-lowering medication under medical supervision as their values improved, while 9 reduced their medication doses. Moreover, out of the 68 patients with hyperuricemia, 29 normalized their serum uric acid values. Finally, one patient with hepatic fibrosis resulting from chronic infection with hepatitis C improved from F2 to F1 according to the results of their periodic FibroScan.

It is worth saying that all patients who followed the recommended nutritional and urological guidelines were able to maintain an average weight loss rate of about 1 kg/week. Furthermore, urinary pH was inversely proportional to body weight, meaning that the higher the body weight, the lower the urinary pH values. However, lipid constants were unaffected by a bodyweight surplus of less than 30 kg, while above this value, the average exceeded the upper limit.

Of all the patients who collaborated with us, 45 have reached their ideal weight, +/- 2 kilos. However, the most satisfying aspect was that they have managed to maintain it until now.

DISCUSSION

Although there are several interventions available to manage obesity and prevent urinary stones, their effectiveness is highly dependent on patient engagement and adherence. Our study investigated the difficulties in implementing a dietary regimen in obese lithiasic patients. The findings reveal several important challenges that healthcare providers and patients face in achieving the two main goals: normal weight and nonrecurrence of kidney stones.

One major obstacle is the difficulty in collaborating with obese lithiasic patients. Patients who struggle with obesity often have difficulty adhering to dietary recommendations and may lack the motivation to make lifestyle changes. As a result, healthcare providers must employ creative strategies to engage patients and encourage compliance with dietary guidelines.

Additionally, healthcare providers must address the psychological barriers patients may face in adhering to a dietary regimen. Patients may struggle with feelings of deprivation or boredom when following a restricted diet, which can lead to noncompliance or binge eating. Nutritionists can address these challenges by providing patient education, support, and motivation to maintain adherence to the dietary regimen.

In a large South Korean cohort, Lim *et al.* found that approximately 27% of patients who had undergone the initial evaluation were determined to take serious measures to lose weight (8). This is an optimistic result because in our study, only 17% fully complied with the recommendations and the diet and can be considered to have taken serious measures to lose weight. Moreover, the authors reported that 84% of patients considered obesity to be an important factor in their general health, but some patients who refused enrollment indicated that they did not consider obesity to be a problem. The authors propose that patients can be persuaded to acknowledge the true consequences of obesity through informative and easy-to-understand materials (8). The study also found that 78% of patients had made at least one serious attempt to lose weight in the past, but they did so on their own, without the support of

a monitoring program. In our study, only 16.8% of obese patients agreed to be enrolled. This lack of support may have contributed to their failure and reduced their confidence in future attempts. Therefore, the article suggests that providing patients with the necessary support may help improve their chances of success (8).

We think patients can achieve weight loss through adherence to different diets, but the type of diet should be chosen based on the individual's needs and preferences to which the type of twist should be added.

In conducting studies and implementing weight loss programs, enrolling participants is difficult. As demonstrated by Rounds *et al*., participation in weight loss programs is often low, with only a small percentage of eligible individuals opting to enroll. This highlights the need for strategies to increase enrollment and engagement, such as targeted outreach efforts and tailored interventions based on patient preferences (9).

Another study, Caterson *et al.* showed that people with obesity are aware of their health problems and that many are motivated to lose weight. However, there is a difference between perception and reality regarding obesity and weight loss. For example, while 88% of patients consider obesity a disease and 46% are concerned about the impact of excess weight on their health, only 48% are motivated to lose weight (10).

The yo-yo effects represent another issue regarding weight loss and maintaining weight loss. These refer to repeated cycles of weight loss and weight gain, which can have a negative impact on physical and psychological health. Although weight loss is important for overall health, it is important to provide patients with information and support to maintain long-term weight loss and avoid the yo-yo effect (11).

Another challenge is the need to address the complex nutritional needs of obese lithiasic patients while promoting weight loss. Weight loss is a critical component of a successful dietary regimen for obese lithiasic patients, as excess body weight can contribute to the formation of kidney stones. However, losing weight can be difficult, particularly for patients with failed weight loss attempts.

One strategy to address this challenge is reducing calorie intake while ensuring that patients receive adequate nutrients. This can be accomplished through a diet high in fruits, vegetables, and whole grains while limiting high-fat and high-sugar foods.

A study by Shai *et al.* aimed to determine the efficacy and safety of different types of diets for weight loss. The study included 322 obese individuals, and it was conducted over two years. The study found that the adherence rate to the diet was high, and the effect on glycemic control was better with the Mediterranean diet, while the effect on lipid levels was better with the low-carbohydrate diet (12). Tuomilehto *et al*. aimed to prevent type 2 diabetes by making changes to diet and lifestyle. The study included 522 individuals, and the incidence of diabetes was reduced by 58% through changes to diet and lifestyle (13).

In our program, 11 out of 26 diabetic patients were able to normalize their blood glucose levels, and five others were able to achieve significant reductions in their blood glucose levels. This shows that the implementation of lifestyle changes can help prevent and manage diabetes.

In a relatively large cohort, Borghi *et al.* identified an increased urinary volume as a factor that can reduce the risk of develop-

ing kidney stones. The study included 300 patients, and it was found that an increased water intake can help prevent the recurrence of kidney stones (14). According to Siener *et al*., a vegetarian diet that promotes urine alkalization and thus increases pH reduces the risk of uric acid stone formation (15). It is important to avoid foods with high oxalate concentrations, regardless of their type: spinach, nuts, chocolate, or sweet potatoes. Additionally, we need to differentiate between vegetarian and vegan diets, the latter being associated with uric acid stones due to hyperuricemia (16). Another dietary aspect to consider is calcium intake, which reduces the risk of stone formation. Therefore, milk and dairy products are recommended (17).

In patients with calcium phosphate stones which often develops in alkaline urine, the goals of nutritional therapy were to acidify the urine and reduce the intake of calcium phosphates. In such cases, we implemented a hypocaloric diet based on white bread, bran bread, muffins, dried fruits, pumpkin puree, vegetable oils, fruit jelly, and meat (poultry, fish). To reduce the intake of phosphates, we excluded foods such as smoked meat and products (sausages), dairy and cheese, pickles, marinades, coffee, tea, and canned food. We also contraindicated alcohol and food consumption. One aspect that requires further study is the use of phosphates as food additives (calcium phosphate - E341). Although approved by the European Union, they could contribute to the development of stones. Further studies are needed to evaluate this risk. The macronutrient ratio was subsequently adjusted individually (18).

The dietician developed a balanced and varied meal plan to address the patient's preference for meat and prevent uric acid stone attacks. This plan included a variety of protein sources, including small amounts of lean meat (up to 100 g per day) and protein-rich plant alternatives such as legumes, nuts, and seeds. Larger portions of vegetables, salads, and whole grains must accompany meat. By avoiding foods high in purines, such as animal organs and certain types of fish and seafood (Sardines in oil - about 480 mg of purines, Anchovies - about 410 mg of purines, Herring - about 370 mg of purines, Mussels - about 350 mg of purines, Fresh sardines - about 320 mg of purines, Squid - about 260 mg of purines, Oysters - about 230 mg of purines, Octopus - about 220 mg of purines), the patient could reduce the risk of uric acid crystal formation. The patient was encouraged to choose complex carbohydrates such as whole grains, legumes, and vegetables over refined and high glycemic index carbohydrates. The diet was accompanied by the introduction of an adapted physical activity program (such as walking briskly for 30 minutes after each meal) (19).

The diet for a patient with uric acid stones should aim to reduce purine intake and increase fluid intake. According to studies, a low-purine diet can significantly decrease urinary uric acid levels and the risk of uric acid stone formation. The diet should include plenty of fruits and vegetables, whole grains, and low-fat dairy products. Protein sources should be limited to low-purine options such as chicken, fish, and tofu, while high-purine sources like red meat, organ meats, and seafood should be avoided (20). Although according to our previous data, overweight and obese patients treated in our center had the most frequent calcium oxalate kidney stones (21).

We found that some patients did not

understand the importance of adequate hydration. Our data suggest that providing information about hydration's importance can help prevent kidney stone recurrence. This is more important, taking into account that in obese patients, the efficiency of shock wave lithotripsy is relatively ineffective, and more invasive procedures should be taken into account (22). Paradoxically, a higher BMI does not seem to influence infectious complications after percutaneous lithotripsy (23).

It is essential for patients with kidney stones to consume enough water to prevent the formation of new stones or to eliminate existing ones. The recommended amount of water depends on the level of physical activity, sweating, and loss of fluids through urine. To provide patients with a deeper understanding of the role of water in eliminating and preventing the formation of kidney stones, a multidisciplinary team may be involved, including urologists, dietitians, and psychologists who can offer personalized solutions for individual patient issues.

For patients who have difficulty consuming enough water, there are several solutions. If the patient does not like the taste of water, various products can be added to change the taste, such as lemon, cucumber, mint, basil, or fruits. Patients who experience nausea or vomiting may be prescribed medication by their doctor to help alleviate symptoms that interfere with water intake. In our study, one difficulty was regarding patients with overactive bladder. We encountered 17 such patients, and after the prescription of anticholinergics, their voiding frequency was reduced to normal, allowing them to have adequate water intake.

Complying with recommendations to consume enough fluids may be challenging for patients with a busy schedules or physically demanding jobs. In this situation, patients can carry a water bottle with them and consume it during activity and take bathroom breaks during their breaks. Patients with digestive problems or a hectic lifestyle can be helped by always carrying a water bottle and setting reminders on their phones to drink water regularly.

If the patient cannot afford enough water or other hydrating drinks, alternatives such as tea, unsweetened fruit compote, and fruits and vegetables with a high-water content can be used. If the patient does not feel the need for hydration, the urologist and dietitian can investigate the reason and offer advice to encourage the patient to consume increasingly larger quantities of fluids and water-rich foods. A multidisciplinary team can provide personalized solutions for patients with kidney stones who have difficulty consuming enough fluids. It is important to recognize and address dysfunctional habits and patterns and the patient's vicious behavior to motivate them to change. In our study, of all 243 patients, 179 have maintained a daily water intake of a minimum of 2.5 liters, which is a strong suggestion that patients can understand the necessity of drinking enough water. Once a daily habit of drinking water is established, the problem of adequate hydration is less prevalent.

Our study highlights the complex challenges healthcare providers and obese lithiasic patients face in implementing a hygienic-dietary regimen.

Another issue highlighted in the literature is the relationship between obesity and urinary stone disease. Obesity is a well-established risk factor for urinary stones, likely due to changes in urine composition

and increased urinary excretion of calcium and other stone-forming substances. BMI and urine pH have an inverse relationship. Because individuals with higher BMI have a lower increase in urine pH under treatment with potassium citrate, it is suggested that most benefits may derive from weight loss (24). Alkalinization of the urine proved to be effective not only for kidney stone prophylaxis but also with similar results as alfa-blocker for some ureteral stones as medical expulsive therapy (25).

Urinary pH plays an important role in the formation of urinary stones. Therefore, monitoring and maintaining urinary pH within a certain range can help prevent the formation of urinary stones. This can be achieved through dietary changes, increasing water intake, and medications if necessary.

There are several reasons why some obese lithiasic patients do not monitor their urinary pH in our monitoring program, such as lack of awareness - some patients are not aware of the importance of urinary pH and how it affects the formation of kidney stones; cost or difficulty in obtaining urinary pH testing kits - some testing kits can be expensive or hard to obtain, which can discourage patients from using them; mismatch with their lifestyle - monitoring urinary pH can be a difficult task for some patients, especially those with a busy lifestyle; lack of motivation - some patients may be demotivated in monitoring their urinary pH because they do not see immediate benefits or do not understand the connection between pH level and stone formation.

The solutions found include explaining the importance of continuous monitoring of urinary pH and how it can help prevent the formation of urinary stones through dietary and hydration interventions; emphasizing the importance of preventing recurrence and how monitoring urinary pH can help in this regard; teaching patients how to collect urine samples and perform tests correctly; providing free kits through the PEMLPO program to eliminate reasons related to cost or availability of kits; encouraging communication with the PEMLPO team in case of monitoring problems or concerns related to results and providing personalized advice; encouraging patients to keep a journal of pH values to see progress and gain confidence in their interventions. The importance of pH monitoring is significant as pH directly reflects whether patients are indeed following dietary and fluid recommendations.

When patients have a limited budget, it is recommended that they consume healthy and nutritious foods that are cheaper. They are suggested to buy and prepare foods in larger quantities and divide them into smaller portions to save time and money. If they cannot access fresh foods due to financial or geographic limitations, patients should buy frozen vegetables, beans, fruits, and dehydrated vegetables. Information should be provided on food assistance programs and free or reduced-price food resources to assist patients with limited food needs. Additionally, it may be beneficial to collaborate with community organizations and local health centers to find personalized solutions for each patient.

A study in Australia approximated the costs of a diet for a family of four, and the presented results show that a healthy diet is 21% cheaper than an unhealthy one. However, both diets exceed the budget for families with low to very low financial situations. Additionally, discounted prices through various offers reduce costs by

approximately 3% (26).

Contributing to the failure of weight loss diets, some authors consider the endocrine response that occurs with weight loss, consisting of increased appetite and decreased satiety (27). Another aspect is sedentary behavior, both at work and in daily life, and the modernization of transportation with the use of personal vehicles also contributes to this (27)

A meta-analysis of 29 studies shows that over 50% of patients return to their initial weight within two years and over 80% within five years. The reasons are unclear, but the lack of a regular activity and exercise program is suggested (28). Another study proposes that the reason for returning to the initial weight is a too-rapid initial weight loss followed by a period of no further weight loss (29). Grodstein *et al.* concluded after a 3-year weight loss program that only 12% of patients managed to maintain at least 75% of the weight they lost, while 40% gained more than they had initially (30).

Another study led by Wing *et al.* concluded that long-term success has better outcomes for patients who maintain their lost weight for 2-5 years. The best predictor for long-term success is weight maintenance for two years. Additionally, another predictor highlighted by Wing *et al.* is represented by low levels of dietary disinhibition, or the ability of individuals to not overeat in the presence of factors such as emotional stress and appetizing foods (31).

Finally, the study found that strict supervision and counseling can ensure compliance with dietary guidelines and prevent weight gain. Patients who received regular supervision and support were able to maintain weight loss over an extended period, suggesting that ongoing support and monitoring may be necessary for long-term success.

Regarding weight loss strategies, an important aspect is to provide patients with adequate support for long-term changes in dietary and exercise habits. In this regard, multidisciplinary approaches involving physicians and specialists in nutrition and psychology can be effective in helping patients achieve and maintain weight loss goals.

CONCLUSIONS

Following this study, we have reached some important conclusions. Firstly, collaborating with obese urolithiasis patients can be challenging but crucial to achieving positive results. However, patients who followed the instructions and the weight loss program achieved good results, encouraging us to continue with this approach. We also found that under strict supervision and counseling, no patient gained weight back within a period ranging from 4 months to 2 years. This demonstrates that our weight loss program is effective and sustainable in the long term.

Finally, it is important to note that no patient who became “stone-free” after ESWL or URS experienced urolithiasis recurrence. This suggests that weight loss and an appropriate diet can be powerful tools in preventing kidney stone formation and maintaining renal health in the long term.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

CHEMICAL ASSESSMENT AND BIOLOGIC POTENTIAL OF A SPECIAL LESPEDEZA CAPITATA EXTRACT (Abstract): Secondary metabolites are natural compounds synthesized by plants as an adaptation to environmental factors. Humans use such components for the prevention and treatment of minor or mild conditions. *Lespedeza capitata* is a medicinal and melliferous plant known for its various beneficial properties (antioxidant, antiaging, antiedematous, etc.). **The objectives** of this study were to identify and quantify the secondary metabolites from a selective *L. capitata* extract. Moreover, the evaluation of the antioxidant activity was part of the present research. **Material and methods:** Identification and semi-quantification were assessed by liquid chromatography (HPLC/MS), and the total flavonoids and polyphenols were determined by spectrophotometry according to European Pharmacopeia indications. DPPH (2,2-diphenyl-1-picrylhydrazyl) assay and iron chelation test were used to establish the antioxidant putative effects of the investigated extract. **Results**: Among the identified compounds different quercetin derivatives, chlorogenic acid, and rosmarinic acid were found. The total polyphenols amounted to 174.24 mg/g GAE and flavonoids measured 95.65 mg/g rutoside equivalents. The antioxidant activity showed a good capacity to scavenge free radicals and a higher potential to chelate ferrous ions. The intensity of the effect was correlated to concentration. All in all, the investigated *L. capitata* extract demonstrated a polyphenol and flavonoid-rich content with good antioxidant potential. **Keywords**: LESPEDEZA, HPLC/MS, TOTAL POLYPHENOLS, ANTIOXIDANT ACTIVITY.

Actual living conditions are commonly related to a variable exposure to polluted environments which determines the alteration of homeostasis, the overloading of body defense mechanisms, and immunosuppression with a negative impact on health and lifestyle. In this context, plant secondary metabolites represent frequent options as antioxidants that can counteract the harmful effects of pollution and overexpression of oxygen-reactive species (1, 2, 3). The chemical conformation of flavonoids and polyphenols presents chemical patterns that allow them to donate protons to quench free radicals. Various studies confirm the antioxidant and antiradical properties of natural

and synthetic flavonoids (1, 4, 5). Moreover, certain compounds were found to have possible applications in the prevention of hypertension, vascular problems, degenerative disorders, and gastrointestinal and urinary tract diseases (6, 7, 8).

In the last decade, forage legumes come into the spotlight due to their beneficial effects on domesticated animals and the environment (phytoremediation). Hence, many plant species belonging to the Fabaceae family were screened for their rich content of polyphenols, a chemical group of metabolites, generally recognized as antioxidants (4, 5). *Lespedeza* species represent a group of wild plants used as legumes, native to the Americas and oriental countries as part of their traditional remedies. Some of the reports showed that five species (*L. tomentosa* (Thunb.) Maxim, *L. bicolor* Turcz., *L. hedysaroides* (Pall.) Kitag., *L. cyrtobotria* Miq., and *L. davurica* (Laxm.) Schindl.) are also native to Russia (5, 9, 10, 11). These species were found to contain flavonoid glycosides, lignans, sterols, alkaloids, organic acids, coumestans, and terpenoids.

Lespedeza capitata Michx. (Roundhead *Lespedeza)*, native to eastern North America and common in meadows, is an understudied legume with a tradition in folk medicine as a diuretic, anti-inflammatory, and antirheumatic both in the USA, Korea, and China. Native Americans used the roots or extracts from roots as an antidote for poisoning (5). Among the *Lespedeza* species, *L. capitata* is less studied, although extracts from leaves and stems are used for urinary tract and kidney disorders.

This study aimed to evaluate the chemical spectra of an industrial extract obtained from the aerial parts of *Lespedeza capitata* and to establish the existence of an antioxidant profile.

MATERIALS AND METHODS

Plant extract: The plant extract was obtained by direct collaboration with Vanelli company, which are single importer of *Lespedeza capitata* dried extract (4:1) in our country.

Chemical profile: The identity of the compounds found in the investigated extract was evaluated by liquid chromatography using a Transcend TLX-1 Vanquish Flex system coupled with the Orbitrap Exploris 480 high-resolution mass spectrometer and Compound Discoverer 3.3.1 software for the identification of small compounds, part of the CENEMED platform. The method used formic acid 0.1% (A) and methanol (B) in a ramp from 95:5 to 10:90 in 15 minutes, partial loop injection of 10 µL, a debit flow of 300 µL, Hypersil Gold C18 column (50 x 2.1 mm, 1.9 µm) at 40°C, and the instrument settings were electrospray ionization (ESI), negative ion mode (-p), mass range m/z from 100 to 1500 at 5 Hz frequency, negative voltage of 3.0 kV and an ionization temperature of 350°C. Integration and detection were subjected to Compound Discoverer 3.2 software for evaluation in targeted and untargeted modules. The peaks with a rating of at least 7.4 were taken into account and verified against Thermo m/z Vault, NIST, and Chem spider databases.

Total phenolic content evaluation: A colorimetric method (proposed by Singleton and Rossi) using the Folin-Ciocalteu reagent was conducted to determine the total amount of polyphenols that are capable of forming blue complexes in alkaline conditions, following a method previously described (13, 14). Gallic acid (amounts of 3-8 µg/mL) was used to obtain a calibration curve and the final results were expressed as gallic acid equivalents (GAE), quantified as milligrams of gallic acid per g dry

extract (3, 14).

Total flavonoid content evaluation: Similarly**, t**he quantification of total flavonoids used a spectrophotometric method using aluminum chloride in alkaline conditions, when flavones and their derivatives form yellow fluorescent complexes that can be measured at λ = 430 nm (12). Rutoside was used for calibration and the results were denoted as rutoside equivalents (mg rutoside/ g dry extract).

Antioxidant potential: The antioxidant effects of the extracts were evaluated by two well-known methods DPPH radical assay and iron chelation assay. For this, 2,2-diphenyl-1-picryl-hydrazyl (DPPH) was used to estimate the radical scavenging effect of *Lespedeza capitata* extract. previously described (3, 14). Ion ions (Fe^{2+}) may be complexed by ferrozine to form a magenta complex measured at 562 nm. The compounds that have an iron chelation effect block the complex formation thus resulting in a lower absorbance. All steps were followed as previously described by Nani *et al.* and Iancu *et al.* (15, 16), Ascorbic acid was used as a positive standard in both tests.

All determinations were in triplicate, and the presented results were expressed as mean ± standard deviation error.

RESULTS AND DISCUSSION

Chemical profile

The general compound profile showed the major presence of flavonoid derivatives (especially quercetin derivatives) and some polyphenol carboxylic acids [chlorogenic acid (m/z = 353.08) and rosmarinic acid (m/z = 359.16)]. The general aspect of the chromatogram is given in first figure.

Different studies indicated the major presence of similar compounds, in particular flavonoid glycosides and condensed tannins (2, 5, 6, 17), however a more elaborate chemical composition of this species is not yet available. Some of the aforementioned studies are dated before 2005. For our results, it should be taken into account that the data is strictly related to the investigated extract (which is a commercial, industrially obtained, and selective extract) and cannot comprise the full spectra of components that belong to the plant.

Total phenols amounted to almost 175 mg GAE for each gram of extract, whereas flavonoids were less (95.65) (tab. II).

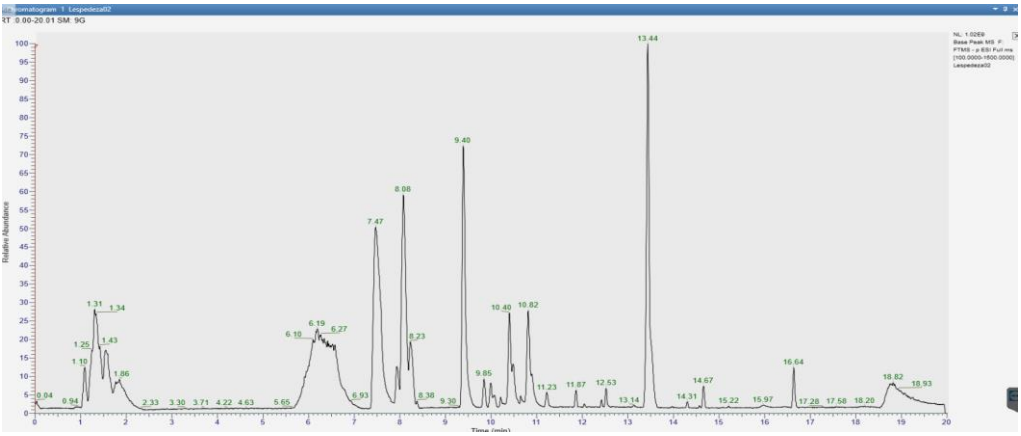

Fig. 1. General LC-ESI-MS chromatogram for *Lespedeza capitata* extract

TABLE I.

Tentative identification of the components from *Lespedeza capitata* extract

No	$[M-H]^-$ (m/z)	MS/MS (m/z)	Compounds
1	353.08	353.08, 191	Chlorogenic acid
2	179.02	341, 179, 135	Caffeic acid-3-glucoside
3	301.03	301.03, 179.0, 150.9	Quercetin-3-D-galactoside
4	515.10	515.10, 353, 191, 179	1,3-Dicaffeoylquinic acid
5	287.05	333, 287.05, 151	Dihydroluteolin
6	269.04	269.04	3,3',4'-Trihydroxyflavone syn. 5,7-Dideoxyquercetin
7	317.06	317, 299, 175	6-Methyldihydroquercetin
8	359.16	359, 161.02, 197	Rosmarinic acid

TABLE II.

Major classes of compounds for the *Lespedeza capitata* extract

Sample	Total phenols (mg gallic acid/g)	Total flavonoids (mg rutoside/g)
Lespedeza capitata	174.24± 0.63	95.65± 0.31

Results expressed as mean ± standard error of the mean (n =3) of three determinations

Despite the long tradition and use in folk and modern medicine, *Lespedeza capitata* has no scientific data available regarding the total polyphenols and flavonoids. By searching Scopus/Elsevier databases for *lespedeza AND capitata AND total AND polyphenols OR flavonoids* no matching documents were found. Nevertheless, other Lespedeza species such as Korean *L. cuneata* were proven to contain 102.7 mg gallic acid/g and 62.8 mg quercetin/g (18). Also, data on the aerial plant product (*L. bicolor*) from Pakistan indicated the presence of 3.321 mg GAE/g of dried weight and 0.148 mg/g of dried weight (19).

Antioxidant potential

The obtained data for both antioxidant tests are given in fig. 2 and are expressed as the inhibitory concentration of 50 % of DPPH radicals and iron complexes respectively.

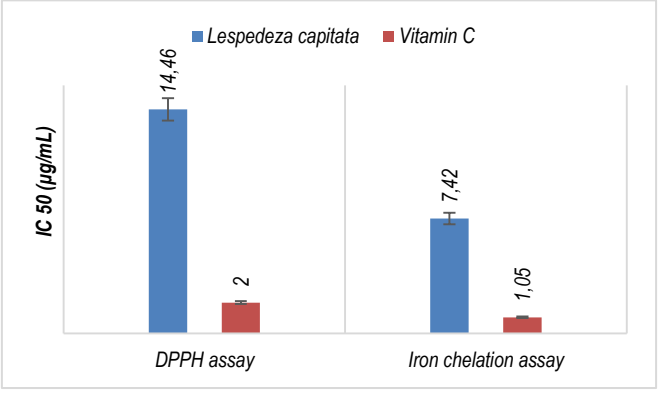

Fig. 2. Results for the antioxidants assays (represented as IC50) for *L. capitata* extract

The results indicated that the investigated extract has a lower activity than ascorbic acid used as a positive standard, however, the IC50 values were expressed in μg/mL of extract. Such amounts are extremely low and prove that the selective *L. capitata* extract has great potential as an antioxidant, but the intensity of the effect depends on the mechanism of action. The phytocomplex found in the extract exhibited twice as much activity against ferrous ions than against DPPH radicals. This is an interesting aspect since ferrous ions are involved in the Fenton reaction that generates hydroxyl radicals in living organisms, such radicals are known to be aggressive and damaging (15, 16).

Other *Lespedeza* species (*L. bicolor*) showed good antioxidant activity, with IC50 values ranging from 50 to 200 μg/mL, but the root samples were better than the aerial parts (19).

More recent research investigated the capacity of an *L. capitata* extract to inhibit collagenase activity which is related to skin cell ageing. The results showed that the extract possesses potential benefits for dermatologic use and wound healing similar to some other Brazilian plants (12).

CONCLUSIONS

Our study represents a starting point for further research in assessing the putative activity of *L. capitata*. The investigated extract is already used in some formulations (along with silymarin) as food supplements recommended for maintaining good liver and kidney functionality. The obtained results indicated a good chemical profile and an interesting antioxidant potential, especially active against ferrous ions. In conclusion, more data is still needed to confirm the actual benefits of *Lespedeza capitata*.

CONFLICT OF INTEREST

The authors declare that there is no conflict of interest.

PREDICTABILITY OF DIGITAL SET-UP IN ORTHODONTICS (Abstract): The orthodontic setup is a three-dimensional simulation that allows the teeth to be aligned in the appropriate position according to a previously established treatment plan previewing the final result. The main purpose of this study was to evaluate the accuracy of the digital orthodontic set-up by comparing it with the result of the orthodontic treatment. The secondary purpose is to compare the correlation between the parameters obtained after performing the digital setup with the analysis of the study models at the end of the orthodontic treatment. **Materials and methods:** The study models of 40 patients were digitized. In a subsequent phase, the digital set-up was performed using the BlueSky Plan software (Libertyville, IL United States) to obtain appropriate intermaxillary relations according to the treatment plan. **Results:** The intercanine and intermolar distances, and the length of the dental arches were measured both in the initial, final models, and after the set-up in order to be able to compare them. Statistically significant differences were observed between the intercanine width (p=0.007) and arch length (p=0.02) of the final models compared with the set-up models. Regarding the other evaluated parameters of the final models, although the values were decreased compared to the set-up models, the differences were not significant. **Conclusions:** the comparison made between the digital set-up and the patient's final model gives confidence in choosing the set-up as a reliable tool for treatment planning. **Keywords:** DIAGNOSTIC, DENTAL MODEL, SET-UP, INTERCANINE WIDTH.

Diagnosis, in orthodontics, as in other fields of medicine, requires the collection of a database with concrete information about the patient's main dento-alveolar problems. Important information can be obtained from direct observations, the study of the patient's photographs, radiographs, CT scans, study models, intraoral scans, but also by creating a set-up that allows simulating the alignment of the teeth following the orthodontic treatment (1, 2).

The dental field has always been in step with the developments in the world of technology. During the last century, several

revolutionary leaps that gave rise to new theories and hypotheses were introduced. The last important discovery can be considered the use of CAD-CAM systems (3, 4).

The use of the intraoral scanner in the daily routine offers the possibility of obtaining 3D models of the dental arches with impeccable precision. The use of these 3D models has made it possible to modify the diagnostic approach, improving and simplifying classic orthodontic analyses, thus allowing various virtual simulations (5, 6).

The biggest revolution introduced by the digital set-up consists in the fact that it allows the treatment to begin by previewing its "end", orienting the practitioner strictly in the direction of the desired result (7, 8).

Set-up in orthodontics

Until the recent past, the focus in orthodontic treatment planning was mainly based on the analysis of photographs, models and profile teleradiograph. The contemporary approach involves a much more detailed clinical examination, where many aspects of the treatment plan are discovered through a functional and aesthetic assessment of the patient. (9)

The orthodontic set-up represents a three-dimensional simulation of the orthodontic teeth movement based on specific treatment objectives. It is thus a valuable diagnostic tool that allows the comparison of several proposed treatment plans, highlighting the risks and benefits of each one, indicating the possible need for surgical interventions or dental extractions, thus facilitating communication with the patient (9,10).

The main advantage of this procedure is that it allows the clinician to assess whether the planned treatment plan is really viable for that case (11, 12).

Digital Set-up

Over the years, with the advancement of the digital age, the orthodontic set-up has gone through several phases of evolution (13). Now we can talk about the existence of two types of set-up: classic and digital. So, the "laboratory work" in which the teeth were cut and aligned with the help of wax, is now reduced to some virtual segmentation techniques (14, 15).

Although it presents multiple advantages, the digital set-up has a long learning curve, requiring an additional effort of the practitioner. In addition, most of the software allows the strict evaluation of the dental crown movement, without considering the position and condition of the roots (16, 17).

Classic or Digital, it is universally accepted that the setup makes the treatment plan less speculative, providing the clinician with reliable information that can reduce biological damage to the patient.

OBJECTIVES

The main purpose of this study was to evaluate the precision of the digital orthodontic set-up by comparing it with the result of the orthodontic treatment.

The secondary aim was to compare and correlate the parameters obtained after performing the digital set-up with the analysis of the models after the completion of the orthodontic treatment. Thus, comparatively analyzed the intercanine, intermolar distance and the length of the dental arches for both the upper and lower arches.

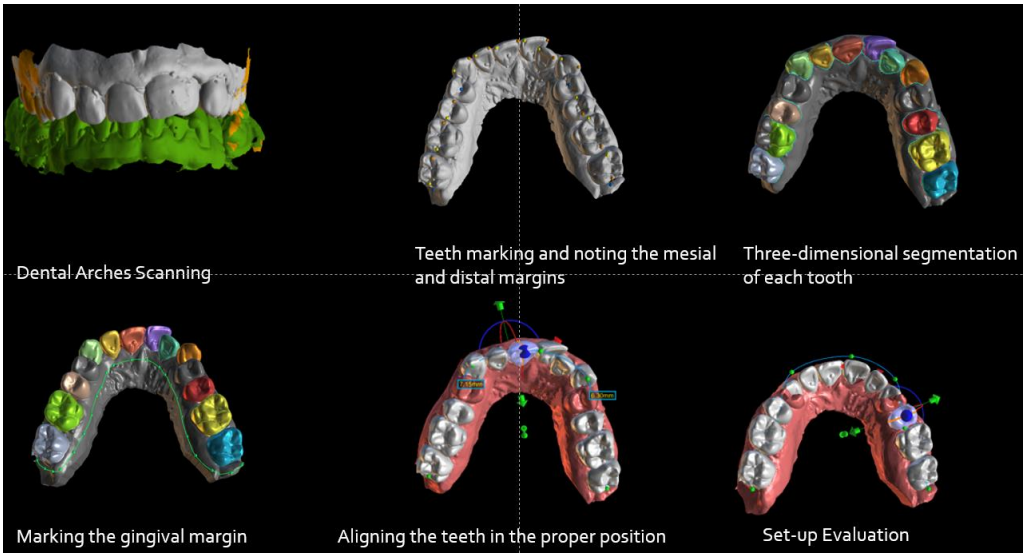

Fig. 1 Digital Set-Up Step by Step

MATERIALS AND METHODS

To achieve the proposed objectives, we studied a sample consisting of 80 conventional study models (40 initial models and 40 final models after the orthodontic treatment) and 40 digital models. Patients were treated during the years 2016-2021 at the Dental Clinic "Natural Smile by Dr. Pop", coming from both urban and rural areas. The inclusion criteria for our study were as follow:

1. The patient has completed the orthodontic treatment;

2. The treatment required the extraction of one permanent tooth from each hemi arcade;

3. Permanent or mixed dentition at the beginning of treatment;

4. The treatment does not require major prosthetic and surgical interventions;

5. The patient does not need orthognathic surgery;

6. Patient models are in proper condition and have been manufactured correctly.

Thus, following a rigorous selection, 40 patients who m*et all* these requirements were included in the study. The main goal after the orthodontic treatment, as well as the digital set-ups, was to obtain:

- correct occlusal relationships, respecting the fundamental principles of occlusion,
- arch of appropriate shape,
- cusp-pit occlusal contacts,
- overbite and overjet within acceptable limits,
- appropriate relationships of the inclined occlusal plane at the level of molars and premolars,
- appropriate sagittal Spee and transverse Wilson curves.

The initial and final models were scanned using the Medit i500 (Seoul, South Korea) high-precision scanner which uses a laser beam and intraoral cameras, which allowed them to be saved in STL (Standard Triangle Language) formal. Next, the digital set-up was carried out using the BlueSky Plan software, using the "Orthodontics" section.

The steps followed are approximately the same for all the software, with small differences depending on the complexity of the analyzed data (fig.1):

1. Scanning dental arches or study models
2. Entering data and scans in the setup software
3. Calling the teeth and marking their mesial and distal ends
4. Three-dimensional segmentation of each tooth
5. Aligning the teeth in the proper position
6. Evaluation of the setup

The teeth were moved to their ideal position according to the treatment plan, considering the limits imposed and the teeth considered extracted achieving stable and functionally correct interocclusal relationships. At the end, the set-up was saved as digital models, to allow the measurements necessary for the study to be carried out and then the comparison with the data obtained from the analysis of the final models (fig. 2).

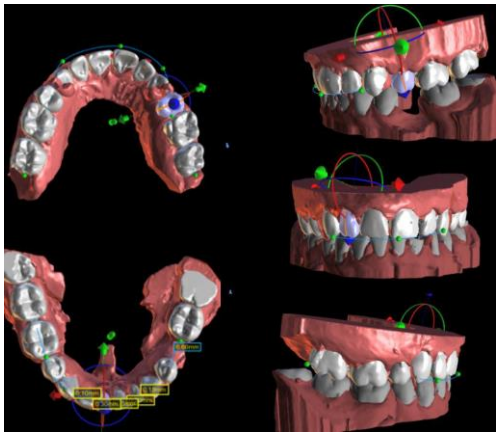

Fig. 2. Dental Arches After the Set-Up

In order to make a proper analysis of the results obtained by comparing the digitally created set-up and the final model of the patient, the following measurements were made: the length of the dental arches; upper and lower intercanine distance; upper and lower intermolar distance. All the virtual measurement was made online on webceph.com (Seongamsi, South of Korea) and the conventional casts were measured using a digital caliper (fig. 3).

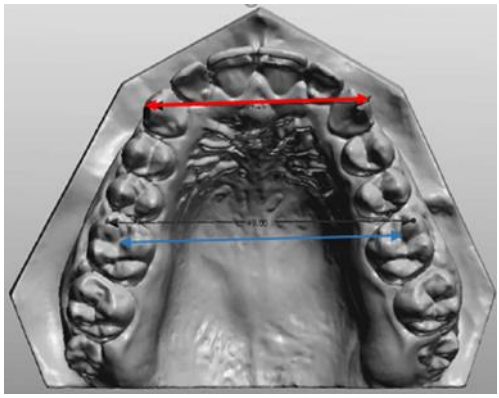

Fig. 3 Measurements on the Models

Student T-test and Wilcoxon, level of significance $p<0.05$ was used to statistically analyze the results. Also, ANOVA relevance test allowed the simultaneous evaluation of the three cases.

RESULTS

Forty patients were included in this study: 18 male and 22 female aged 11-43 years. The patients were distributed into groups according to the dental classes. By calculating the average values recorded as a result of the measurements performed and the standard deviation, obtained after the elimination of extreme outlier type values, the data were entered in first table to be able to be further compared descriptively and analytically from a statistical point of view.

TABLE I.
Mean and Standard Deviation

	Initial Model		Final Model		Set-up	
	Mean (mm)	SD (mm)	Mean (mm)	SD (mm)	Mean (mm)	SD (mm)
Upper Inter-Molar Distance	46,84	3.07	44.51	2.06	47.65	2.10
Lower Inter-Molar Distance	48.44	2.92	47.36	2.23	48.84	2.86
Upper Inter-Canine Distance	34.84	3.12	35.12	1.93	37.42	1.84
Lower Inter-Canine Distance	28.04	2.29	26.8	1.34	28.42	1.83
Upper Arch Length	118.07	9.24	111.14	1.00	113.97	6.25
Lower Arch Length	110.05	12.04	107.01	5.38	108.18	4.27

The statistical tests showed a significant difference for the comparison of the Lower Inter-Canine Distance (p=0.007) and Upper Arch Length Distance (p=0.02) values. The difference for the Lower Inter-Canine Distance was confirmed further in comparing all the 3 situations simultaneously (p=0.03).

DISCUSSION

The significant difference between the setup and the final model at the level of the length of the upper arch, through might be explained by an effect of "shortening of the dental arch". The oscillation between the mean values (2.83 mm) led to the emergence of significant differences by applying statistical tests, which could be explained by the fact that the degree of retrusion of the frontal group, as well as the molar mesialization after extraction was much higher than was previewed via the digital set-up. Another, more pronounced difference can be observed at the level of the lower intercanine distance. This variation poses problems from the point of view of maintaining the stability of the result obtained after orthodontic treatment for a long term.

A similar study was performed by Monica S. Barretoa *et al.*, (18,19) who made the same measurements in order to evaluate the differences obtained. Analyzing their results, a statistically significant difference is observed in the intercanine distance of the upper arch ($p<0.001$). Comparing the data described in their study with those obtained in ours, a similarity of the values was observed, the greatest variation being obtained at the level of the intercanine distance. From a clinical point of view, their research shows that especially in cases that require the extraction of premolars to obtain functional intermaxillary relations, the risk of relapse following orthodontic treatment is directly proportional to the changes in the intercanine distance. Therefore, it is extremely important to keep this value as close as possible to the initial one, thus minimizing the risk of relapse. (20,21)

Another more complex research made by Takuya Kihara *et al.* (22) analyzed the clinical data of 5 patients to demonstrate the importance of root position preview in the digital set-up. A significant difference was detected in the root distance between anterior and posterior teeth ($p < 0.05$). Takuya Kihara emphasizes through this study the importance of previewing the final result of orthodontic treatment from the perspective of the position and condi-

tion of the dental roots. He believes that this is one of the most common complications of orthodontic treatment, so special attention should be paid to this aspect (23).

Another study was carried out by Fabio Federici Canova *et al.* (24), which evaluates the predictability of the set-up of the same patient performed with four different programs, including the one used by us - Blue Sky Plan. It remains one of the most current at the moment, because it possesses a wide range of "tools" that make the work of the practitioner easier, facilitating the clinical applicability of the implemented changes (24, 25).

New technologies make orthodontic therapy more efficient and predictable. And the results of this study demonstrate that the use of digital set-ups is a reliable method of evaluating the treatment plan, as it provides a three-dimensional preview of the patient's occlusion at the end of the orthodontic treatment. This allows for greater trust and strengthens the doctor-patient relationship.

CONCLUSIONS

The comparison made in this study between the digital set-up and the patient's final model gives confidence in choosing the setup as a reliable tool for treatment planning.

Preserving the intercanine distance following orthodontic treatment is an important factor for relapse prevention.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

THE BENEFIT OF MOLECULAR MICROBIOLOGICAL ASSAYS IN THE OPTIMAL MONITORING OF PERIODONTAL DISEASE. A RETROSPECTIVE STUDY (Abstract): Periodontal disease is among the most frequent pathologies worldwide, with multiple consequences to the quality of daily patient life. **Aim:** To assess the prevalence and the DNA load of etiologic agents in selected patients with periodontal disease. **Materials and methods:** 55 saliva samples from periodontal disease patients were analyzed by multiplex Real Time PCR, using specific primers for: *Aggregatibacter actinomycetemcomitans, Porphyromonas gingivalis, Treponema denticola*. The positive sampled were further analysed for the evaluation the antibiotic susceptibility to Clindamycin, Metronidazole, Amoxicillin, Doxycycline, Ciprofloxacin, and Clarithromycin. **Results:** The most frequent bacteria detected were *Treponema denticola*, in samples from 47 patients (85.5%), followed by *Porphyromonas gingivalis*, in 43 patients (78.2%) and *Aggregatibacter actinomycetemcomitans*, in 5 patients (9.1%). Besides these 3 periodontal pathogens, one patient was positive for *Tannerella forsythia, Prevotella intermedia, Eubacterium nodatum and Capnocytophaga gingivalis.* **Conclusions:** The microbiologic diagnosis using sensitive molecular assay is compulsory for modern and optimal periodontal diseases assessment. **Keywords:** PERIODONTAL PATHOGEN, CLINICAL GUIDELINE, REAL-TIME PCR, DIAGNOSIS, TOOTH SURVIVAL.

Periodontal disease is the most frequent chronic noncommunicable human disease worldwide, with important implications in the daily life of diagnosed patients, as tooth loss and disability lead to lower quality-of-life, has been associated with diabetes, cardiovascular diseases and with increased medical expenditure. The global burden of severe periodontitis has been substantial and increasing over the past three decades. In 2019, there were registered 1.1 billion prevalent cases of severe periodonti-

tis globally (1).

Many groups of researchers elaborate guidelines, for optimization of disease prevention, detection, and efficient therapy. Periodontal specialists elaborated a UK version of the European Federation for Periodontology S3-level clinical practice guideline which include consensus-based clinical recommendations of direct relevance to the dental community in the UK and encompasses 62 clinical recommendations for the treatment of stage I-III periodontitis, based on a stepwise process mapped to the 2017 classification system (2).

The UK healthcare experience recognize the benefit of Metronidazole + Amoxicillin for periodontal infections, but at the same time, the authors mention the risk of side effects regarding antibiotics overuse. These can lead to an increase in antimicrobial resistance genes, dysbiosis, and impacts on the microbiome. Given the potential harm vs. benefit considerations on the use of antibiotics (stewardship issues), the evidence-based recommendation supports the use of locally administered sustained-release antibiotics as an adjunct to subgingival instrumentation in patients with periodontal disease (2).

A more recent guideline of The European Society of Endodontology was elaborated by Duncan HF *et al*., which have used a robust, rigorous, and transparent process including the analysis of relevant comparative research in 14 systematic reviews. The guideline describes a series of clinical recommendations the effectiveness of diagnosing apical periodontitis, to preserve teeth over a patient's lifetime, according to the best comparative evidence currently available (3).

The understanding of etiopathogenesis of periodontal diseases, motivated the European researchers to evaluate the benefit of systemic periodontal antibiotic therapy versus the use of antimicrobials to target bacteria in subgingival biofilms in the periodontal pocket. Even though systemic therapy seems to be efficient, the current recommendations are limited because of the very well-known emergence of antibiotic resistance. The authors named their review very suggestive: “Europe’s contribution to the evaluation of the use of systemic antimicrobials in the treatment of periodontitis” (4).

These guidelines motivated us to evaluate patients in our area and publish our findings in this study.

AIM: to assess the etiology of periodontal pathogens in a study group of Romanian periodontal disease patients, and to follow up the efficiency of antibiotic therapy.

MATERIALS AND METHODS

For the accurate determination of periodontal pathogens, in the period 12.03.2018 - 17.11.2022, we have tested 55 patients clinically diagnosed with periodontitis or peri-implantitis, using PET (periodontitis / peri-implantitis pathogens test). From each patient we collected samples of plaque from the periodontal pockets or affected implants of patients with the use of small paper tips. These samples of plaque are not sensitive to the effects of transportation, as we analyzed DNA, which is stable in such conditions. The first step of the PET assay used involved the DNA purification. A highly sensitive molecular biology technique, real-time PCR was used in the case of every individual sample, using specific primers for our tested etiologic agents. With this method, the genetic material (the DNA) of the bacteria which it contains was processed following the classical known steps of qRTPCR: DNA denaturation, primer annealing and extension. The purified DNA was tested by multiplex Real Time PCR for the next known etiologic agents of

periodontal disease: *Aggregatibacter actinomycetemcomitans, Porphyromonas gingivalis, Treponema denticola, Tannerella forsythia, Prevotella intermedia, Peptostreptococcus micros, Fusobacterium nucleatum, Eubacterium nodatum* and *Capnocytophaga gingivalis.* For positive samples, the antibiogram was performed for Clindamycin, Metronidazol, Amoxicillin, Doxycycline, Ciprofloxacin, and Clarithromycin, using a CFU (colonies forming units' assay) based assay. We analyzed our data with SPSS 20.0 software package, for descriptive statistics.

The institutional approval for the study was not applicable considering the retrospective design of the study.

RESULTS

The mean age of the study group was 35.15 years old (limits 13 - 79), 38 (67.9%) being female. Repartition of patients per age group and gender are reported in first table.

TABLE I.

Demographic data: age group - gender crosstabulation

		Gender		
		F	M	Total
Age_group		7	4	11
	11 - 20	2	0	2
	21 - 30	10	6	16
	31 - 40	10	4	14
	41 - 50	4	2	6
	51 - 60	3	1	4
	61 - 70	1	0	1
	71 - 80	1	0	1
Total		38	17	55

The Real Time PCR assay included a qualitative and quantitative assessment of the detected pathogens. The detected bacterial load varied between 10^1 - 10^9. The highest bacterial load was detected for *Porphyromonas gingivalis.* The ratio of the different pathogens was also determined. This approach is driven by the fact that some pathogens pose a risk only when present in large numbers or when they coexist with other pathogens, while others can lead to disease progression even when present only in small amounts.

Treponema denticola was detected in 47 patients (85.5%). The highest frequency was detected for the bacterial load of 10^4 in saliva: 20 (36.4%). *Porphyromonas gingivalis* was detected in 43 patients (78.2%). The highest frequency was detected for the bacterial load of 10^5 in saliva: 18 (32.7%). *Aggregatibacter actinomycetemcomitans* was detected in 5 patients (9.1%), each of them with different concentration. *Prevotella intermedia* was detected just in one patient (1.8%), with a load of 10^4. *Peptostreptococcus micros* and *Capnocytophaga gingivalis* were detected just in one patient, (1.8%), each with a concentration of 10^3. *Fusobacterium nucleatum* was not detected in any patients. *Tannerella forsythia, Prevotella intermedia, Eubacterium nodatum* and *Capnocytophaga gingivalis* were present just in one female patient, with a 10^4 bacterial load for the first two species, and 10^3 for the last two.

The highest prevalence for *Porphyromonas gingivalis* was detected for group age 31 - 40 (7/18, 38.9%), and the highest bacterial load (10^6) was detected in the 21 - 30 age group, 4/20, 20% (Figure 1). The highest prevalence for *Treponema denticola* was detected for group age 21 - 30 (19/20, 95%), and the highest bacterial load (10^6) was detected in the 21 - 30 age group, 1/20, 5% (Figure 2).

The prevalence for *Aggregatibacter actinomycetemcomitans* was equally detected for each age group (1, 29.1%), and the highest bacterial load was also in 31 - 40 age group: 10^6, 1/14 (7.1%). We found no significant statistical association (tabs. II, III).

Fig. 3. Example of a significant increase in the number of bacteria belonging to the red and orange complexes.

We found no statistical difference between age group and the most frequent bacteria identified in our samples.

For the patient with the above qPCR results (fig. 3), the suggested therapy according with antibiogram results, was Clindamycin, 2 x 600 mg/day, 7 days in association with Metronidazole 3 x 400 mg/day, 7 days.

DISCUSSION

In this study we have evaluated the prevalence of periodontal pathogens in 55 patients diagnosed with periodontal disease, using Real Time PCR. Our data are in accordance with those of other groups of researchers who used the same molecular assay.

The etiology of periodontal diseases has been evaluated by many researchers worldwide. Ergün E *et al.*, used Real Time PCR assay to evaluate the microbial content of periodontal abscesses, using 16S rRNA Universal primers. They detected *Porphyromonas gingivalis, Prevotella intermedia* and *Fusobacterium nucleatum* in all 30 tested samples. Other bacterial species were detected with lower frequency: *Porphyromonas endodontalis, Tannerella forsythia, Actinomyces naeslundii* (5). Reddahi S *et al.*, from Morocco investigated periodontal pathogens in saliva from 53 patients with qPCR and they identified a significant difference in *P. gingivalis* and *A. actinomycetemcomitans JP2* clones in the saliva of periodontitis patient compared to the control group. The researchers consider testing of

etiologic agents of periodontal disease a good potential as diagnostic markers for periodontal disease (6). A more comprehensive study was realized by Chigasaki O. *et al*, in Japan, which tested almost 1000 periodontal disease patients with Real Time PCR. The authors found that *P. gingivalis* was strongly associated with an increase in the rate of sites of 4 mm or greater probing pocket depth, bleeding on probing, and 1.5 mm or more of bone loss on dental radiographs sites. For this study group, the amount of *P. gingivalis* was strongly associated with the severity of periodontal disease. Other bacteria from red-complex as *T. denticola* and/or T. *forsythia* showed heightened progression of periodontitis (7).

Eick S. *et al.*, tested by RT-PCR Swiss adolescent subjects, and detected 10 % to be positive for *P. gingivalis*, 23% for *A. actinomycetemcomitans* and *T. forsythia*, and 47.5% for *T. denticola* (8).

Wang P *et al.*, evaluated through the same assay, qPCR, periodontal pathogens in 25 patients with chronic periodontitis. Our study shows comparable results to theirs, *Treponema denticola* having the highest prevalence. The authors identified that human beta-defensins may play an important role by limiting an increase of bacterial load at the initial stage of periodontitis (9).

In a recent study from 2023, Castillo Y. *et al*. aimed to standardize a qPCR assay for periodontal pathogens, in 55 subgingival biofilm clinical samples, from different stages of periodontitis. The results obtained using qPCR were compared with next-generation sequencing (NGS) results, and the researchers considered that this qPCR test was standardized with efficiencies between 90% and 100%. *Eubacterium saphenum, Eubacterium brachy, Desulfobulbus oralis,* and *Filifactor alocis* which are periodontal pathogens difficult to be cultivated, could be easily detected by this standardized qPCR assay (10).

Limitations of the study: considering the sample population of the current study, further research is necessary to validate our findings. Nowadays, in the era of new technology, there are other modern molecular assays which are used for the detection of periodontal pathogens, understanding new pathogenic mechanisms, finding therapeutic target genes (11) or testing biomarkers in periodontal disease associated conditions, such as diabetes (12). For example, a research team from Greece combined Real Time PCR with matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-ToF MS) and they detected *Aspergillus* and *C. albicans* in 60 cases of apical periodontitis (13). Rams TE *et al*., from the USA, used MALDI TOF for subgingival isolates from 38 adults with chronic periodontitis and all *P. gingivalis* subgingival isolates were confirmed as *P. gingivalis* with MALDI-TOF. The authors considered MALDI-TOF as fast phenotypic identification of cultivable *P. gingivalis* in human subgingival biofilm specimens (14). Jeong J *et al*., from Korea used next-generation sequencing (NGS)-based 16S metagenome profiling data to confirm the presence of *Porphyromonas gingivalis* in periodontal patients (15).

CONCLUSIONS

Molecular methods as Real Time PCR are compulsory in optimal management of periodontal diseases since many of the etiological agents are non-cultivable or require accurate quantitative assessment to understand their clinical significance. With sensitive, specific, and clinically validated detection assays and targeted therapy, evo-

lution to more severe consequences could be stopped.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest and they received no funding

PERCEIVED STRESS AND COPING MECHANISMS AS DETERMINING FACTORS OF THE QUALITY OF LIFE FOR CAREGIVERS OF PATIENTS WITH CHRONIC DISEASES IN ROMANIA (Abstract): **The objective of this study** was to identify how the impact of perceived stress and the coping mechanisms used by caregivers of patients with chronic diseases in Romania determine their quality of life (QoL). **Materials and methods**: 69 caregivers of patients with chronic diseases participated in the study. The data resulted from the completion by the caregivers of the Perceived Stress Questionnaire (PSQ), the COPE scale, and the World Health Organization Quality-of-Life Scale (WHOQOL-BREF), along with a series of questions related to demographic data, such as gender, age, the environment of origin, the educational level, the civil status, the degree of kinship with the patient, the time since finding out the diagnosis, and the patient's diagnosis. **Results**: The findings indicate that there was no significant correlation between perceived stress and QoL. High scores on planning were associated with high scores on QoL, and high scores on restraint from action were associated with low scores on QoL. As for carers, spouses had higher QoL scores compared to the children of the patient with a chronic disease, but also in comparison with the caregivers who were the mother or the father. Caregivers with high scores for pessimism regarding the diagnosis obtained higher QoL scores compared to caregivers who were hopeless. Within the predictive model composed of perceived stress and coping styles, the predictors were restraint from action (β = .416), denial (β = .397), mental passivity (β = .155), and recourse to alcohol-drugs (β = -.238), all of which were significant predictors, and the strongest predictor was restraint from action (β = .416). **Conclusions**: Caring for a patient with a chronic diagnosis is often a powerful experience for caregivers. The additional tasks taken on with this role, the changes in the previously known rhythm of personal life, and the intensity of the felt stress left important traces in the mental and physical state of the caregivers. The way they perceive stress and the coping mechanisms they use can positively influence their QoL, adjusting their intensity of the new role. **Keywords:** COPING MECHANISMS, QUALITY OF LIFE, CAREGIVERS, CHRONIC DISEASES.

INTRODUCTION

Caring for a patient with a chronic disease can be an overwhelming experience for caregivers, involving personal reframing in the context of patient care. Chronic diseases are characterized by a long-term evolution with persistent or recurrent symptoms and require complex management in order to maintain health and improve the patients' QoL. In the category of chronic diseases there is a wide range of ailments (e.g., neurological, oncological, cardiac, and mental) for which a personalized and integrated approach is necessary. Chronic disabling diseases are one of the world's leading causes of disability, affecting millions of people (1). These diagnoses cause an important limitation of both movement and general functioning of the patients (2). Studies have identified a significant association between patients with chronic diseases and the decrease in the QoL of their caregivers. Factors such as the nature and severity of the diagnosis, as well as the treatments and recuperative therapies followed by the degree of disability developed, considerably affect the QoL. In the case of diseases that require aggressive treatments (e.g., oncological diseases), the physical and mental functionality of the patients is significantly influenced (2). For patients with neurological conditions such as cerebral palsy (CP), stroke, Parkinson's disease, Alzheimer's, dementia, multiple sclerosis, etc., the limitation of cognitive status and the degradation of motor function lead to important challenges in daily activities, limiting independence, and the activities are often impossible to carry out without the help of another person.

Quality of life (QoL) is a "subjective assessment of individual well-being, which may include aspects such as physical and mental health, family and social satisfaction, personal achievements and the subjective level of happiness and satisfaction" (3). QoL is a multidimensional construct that reflects the level of physical, psychological, and social functioning of the person. QoL is influenced by factors such as health status, and social or economic conditions (4). Each person perceives and evaluates the QoL through their own standards and criteria, and these vary due to various factors, such as age, health status, or culture. The aspects that build the QoL are either objective (e.g., living standards, health status) or subjective (e.g., the individual's perception of his own life) (5). QoL is a broad concept, resulting from the interaction between the subjective and objective perspectives and influencing the individual's perception of his own life (6).

The caregivers the person who provides support and assistance to a family member or a person diagnosed with an illness, being responsible for the patient's care and well-being, regardless of the type of illness or its severity. Being the main caregiver of a sick person can be compared to having a full-time job (7). Caregivers provide physical care, social support, and emotional support, coordinate medical care, and administer the financial and administrative aspects associated with the diagnosis (8, 9, 10).

Caregivers contribute to the sustainability of health systems by delaying or preventing institutionalized care (11). Carers' responsibilities subsequent to the patient's care can often lead to personal sacrifices, significantly limiting their QoL on multiple levels, including their professional life, interpersonal relationships, or emotional state (12, 13). The long-term impact of patient care is felt by primary caregivers both physically and emotionally. Due to the demanding and difficult role they undertake, which requires important personal

sacrifices, they present a high degree of risk for mental health problems, making them more susceptible to developing depression or anxiety (14, 15). Taking on the multifaceted care of a patient with a chronic illness exposes them to elevated levels of stress, anxiety, and physical exhaustion (13, 16). The uncertainty about the diagnosis's prognosis and the constant, sustained effort to meet the patient's complex needs further intensify this state (17).

The degree to which caregivers believe that their own or external resources are insufficient to meet demands, real or imagined, determines the level of stress experienced by them. The specialized literature has shown that the caregivers of patients with chronic diseases face high levels of perceived stress. Increased levels of stress can lead to the emergence of dysfunctional emotional reactions, which can be exacerbated by feelings such as powerlessness or lack of control over the situation in which they find themselves (18). The stress that caregivers experience as a result of their ongoing effort to provide for the patient's requirements is frequently frustrating and overwhelming, to the point of physical and mental exhaustion (19, 20).

Thus, physical as well as emotional exhaustion can be the direct consequence of the high levels of persistent stress associated with caring for patients with chronic diseases, affecting the ability of caregivers to carry out the necessary daily responsibilities.

Regarding coping mechanisms, research has highlighted the strategies used by caregivers of patients with chronic diseases to cope with the stress associated with diagnoses. The normal or pathological reaction to stress depends on the coping capacities of each individual and the way in which they adapt to the stressful context (21).

Personal experiences, the individual's social or cultural context, and the resources available all influence the development of coping mechanisms as a personal response to stressful or challenging situations.

Coping mechanisms represent an important base of tools for the caregivers of patients with chronic diseases, with a significant impact on their QoL (22). Thus, the present study aims to analyze the QoL of the carers of patients with chronic diseases, through the lens of coping mechanisms and the stress perceived by them.

MATERIALS AND METHODS

Participants and procedure

The study participants were people who were patients with chronic diseases (e.g., Alzheimer's, cancer, stroke, dementia, multiple sclerosis, etc.).

The data collection procedure was carried out using the Google Forms research platform. After uploading the questionnaire, the link generated by the platform was shared among the caregivers of chronic disease patients. The participants were informed in advance about the conditions of participation (voluntary participation; withdrawal from the study at any time without any consequences; anonymity and confidentiality of answers) and the general objective of the study.

Instruments

Socio-demographic data

A series of questions were related to demographic data, such as gender, age, background, educational level, civil status, degree of kinship with the patient, time since finding out the diagnosis, and the patient's diagnosis.

Psychological data

- **Coping strategies.** To measure this variable, we used the COPE Questionnaire (Carver *et al*., 1989) which consists of 53 items, rated on a 4-point Likert scale, from 1

(I usually don't do this) to 4 (I often do this). Additionally, the questionnaire consists of 14 dimensions representing all coping styles: active coping ("I engage in additional activities that can contribute to solving the problem."), planning ("I try to formulate a strategy about what I have to do."), elimination of recurring activities ("I put aside other activities to focus on the problem."), withholding from action ("I force myself to wait for the right moment to react."), seeking social-instrumental support ("I ask people who have been through similar situations what they did in that situation."), seeking social-emotional support ("I tell someone how I feel."), positive reinterpretation ("I look for something good in what happens to me."), acceptance "I'm learning to live with my problem."), denial ("I refuse to believe what happened."), emotional discharge ("I'm in a bad mood and I'm externalizing my emotions."), religious orientation ("I'm looking for God's help."), mental passivity ("I engage in work or other activities to take my mind off the problem."), behavioral passivity ("I give up trying to get what I want."), resorting to alcohol-medication ("I drink alcohol or take medication to think less about the problem."). The Alpha Cronach coefficients of each dimension were in the range of .600 - .900, which indicates a satisfactory level of internal consistency of the items. The score was made on each dimension, and a high score indicates a high level of the respective coping style.

- **Perceived stress.** To measure this variable, we used the Perceived Stress Questionnaire (Levenstein *et al.*, 1993). The instrument consists of 30 items ("I feel rested"; "I feel that I cannot manage to achieve my personal goals"; "I do many things because I have to do them and not because I like them.") rated on a 4-point Likert scale from 1 (almost never) to 4 (almost always). Cronbach's Alpha coefficient was .856, which means that there was a good level of internal consistency. The total score was made summative, and a high score indicates a high level of perceived stress.

- **Quality of life.** To measure the variable "quality of life", we used the **WHOQOL** questionnaire developed by the World Health Organization (1996). The instrument consists of 26 items covering several aspects related to life in general, such as: subjective well-being, sleep, workplace, personal home, public health services, financial situation, etc. In the present study, only 8 items were used: ("How would you rate your quality of life?"; "Have you got enough money to meet your needs?"; "Have you got enough money to meet the patient's needs?"; "How satisfied are you with the support you get from your friends?"; "How satisfied are you with the conditions of your living place?"; "How satisfied are you with your access to health services?"; "How satisfied are you with your transport?"; "In the last 2 weeks, how often have you had negative feelings such as dark mood, despair, anxiety, depression?"). Items were rated on a 5-point Likert scale from 1 (not at all) to 5 (very much). Cronbach's Alpha coefficient was .767, which indicates a satisfactory level of item consistency. The total score was made summative, and a high score indicates a high level of QoL.

Statistical analysis

The statistical analyses were performed using IBM Statistical Package for Social Sciences (SPSS) for Windows, version 24 (SPSS Inc., Chicago, IL, USA). Results for descriptive statistics were expressed as means and standard deviations (SD).

To test the hypotheses of the study, de-

scriptive statistics including average, standard deviation, minimum score, maximum score, and indices of normality of distribution Skewness and Kurtosis were performed. Given that the Skewness and Kurtosis indices ranged between -1 and +1 for Skewness and -3 and +3 for Kurtosis, we can conclude that the data distribution is normal.

Ethical approval

The study was conducted in accordance with the Declaration of Helsinki, and the protocol was approved by the Ethical Committee of Faculty of Psychology and Educational Sciences, "Alexandru Ioan Cuza" University Iasi, Romania No. 511/2024.

RESULTS

Socio-demographic data

In total, there were 69 participants aged between 25 and over 65, the majority being female participants (10 participants were male and 59 participants were female).

Most participants reported being married (N = 60), from an urban environment (N = 51), and of Orthodox religion (N = 65).

Regarding the degree of relationship to the patient, 35 participants reported being the patient's spouse, 22 participants reported being the patient's mother or father, 11 participants reported being the patient's child, and only one participant reported being the patient's cousin.

Psychological data

The results of the psychological instruments used for the present research (experienced stress, quality of life and, coping mechanisms) among caregivers of chronic disease patients are presented in first table.

TABLE I.

Descriptive statistics (N = 69)

	M	SD	Min	Max	Skewness	Kurtosis
Perceived stress	79.53	11.63	59	100	-.06	-1.26
Active coping	13.79	1.95	8	16	-.68	-.06
Planning	13.98	1.95	8	16	-.85	.17
Elimination of competing activities	12.82	1.96	7	16	-.54	.16
Restraint from action	11.60	1.94	6	16	-.22	.10
Search for social-instrumental support	12.11	2.63	4	16	-.11	1.63
Seeking social-emotional support	8.78	3.06	4	16	.50	-.47
Positive reinterpretation	11.04	3.03	5	16	.05	-1.05
Acceptance	11.31	3.21	4	16	-.27	-.64

Resorting to alcohol-drugs	1.44	.88	1	4	.87	.31
Life quality	23.27	3.91	14	29	-.49	-.53

Hypotheses

H1. There was a significant and negative correlation between perceived stress and QoL.

H2. There was a significant correlation between coping styles and QoL.

H2.1. There was a significant and positive correlation between active coping and QoL.

H2.2. There was a significant and positive correlation between planning and QoL.

H2.3. There was a significant and negative correlation between elimination of recurrent activities and QoL.

H2.4. There was a significant and negative correlation between restraint and QoL.

H2.5. There was a significant and positive correlation between seeking social-instrumental support and QoL.

H2.6. There was a significant and positive correlation between seeking social-emotional support and QoL.

H2.7. There was a significant and positive correlation between positive reinterpretation and QoL.

H2.8. There was a significant and positive correlation between acceptance and QoL.

H2.9. There was a significant and negative correlation between denial and QoL.

H2.10. There was a significant and positive correlation between emotional discharge and QoL.

H2.11. There was a significant and positive correlation between religious orientation and QoL.

H2.12. There was a significant and negative correlation between mental passivity and QoL.

H2.13. There was a significant and negative correlation between behavioral passivity and QoL.

H2.14. There was a significant and negative correlation between alcohol-medication use and QoL.

H3. There were significant differences in QoL between spouse, child, and mother or father who were caregivers for the patient with a chronic illness.

H4. There were significant differences in QoL since the diagnosis was made (less than 6 months, 6 months to 1 year, 1 year to 3 years, and more than 3 years).

H5. There were significant differences in QoL depending on how caregivers relate to the patient's diagnosis (worried, pessimistic, hopeless, confident, and resigned).

H6. Perceived stress and coping styles significantly predicted QoL.

Hypothesis testing

H1. There was a significant and negative correlation between perceived stress and QoL.

The results obtained indicated that there was no significant correlation between perceived stress and QoL ($r = .011$, $p = .929 > .05$).

H2. There was a significant correlation between coping styles and QoL.

To test hypothesis 2, we used the Pearson correlation.

H2.1. There was a significant and positive correlation between active coping and QoL. The obtained results indicated that there was no significant correlation between active coping and QoL ($r = .214$, $p = .078 > .05$).

H2.2. There was a significant and positive correlation between planning and QoL. Results obtained indicated that there was a significant and positive correlation between planning and QoL ($r = .376$, $p = .001 < .01$), in the sense that high scores on planning were associated with high scores on QoL.

H2.3. There was a significant and negative correlation between eliminating competing activities and QoL. The results generated by the data analysis indicated that there was no significant correlation between the elimination of competing activities and QoL ($r = .012$, $p = .922 > .05$).

H2.4. There was a significant and negative correlation between restraint and QoL. Statistical analysis of the data indicated that there was a significant and negative correlation between restraint and QoL ($r = -.304$, $p = .011 < .05$), meaning that high restraint scores were associated with low QoL scores.

H2.5. There was a significant and positive correlation between seeking social-instrumental support and QoL. The obtained results showed that there was no significant correlation between the search for social-instrumental support and the QoL ($r = .145$, $p = .235 > .05$

H2.6. There was a significant and positive correlation between seeking social-emotional support and QoL. The obtained data demonstrated that there was no significant correlation between the search for social-emotional support and the QoL ($r = -.031$, $p = .802 > .05$).

H2.7. There was a significant and positive correlation between positive reinterpretation and QoL. Research results indicated that there was no significant correlation between positive reinterpretation and QoL ($r = -.025$, $p = .841 > .05$).

H2.8. There was a significant and positive correlation between acceptance and QoL. Results obtained showed that there was a significant and positive correlation between acceptance and QoL ($r = .280$, $p = .020 < .05$), in the sense that high scores on acceptance were associated with high scores on QoL.

H2.9. There was a significant and negative correlation between denial and QoL. Data analysis proved that there was no significant correlation between denial and QoL ($r = -.073$, $p = .549 > .05$).

H2.10. There was a significant and positive correlation between emotional discharge and QoL. The obtained results showed that there was a significant and positive correlation between emotional discharge and QoL ($r = .246$, $p = .042 < .05$), in the sense that high scores on emotional discharge were associated with high scores on QoL.

H2.11. There was a significant and positive correlation between religious orientation and QoL. The obtained results demonstrated that there was no significant correlation between religious orientation and QoL ($r = -.073$, $p = .550 > .05$).

H2.12. There was a significant and negative correlation between mental passivity and QoL. The obtained results indicated that there was no significant correlation between mental passivity and QoL ($r = -.025$, $p = .839 > .05$).

H2.13. There was a significant and negative correlation between behavioral passivity and QoL. We identified that there was a significant and negative correlation between behavioral passivity and QoL ($r = -.343$, $p = .000 < .01$), in the sense that high scores on behavioral passivity were associated with low scores on QoL.

H2.14. There was a significant and negative correlation between alcohol-medication use and QoL. The analysis of the obtained data proved that there was a significant and negative correlation between the recourse to alcohol-medicines and the QoL ($r = -.330$, $p = .006 < .01$), in the sense that high scores on the recourse to alcohol-medicines were associated with low QoL scores. The results obtained are presented in second table.

H3. There were significant differences in QoL between the spouse, child and mother or father who were caregivers for the patient with a chronic illness.

To test hypothesis 3, we used One-Way ANOVA. The results indicated that there were significant differences between caregivers who were the spouse (M = 24.74, SD = 3.12) and caregivers who were the child (M = 21.36, SD = 4.29) of the patient with a chronic illness ($F(2,68) = 5.807$, $p = .005 < .05$, Mdif = 3.37, $p = .029 < .05$), in terms of QoL, meaning that spouses had higher QoL scores compared to caregivers who were the child of the patient with a chronic disease.

Additionally, there were significant differences between the caregivers who were the husband or wife (M = 24.74, SD = 3.12), and the caregivers who were the mother or father (M = 21.95, SD = 4.07) of the patient with a chronic illness (F(2,68) = 5,807, p = .005 < .05, Mdif = 2,78, p = .018< .05), in terms of QoL, in the sense that spouses had higher QoL scores, compared to caregivers who were the mother or father of the patient with a chronic disease.

TABLE III.

Differences between spouses, children and mothers or fathers in terms of QoL

Relationship type		Mdif	SD	p
Husband / wife	Child	3.37	1.26	.029
	Mother/father	2.78	.98	.018
Child	Husband/wife	-3.37	1.26	.029
	Mother/father	-.59	1.34	1.000
Mother / father	Husband/wife	-2.78	.98	.018
	Child	.59	1.34	1.000

The obtained results indicated that there were no significant differences between the caregivers who were the mother or father (M = 21.95, SD = 4.07) and the caregivers who were the child (M = 21.36, SD = 4.29) of the patient with a chronic disease (F(2,68) = 5.807, p = .005 < .05, Mdif = -.592, p = 1.000 > .05).

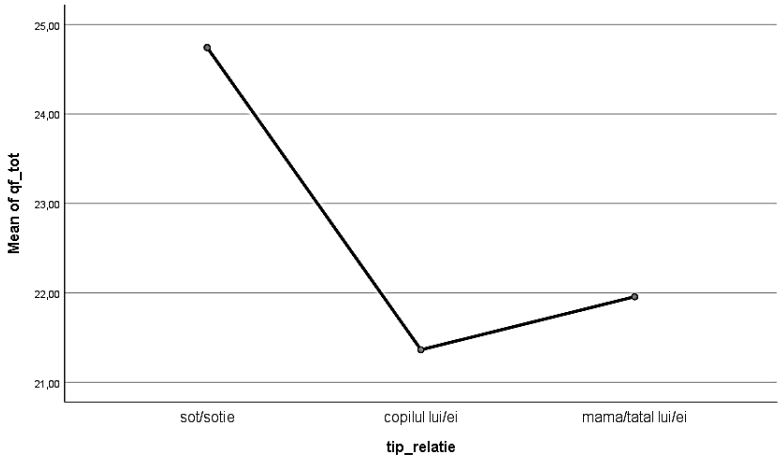

Fig. 1. Relationship type

H4. There had been significant differences in QoL since the time of learning the diagnosis (less than 6 months, 6 months to 1 year, 1 to 3 years, and more than 3 years).

The obtained results indicated that there were no significant differences in the QoL of caregivers of patients with chronic diseases, depending on the time since learning the diagnosis (F(3, 68) = 2.77, p = .049).

TABLE IV.

Differences in the level of QoL according to the time since finding out the diagnosis

Diagnosis time		Mdif	SD	P
less than 6 months	6 months - 1 year	1.71	1.55	1.000
	1-3 years	3.25	1.35	.113

	6 months - 1 year	-.96	1.51	1.000
	1-3 years	.57	1.30	1.000

H5. There were significant differences in QoL depending on how caregivers related to the patient's diagnosis (worried, pessimistic, hopeless, confident, and resigned).

The obtained results indicated that there were significant differences between the caregivers who were worried (M = 24.08, SD = 3.06) and the caregivers who were hopeless (M = 18.14, SD = 2.19) in terms of QoL ($F(4, 68) = 4.24$, $p = .004 < .05$, Mdif = 5.94, $p = .003 < .05$), meaning that caregivers who were worried had higher QoL scores compared to caregivers who were hopeless.

TABLE V.

Differences in the level of QoL depending on how caregivers relate to the diagnosis of the patient with a chronic disease

Relating to diagnosis		Mdif	SD	p
Concern	Pessimism	-.66	1.47	1.000
	Hopeless	5.94*	1.54	.003
	Confident	.71	1.11	1.000
	Resignation	.50	1.27	1.000
Pessimism	Concern	.66	1.47	1.000
	Hopeless	6.60*	1.85	.007
	Confident	1.38	1.51	1.000
	Resignation	1.16	1.63	1.000
Hopeless	Concern	-5.94*	1.54	.003
	Pessimism	-6.60*	1.85	.007
	Hopeless	-5.22*	1.58	.016
	Resignation	-5.44*	1.70	.022
Confident	Concern	-.71	1.11	1.000
	Pessimism	-1.38	1.51	1.000
	Hopeless	5.22*	1.58	.016
	Resignation	-.21	1.32	1.000
Resignation	Concern	-.50	1.27	1.000
	Pessimism	-1.16	1.63	1.000
	Hopeless	5.44*	1.70	.022
	Confident	.21	1.32	1.000

Significant differences were found between caregivers who were pessimistic about the patient's diagnosis (M = 24.75, SD = 3.37) and caregivers who were hopeless (M = 18.14, SD = 2.19) regarding QoL (F(4 , 68) = 4.24, p = .004 < .05, Mdif = 6.60, p = .007 < .05), meaning that caregivers who were pessimistic about the patient's diagnosis had higher QoL scores compared to caregivers who were hopeless.

The results obtained indicated that there were significant differences between caregivers who were hopeless (M = 18.14, SD = 2.19) and caregivers who were confident (M = 23.36, SD = 3.80) in terms of QoL (F(4, 68) = 4.24, p = .004 < .05, Mdif = -5.22, p = .016 < .05), meaning that caregivers who were confident had higher QoL scores compared to caregivers who were hopeless.

Statistical analysis of the data indicates significant differences between caregivers who were resigned to the diagnosis of the patient with a chronic disease (M = 23.58, SD = 3.89) and caregivers who were hopeless (M = 18.14, SD = 2.19) in terms of QoL (F(4, 68) = 4.24, p = .004 < .05, Mdif = 5.44, p = .022 < .05), meaning that caregivers who were resigned had higher QoL scores compared to caregivers who were without hope.

H6. Perceived stress and coping styles significantly predict QoL

The obtained results indicated that the predictive model made up of perceived stress and coping styles (coping, planning, elimination of recurring activities, restraint from action, search for social-instrumental support, search for social-emotional support, positive reinterpretation, acceptance, denial, emotional discharge, orientation towards religion, mental passivity, behavioral passivity, and recourse to alcohol-drugs) was a significant predictive model (F(15, 68) = 4.12, p = .000 < .05) that explains 53.8% of the variance of the dependent variable - the QoL of patients with a chronic disease. The predictors restraint from action (β = .416), denial (β = .397), mental passivity (β = .155), and recourse to alcohol-drugs (β = -.238) were significant predictors. The strongest predictor was restraint from action (β = .416).

DISCUSSION

The present study analyzed the relationship between perceived stress and coping strategies as determining factors of the QoL of caregivers of people with chronic diseases. The obtained results indicate a significant correlation between the stresses perceived by the patients' caregivers and their QoL in the sense that stress was able to negatively influence the QoL and was felt multidimensional. Perceived stress changed the level of personal functioning, both in terms of mental and physical health, in interpersonal relationships, in the financial or professional sphere, leading to a decrease in the QoL and the establishment of a general dysfunctional state.

Regarding the link between coping styles and QoL, the analysis of the 14 coping styles that follow the COPE scale reveals a significant and positive correlation between active coping and QoL, in the sense that active coping targeted concrete actions, with the aim of removing the stressor and its effects. As a conscious action, this coping style contributed to the QoL of caregivers of patients with chronic diseases, by constantly adjusting to stress factors (23, 24, 25). A significant and positive correlation also resulted from planning as a coping strategy and QoL. Thus, the active orientation towards identifying some modes of action was associated with a high degree of QoL of the carers.

Analyzing the data regarding the elimination of competing activities, the results showed that there was no significant correlation between this coping strategy and QoL. Therefore, the QoL was unaffected by avoiding distraction from stressful situations and focusing on solving the problem. A strong and unfavorable relationship was found between QoL and action restriction. This was a kind of active coping in that it involved focusing on the stressor but also acting passively until conditions permitted it (26).

The results indicate that there was no significant correlation between instrumental social support seeking and QoL or social support seeking.

Thus, the tendency to request information from those around or advice to improve the degree of stress did not change the QoL of the caregivers, although existing studies analyzing this correlation resulted in an increased QoL as a result of social support (27). The results of our study showed that the need for moral support or understanding from the social or family environment to reduce stress did not influence the QoL. Regarding the tendency to look on the positive side even in an undesirable situation as a form of stressor perception, there was no significant correlation between positive reinterpretation and QoL, while there was a significant and positive correlation between acceptance and QoL. Thus, an approach based on accepting reality and being aware of the present period increases the QoL (28, 29). At the same time, the results showed that there was no significant correlation between denial and QoL. As a coping mechanism, denial refers to positioning in the refusal to acknowledge that the new reality means changing the course of life as it was before the installation of the stress factor. The obtained results indicated that there was a significant and positive correlation between emotional discharge and QoL. Thus, expressing emotions reduces the level of distress, which contributes to the QoL (24). In the coping strategy regarding religious orientation as a form of situational reinterpretation, there was no significant correla-

tion between religious orientation and QoL. Although our result is in contrast with the existing studies, a possible explanation may reside in the lack of such research on the Romanian population, the existing studies being carried out on other populations (30, 31, 32). Similarly, analyzing the results regarding withdrawal in other activities, as a technique to avoid focusing on problems, there was no significant correlation between mental passivity and QoL (33). A significant and negative correlation resulted between behavioral passivity and QoL. Reducing effort or giving up action in favor of achieving the goal was associated with low QoL scores. A significant and negative correlation was identified between alcohol-medication use and QoL. Thus, the use of alcohol-medicines by patients' caregivers to alleviate negative states was associated with low QoL scores (34, 35, 36). It was also identified that planning as a coping strategy as well as emotional discharge correlates significantly and positively with a high QoL, while restraint from action correlates significantly negatively with QoL.

Marital or family status was also important. Regarding the QoL between the spouse, child, and mother or father caregivers of the patient with a chronic disease, the results indicate that there were significant differences between the spouse caregivers and caregivers who were the child of the chronic disease patient regarding life quality. Thus, the caregivers who were the husband or the wife had higher scores on the QoL compared to the caregivers who held another degree of kinship. A possible explanation is the emotional connection and the commitment of marital status, which can lead to a greater understanding and empathy between the partners of the couple. Studies on couple relationships showed a high adaptability to life's changes and challenges compared to people with other degrees of kinship (37, 38, 39). Additionally, the family caregivers who were the husband or wife had higher QoL scores compared to the family caregivers who were the mother or father of the patient with a chronic disease, but there were no significant differences between the family caregivers who were the mother or father and the family caregivers who were the child of the patient with a chronic disease (40). Thus, for the children who assumed the role of the main relative of the patient with a chronic disease, the QoL had a low level compared to the people who were the husband or wife of the patient. Young people who found themselves in this role presented a lower level of life compared to older caregivers (41, 42). At the same time, parents who were the main caregivers had a lower standard of living compared to the patient's husband or wife (43).

Regarding the QoL of caregivers of patients with chronic diseases depending on the time since learning the diagnosis, there were no significant differences. A possible explanation could be the adjustment of the caregivers to the new role and subsequent responsibilities and the development of resilience. By adjusting the strategies for managing the situation over time, once the shock associated with the diagnosis subsides, the family caregivers developed the inner resources and new mechanisms that support them in a good management of the situation, which can positively influence the QoL.

The results from the differences in dealing with the situation - how the caregivers deal with the patient's diagnosis (worried, pessimistic, hopeless, confident and re-

signed) showed that there were significant differences between anxious and hopeless caregivers in terms of QoL, in that anxious caregivers score higher on QoL compared to hopeless caregivers. A possible explanation could be that caregivers who were concerned proactively seek coping mechanisms, whereas those who were hopeless regress to a state of withholding action.

Likewise, caregivers who were pessimistic about the patient's diagnosis had higher QoL scores compared to caregivers who were hopeless. Finally, the results showed that caregivers who were resigned to the patient's diagnosis of a chronic illness had higher QoL scores compared to caregivers who were hopeless. The obtained results are in congruence with those identified in the specialized literature. Resignation is reflected in the change of one's own perspective and the assumption of adaptation to the new reality, while the lack of hope was felt as the despair and responsibility resulting from the new responsibilities, which significantly changed the level of the QoL of the caregivers (44). Research results on perceived stress and coping styles as predictors of QoL demonstrated that the predictive model composed of perceived stress and coping styles (coping, planning, elimination of recurring activities, restraint from action, seeking social-instrumental support, seeking social support -emotional, positive reinterpretation, acceptance, denial, emotional discharge, orientation towards religion, mental passivity, behavioral passivity, and recourse to alcohol-drugs) is a significant predictive model and explains 53.8% of the variance of the dependent variable - the QoL of caregivers patients with a chronic disease. Predictors such as withholding from action, denial, mental passivity and resorting to alcohol-drugs were identified as significant predictors. The strongest predictor was restraint from action. Restraint from action as a coping mechanism is correlated with a low QoL as proactive coping strategies can minimize potential stressors in the future (45).

Strengths and limitations of the study. The importance of the present study lies in its uniqueness. No study has investigated the link between perceived stress and coping mechanisms as predictors of the QoL of caregivers of patients with chronic diseases in Romania. As limitations, we can mention a larger number of participants that could provide generalized results for the topic addressed.

CONCLUSIONS

The experience of caring for a patient with a chronic diagnosis is often a powerful one for caregivers. The additional tasks taken on with this role, the changes in the previously known rhythm of life, and the intensity of the stress felt leave important traces in the mental and physical state of the carers. Through active coping, concrete actions with a role in reducing the stressor and constant adjustment, a higher degree of the QoL of the caregivers can be felt. By knowing the coping mechanisms suitable for the life context and by identifying the appropriate ways for the individual to act, the caregivers can go through the stage of patient care more easily and with a more positive positioning.

In addition to planning as proactive action, emotional release plays another important role in QoL, while behavioral passivity such as refraining from action or resorting to alcohol-drugs decreases perceived satisfaction.

In comparison to the carers who are the

mother and father of the patient and their child, the experience of the husband or wife of the patient with a chronic disease may be assimilated with a lesser intensity due to the nature and complexity of the relationship, but as an individual perception, the experience is lived in a way unique.

Regarding the QoL of the caregivers of patients with chronic diseases, depending on the time since learning the diagnosis, no significant changes were reflected in the QoL of the caregivers. As situational positioning and reporting, caregivers who were anxious, resigned, or pessimistic reported a more satisfying QoL, compared to hopeless caregivers.

DISTRIBUTION OF ASTROCYTIC TUMORS AND BRAIN METASTASES BY ANATOMICAL LOCATION: A STUDY CONDUCTED ON 91 PATIENTS (Abstract): This retrospective study examines the distribution of astrocytic tumors and brain metastases based on anatomical location. **Materials and methods:** the study included a cohort of 91 patients treated at "Prof. Dr. N. Oblu" Emergency Clinical Hospital in Iasi, Romania, between 2011 and 2023. The study focuses on tumors localized in the frontal, parietal, and temporal lobes, with a particular emphasis on the association between these tumors and pre-diagnosis psychiatric symptoms. **Results:** Data were collected from pathology records, including patient demographics, tumor type, location, and histopathological characteristics. The analysis reveals a significant prevalence of astrocytic tumors in the frontal lobes for both male and female patients, with glioblastoma multiforme being the most common tumor type. The study also highlights the impact of tumor location on the presentation and progression of psychiatric symptoms, underscoring the need for tailored treatment approaches. **Conclusions:** These findings contribute to a better understanding of the relationship between tumor location, patient outcomes, and the potential for targeted therapeutic strategies. **Keywords:** ASTROCYTIC TUMORS, BRAIN METASTASES, ANATOMICAL LOCATION, GLIOBLASTOMA, HISTOPATHOLOGICAL ANALYSIS.FRONTAL LOBE TUMORS, TEMPORAL LOBE TUMORS, PARIETAL LOBE TUMORS, TUMOR DISTRIBUTION.

Astrocytomas are a group of brain tumors that most commonly affect individuals between the ages of 30 and 40, with a slightly higher incidence in men. High-grade tumors, such as glioblastomas, are the most common malignant brain tumors, accounting for approximately 54% of all gliomas and 16% of all primary brain tumors (1, 2). Symptoms of low-grade astrocytomas may be subtle, as the brain can temporarily compensate for the slow growth of the tumor. In contrast, high-

grade tumors can cause acute and severe symptoms, such as headaches, seizures, and personality changes (3, 5).

The treatment of astrocytic tumors requires a multidisciplinary approach, involving surgical interventions, chemotherapy, and radiotherapy. For low-grade tumors, complete surgical resection is often curative, with radiotherapy used in cases of tumor recurrence or progression (7). High-grade tumors typically require a combination of maximal surgical resection and radiochemotherapy (8). Despite technological advancements and the identification of molecular markers that have improved prognostic stratification, managing these complex tumors remains challenging (9, 10).

This study aims to investigate the anatomical distribution of astrocytic tumors and brain metastases in the frontal, parietal, and temporal lobes, analyzing the impact of these locations on pre-diagnosed psychiatric symptoms. The study contributes to a better understanding of tumor behavior and the improvement of personalized therapeutic approaches.

SIGNS AND SYMPTOMS

The signs and symptoms of grade I and grade II astrocytomas are difficult to observe, as the brain can temporarily adapt to the presence of a slow-growing tumor. The signs of grade III and IV astrocytomas can appear suddenly and can strongly affect the body (5). The symptoms and signs of brain tumors result in a general increase in intracranial pressure, focal changes in brain function, or, in some cases, a combination of both (6).

Headache is one of the main symptoms often associated with brain tumors (7). The usual pain is felt bilaterally in the frontal area (8), is non-throbbing in quality (9), and is moderate in intensity. Headache is often accompanied by other symptoms that indicate a diverse impairment of intracranial structures, such as personality changes, seizures, and/or specific neurological signs, along with signs of increased intracranial pressure (nausea, vomiting, optic nerve swelling, blurred vision) (7).The exact location of the tumor cannot be predicted just based on the location of the headache, but a predilection for frontal headaches is observed in supratentorial and skull base tumors, while occipital headaches are more commonly found in infratentorial tumors (9). According to a study conducted by Lowry and his colleagues (10), headaches were much more common in patients under the age of 45 suffering from a malignant primary brain tumor, compared to those aged 65 or older.

Cranial tumors can cause severe ocular manifestations and symptoms in addition to the neurological consequences caused by increased pressure inside the cranium, nerve damage or brain compression (11). Common initial symptoms include gradual decrease in visual acuity, possible optic nerve atrophy, visual field impairment, and paralysis of the extraocular nerves (12).

TREATMENT

A team consisting of oncologists, radiologists, and neurosurgeons with individualized experience make treatment decisions. The treatment is determined by the type and location of the tumor, the degree of malignancy, the age, and the health condition of the patient (13). Chemotherapy, radiotherapy, and surgical intervention are the three most commonly used treatment options. In cases where brain tumors are benign, surgical intervention can be effective (14).

Pilocytic astrocytoma has a low rate of malignant progression. The main treatment is surgical resection. Radiotherapy is indicated for the area affected by the tumor in the absence of other surgical options and if there are radiographic evidence of progression (15). The removal of grade II tumors is achieved through microsurgical intervention. Radiation therapy may be recommended for patients who have undergone partial surgical intervention, have observed tumor growth, or cannot undergo surgery (16). Radiochemotherapy may be postponed until disease progression, as surgical intervention is potentially curative (17).

The maximum safe resection of grade III tumors, followed by radio chemotherapy, is considered standard in their treatment (18). Temozolomide administered together with radiotherapy does not have a significant additional effect (19). Current technological and conceptual advances have increased the safety of surgical procedures, while also expanding the possibilities and indications for surgery in the treatment of grade IV tumors (20). Usually radiotherapy follows surgery in most cases. Chemotherapy can sometimes be administered together with or after radiotherapy. However, there is no standard chemotherapy treatment protocol, and each regimen must be customized for each patient (21).

Low grade tumors can be approached through various methods, such as the administration of anticonvulsant/antiepileptic drugs, steroids or surgical interventions. Studies have found that between 30-50% of individuals diagnosed with brain tumors experience at least one seizure, while 10-30% of them face repeated convulsions (22). Nowadays, all those diagnosed with brain tumors should receive treatment with antiepileptic drugs due to the frequency of seizures associated with these tumors (23).

The therapy for neuropsychiatric symptoms involves both medications and non-pharmacological therapies. Non-pharmacological interventions require collaboration efforts from doctors, nurses, and family/caregivers (24). In order to provide the best psychopharmacological and psychotherapeutic intervention, it is essential to assess patients' symptoms through a rigorous neuropsychological and psychiatric evaluation in specialized clinics. Regarding patients' families, the importance of an educational, supportive, and psychosocial-oriented intervention has been consistently highlighted (25, 26). Oncological psychology and social oncology are, compared to biomedical therapies for cancer, new additions in contemporary cancer care (27).

MATERIALS AND METHODS

This retrospective study included 91 patients treated at the "Prof. Dr. N. Oblu" Emergency Clinical Hospital in Iasi, Romania, between February 17th, 2011, and May 8th, 2023. All patients underwent pathological examination of tissue samples removed during surgery. The Pathology Department's biopsy registry recorded the patients' identification details (name, gender, age), the tumor's location and type, and the stains used. Patients were informed about the necessity of histopathological tests and consented to the use of biological material for diagnostic and research purposes.

RESULTS

In this study, we analyzed the distribution of tumors based on their anatomical location, utilizing cerebral MRI and native CT scans for diagnosis. The findings revealed that, for male patients, the left and right frontal lobes were the most common

sites for tumor occurrence, each accounting for 40% of the cases (Fig. 1). This indicates a significant concentration of tumors in these regions compared to other anatomical areas. The next most frequent site was also within the frontal lobe, but with a considerably lower incidence of 7%. This distribution pattern highlights the frontal lobe as a primary site of tumor development in men.

Just like in the case of men, in women most of the tumors are found in the left and right frontal lobes, the percentage being 32% (fig. 2). This finding shows a significant predilection for these areas compared to other anatomical regions. The following areas by frequency are the right fronto-temporal lobe with 4 cases (9%) and the right fronto-parietal lobe with 3 cases (6%). Other observed locations, each with 2 cases (4%), include the left fronto-parietal lobe, the left fronto-temporo-insular lobe, and the left fronto-parieto-temporal lobe.

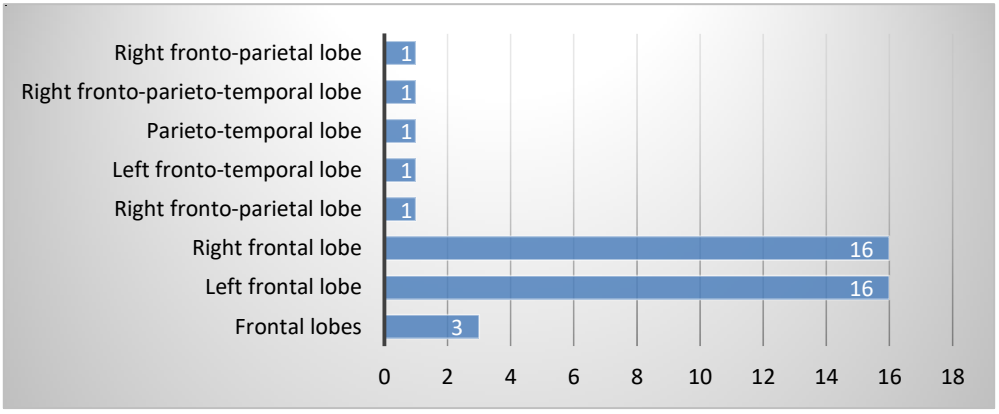

Fig. 1. Distribution of tumors by location in men

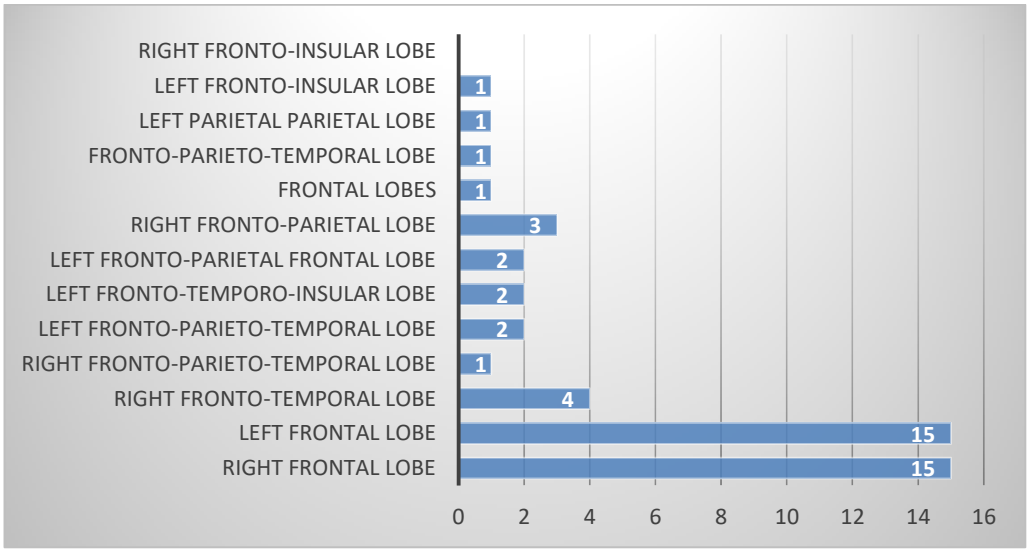

Fig. 2. Distribution of tumors by location in women

Next, we analyzed the distribution of different types of non-metastatic brain tumors, in order to provide a comprehensive perspective on the diversity and frequency of these conditions in our study context (fig. 3).

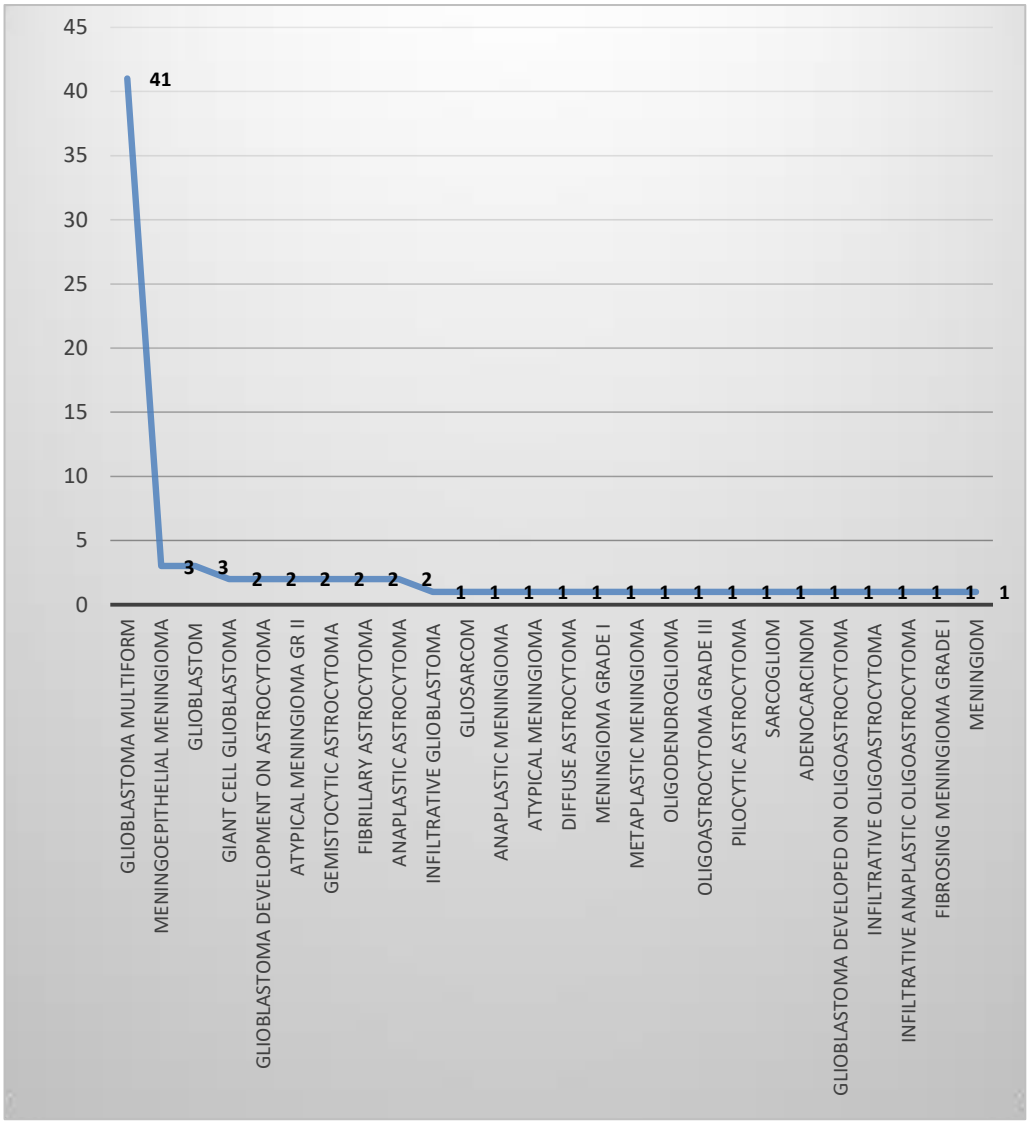

Fig. 3. Distribution of non-metastatic brain tumors

Examining the graph shows that "Glioblastoma Multiforme" is the most common type of tumor, constituting a significant part of the total cases studied, with 41 incidences (55%). Following in second place, at a significant distance, are "Meningoepithelial Meningioma" and "Glioblastoma", each having 3 cases (4%), while "Giant

Cell Glioblastoma" and "Differentiated Glioblastoma on Astrocytoma" have 2 cases each (3%). This distribution highlights the typological variety of non-metastatic brain tumors, with a clear predominance of glioblastoma multiforme.

To complete our analysis, it is essential to examine the distribution of brain metastases according to the affected lobes. This approach allows us to better understand not only the incidence and types of primary tumors, but also how they spread and impact different regions of the brain (fig. 4) illustrates the distribution of brain metastases, providing a clear picture of their prevalence and location within the studied population.

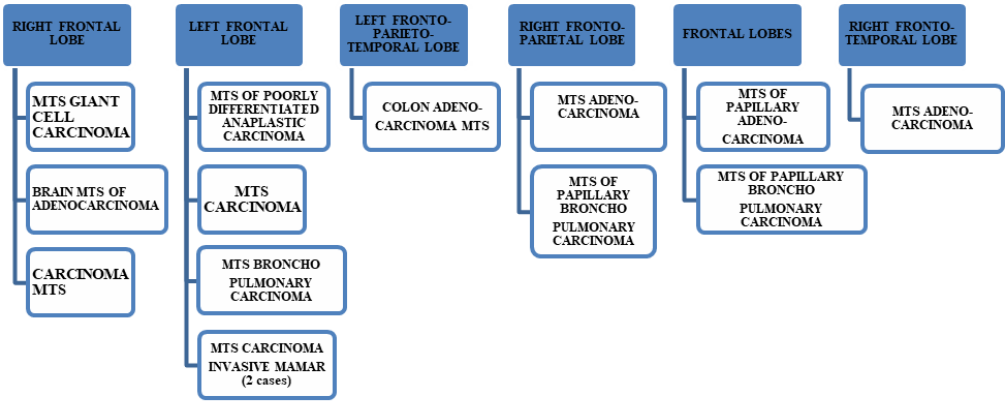

Fig. 4. Distribution of brain metastases (MTS = METASTASIS)

The right and left frontal lobes present the highest diversity of types of metastases, indicating a greater susceptibility of these regions to different types of cancer. In the right frontal lobe, the majority of affected patients are men, which may suggest a higher incidence of brain metastases in this region in men. On the other hand, metastases in the right frontoparietal and left frontoparietotemporal lobes seem to mainly affect women. Metastases from adenocarcinoma and papillary bronchopulmonary carcinoma are common in multiple regions of the brain, demonstrating an increased capacity of these types of cancer to spread to the brain. The frontal lobes (right and left) and frontoparietal lobes are critical regions for cognitive and motor functions. Metastases in these areas can lead to significant neurological deficits, such as movement problems, executive function, and behavior. Metastases in the left frontoparietotemporal lobe can affect language functions and spatial perception, having a major impact on the quality of life of patients. Metastases of adenocarcinoma are common and occur in various regions of the brain, indicating the aggressive and invasive nature of this type of cancer.

To create a more detailed and comprehensive overview of the distribution of non-metastatic brain tumors based on loca-

tion and sex, we have included a table summarizing this information (tab. I). The distribution of these tumors in various regions of the brain is presented for both men and women, offering a comprehensive perspective on the demographic and anatomical differences and similarities of the cases studied.

TABLE I.
Distribution of non-metastatic brain tumors by location and sex

Tumor type	Location	Number of cases	Gender distribution
GLIOBLASTOMA	Frontal lobes	2	M=2
	Right fronto-parietal lobe	1	M=1
	Right frontal lobe	14	W=7; M=7
	Left frontal lobe	18	W=8; M=10
	Right fronto-temporal lobe	2	W=2
	Right fronto-parieto-temporal lobe	2	W=1; M=1
	Left fronto-parieto-temporal lobe	1	W=1
	Left fronto-temporo-insular lobe	2	W=2
	Left fronto-temporal lobe	1	M=1
	Left parietal lobe	1	W=1
	Left fronto-parietal frontal lobe	3	W=1; M=1
	Right fronto-parietal lobe	1	W=1
	Right fronto-insular lobe	1	W=1
	Parieto-temporal lobe	1	W=1
MENINGIOMA	Right fronto-parietal lobe	2	W=2
	Right frontal lobe	6	W=5; M=1
	Fronto-parieto-temporal lobe	1	W=1
	Left frontal lobe	2	W=1, M=1
ASTROCYTOMA	Left frontal lobe	3	W=1; M=2
	Right frontal lobe	3	W=2, M=1
	Right fronto-temporal lobe	1	W=1
	Right fronto-insular lobe	1	W=1
OLIGOASTROCYTOMA	Left frontal lobe	2	W=2
	Right frontal lobe	1	M=1
GLIOSARCOMA	Right frontal lobe	1	W=1
ADENOCARCINOMA	Left frontal lobe	1	M=1
OLIGODENDROGLIOMA	Right frontal lobe	1	M=1
SARCOGLIOMA	Right frontal lobe	1	M=1

W- woman, M- man

Glioblastoma is the most common type of brain tumor in the study, with a total of 50 cases. This suggests a high prevalence of this type of tumor among the patients analyzed. Its distribution is varied in multiple regions of the brain, with the majority of cases being located in the frontal lobe. Glioblastoma is almost equally distributed among men and women. However, a slight predominance of cases in the left frontal lobe in men is observed. These data highlight the importance of carefully analyzing the anatomical distribution of glioblastoma in order to better understand its behavior

and prognosis. There are cases of glioblastoma in various combinations of lobes (e.g. fronto-parieto-temporal), indicating the complexity and extent of these tumors.

Meningioma also appears quite frequently in the dataset, being especially located in the right frontal lobe. This tumor is much more commonly found in women, highlighting their predisposition to developing meningioma compared to men. Specifically, meningioma is predominantly located in the frontal lobe, with a significant concentration on the right side. This trend indicates that women have a higher prevalence for developing this type of tumor in certain regions of the brain.

Oligoastrocytoma, gliosarcoma, adenocarcinoma, oligodendroglioma, and sarcomato-glioma are fewer common tumors, but present, with a variable distribution between sexes and locations, having notable cases, especially in the frontal lobes.

The frontal lobe is generally the most frequent location for tumors in the table, with multiple cases for all types of tumors. Both the right and left frontal lobes are the most common location for tumors. This may indicate a vulnerability or predisposition of this lobe to develop tumors. The distribution of tumors between sexes is relatively balanced for certain types of tumors, such as astrocytoma, but disproportionate for others, such as meningioma.

DISCUSSION

The results of this study highlight a predominant distribution of astrocytic tumors in the frontal lobes for both men and women. This finding aligns with existing literature, which suggests a preference for astrocytoma, particularly glioblastoma, in this brain region (1, 2, 3). The similar distribution between sexes, with a slight predominance in the left frontal lobe in men, emphasizes the need for personalized treatment approaches considering both anatomical location and sex differences.

Our analysis of brain metastases revealed a higher susceptibility of the frontal lobes to various cancer types, particularly metastases originating from adenocarcinoma and papillary bronchopulmonary carcinoma. These findings underscore the complexity of tumor-brain interactions, highlighting the necessity of a multidisciplinary approach to managing both primary tumors and metastases.

The study also found a correlation between tumor location and pre-diagnosed psychiatric symptoms, suggesting that frontal lobe involvement can significantly impact patients' cognitive and behavioral functions. These findings emphasize the importance of rigorous neuropsychiatric evaluations in managing brain tumor patients to optimize their quality of life.

Our study contributes to a better understanding of the anatomical distribution of astrocytic tumors and brain metastases, offering valuable insights for personalized therapeutic approaches. However, further research is needed to explore the underlying biological mechanisms and to validate these findings in larger clinical studies.

CONCLUSIONS

This study presents a detailed exploration of the anatomical distribution of astrocytic tumors and brain metastases, focusing predominantly on the frontal lobes. The results indicate that the frontal lobes are the most common site for these tumors, particularly in men, suggesting a potential anatomical predisposition. The significant presence of glioblastoma multiforme further emphasizes the aggressive nature of

these tumors in this region. These findings underline the critical need for location-specific therapeutic strategies that consider both the type and site of the tumor to enhance patient outcomes.

Additionally, the study draws attention to the importance of using advanced imaging techniques, such as MRI and CT scans, for accurate diagnosis and localization of tumors, which is crucial for effective treatment planning. The variability in tumor types across different brain regions also suggests that personalized treatment protocols are essential to address the unique challenges presented by each tumor's location and characteristics.

Future research should aim to validate these findings in larger cohorts and explore the biological mechanisms that may contribute to the observed distribution patterns. Understanding these mechanisms could lead to the development of more targeted therapies, ultimately improving the prognosis and quality of life for patients with astrocytic tumors and brain metastases.

CONFLICTS OF INTERES AND FUNDING

The authors have declared that there are no conflicts of interest related to this research. Additionally, no external funding was obtained or secured for the study.

MESENCHYMAL STEM CELL'S OSTEOGENIC DIFFERENTIATION IS DEPENDENT ON ENVIRONMENTAL STIMULI (Abstract): Mesenchymal stem cells derived osteoblasts or mesenchymal stem cells osteogenic differentiation could represent an important way to increase the healing after dental implantation. **Aim**: This research investigated the effects of various environmental stimuli (*in vitro*) on the osteogenic differentiation of MSCs and the subsequent development of calcium deposits by these cells. Materials and m**ethods**: Calcium phosphate deposition was quantified using the Alizarin red method via spectrophotometry. **Results**: The calcium deposited solely by mesenchymal stem cells derived osteoblasts was considered to be 100% all the time. When 1% platelet-rich plasma was added in the culture medium, the calcium deposits increased by 20% (on average). Different amounts of calcium deposits were developed by MSCs-derived osteoblasts when platelet-rich plasma was administered concurrently with: rosavin, rapamycin, metformin, "young" exosomes, "adult" exosomes, lower power CO_2 laser, extracellular shock waves, and PI3K/HDAC11 inhibitor. Conversely, platelet-poor plasma did not significantly modify the calcium deposits realized by MSCs-derived osteoblasts. **Conclusions**: All the obtained data suggest that calcium deposits resulting from the functioning of mesenchymal stem cells-derived osteoblasts could be significantly and especially increased by cellular mechanisms related to "young" exosomes, rosavin, acetylation, rapamycin, "adult" exosomes and metformin. **Keywords:** MSC, MSC-iPSC, OSTEOGENIC DIFFERENTIATION, EXOSOMES, PLATELET-RICH PLASMA.

INTRODUCTION

Mesenchymal stem cells (MSCs) are multipotent cells capable of self-renewal and differentiation into a variety of cell types, and they play an important role in tissue repair and regeneration. Cell treatment and tissue engineering primarily use bone marrow-derived mesenchymal stem cells (BMSCs). It is essential for BMSCs to mobilize from bone marrow and further migrate into injured tissues during the healing process via peripheral circulation. The migration of bone marrow stem cells is influenced by both mechanical and chemical factors during the trafficking process. Numerous studies have emphasized the impact of key regulatory factors on BMSC migration and the associated mechanisms. The focus should follow two essential functions of BMSCs: directed differentiation and paracrine signaling in tissue repair. Additionally, it will explore the connection

between BMSC migration and tissue repair, offering valuable guidance for clinical applications aimed at optimizing BMSC migration for enhanced tissue repair outcomes (1).

The aging process causes a variety of cellular alterations, such as high amounts of reactive oxygen species (ROS) in numerous cell types, including MSCs. The link between reactive oxygen species (ROS) and decreased healing capacity is unclear, as is the effect of ROS suppression on the rejuvenation of old MSCs. The regeneration of old MSCs has lately received attention in regenerative medicine. Extracellular vesicles (EVs) may represent a unique technique for stem cell rejuvenation, as they can allow gene transfer with effects throughout the body and are associated with a high degree of therapeutic safety. The data revealed that aged MSCs had lower levels of superoxide dismutase (SOD)1 and SOD3, which led to an increase in reactive oxygen species (ROS) and a decrease in the MEK/ERK pathways. This limitation hampered the MSCs' ability to diminish necrotic area in the skin flap model. Furthermore, the treatment with the antioxidant Edaravone or co-overexpression of SOD1 and SOD3 reduced ROS levels and cellular senescence in old MSCs, resulting in better functioning. Infant MSC-derived EVs significantly revitalized aged MSCs by reducing ROS production, decreasing cellular senescence, and increasing proliferation and in vivo activities in both type 1 and type 2 diabetic mice (2).

MSCs are multipotent stem cells that have garnered considerable interest in regenerative medicine. The differentiation potential and paracrine properties of MSCs render them a significant choice for tissue repair. Consecutively, the paracrine functions of MSCs involve the secretion of soluble factors and the release of extracellular vesicles, including exosomes and microvesicles. Extracellular vesicles primarily originate from endosomes and carry a cargo of miRNA, mRNA, and proteins, which are transferred from donor cells to recipient cells. Recent findings indicate that extracellular vesicles are solely responsible for the therapeutic effects of mesenchymal stem cells in numerous animal disease models. Therefore, MSC-derived extracellular vesicles could serve as an alternative MSC-based therapy in the field of regenerative medicine (3).

Alveolar bone deficiency presents a significant clinical challenge in maxillofacial reconstructive surgery. The existing surgical techniques for extracortical bone augmentation exhibit a degree of unpredictability and often fail to meet expectations. Several studies sought to quantify extracortical bone augmentation and tissue mineral density (TMD) following the co-transplantation of peripheral blood-derived endothelial progenitor cells (EPCs) and, the same time, of bone marrow-derived MSCs using microcomputed tomography (micro-CT). Micro-CT analysis revealed that the co-transplantation of EPCs and MSCs significantly enhanced bone formation and mineral density (4).

BMSCs possess the capability to differentiate into adipocytes and osteoblasts. External stimuli, such as environmental contaminants, heavy metals, dietary factors, and physical influences, significantly affect the pathway decision of BMSCs regarding adipogenesis or osteogenesis. The equilibrium between osteogenesis and adipogenesis is essential for bone homeostasis, and disruptions in the lineage commitment of BMSCs are linked to various

health problems, including fractures, osteoporosis, osteopenia, and osteonecrosis. Further research is required to comprehend the effects of these external stimuli on bone health and to clarify the mechanisms underlying the differentiation of BMSCs. This knowledge will guide initiatives aimed at preventing bone-related diseases and formulating therapeutic strategies for treating bone disorders linked to diverse pathological conditions and implants (5).

This research investigated the effects of various environmental stimuli (*in vitro*) on the osteogenic differentiation of mesenchymal stem cells and these cells' subsequent development of calcium deposits.

MATERIALS AND METHODS

The laboratory study sought to quantify calcium deposition resulting from the osteogenic differentiation of mesenchymal stem cells in response to various environmental stimuli and different culture mediums. Calcium phosphate deposition was quantified using the Alizarin red method via spectrophotometry (6).

MSCs were isolated as outlined in prior research (7). Additionally, mesenchymal stem cell-derived induced pluripotent stem cells (MSC-iPSCs) were developed using the episomal technique with iPSC reprogramming vectors and the designated Stemline culture media (Invitrogen), adhering to the manufacturer's guidelines. MSC-iPSCs were utilized to isolate exosomes characterized as "young". Conversely, standard MSCs were utilized to derive "adult" exosomes.

The osteogenic differentiation of the MSCs followed a straightforward and effective method (6). Cell viability was assessed using Evans blue exclusion.

The preparation of the platelet-rich plasma (PRP) gel was conducted as outlined in previous studies (8), with a delivery concentration of 1%. The PRP gel was compared to the PPP (platelet-poor plasma).

The culture medium of pluripotent stem cells derived from rat mesenchymal stem cells was subjected to centrifugation at 100,000xg for exosome separation (9).

The compounds, preparations, and methods utilized in the tests and protocols for mesenchymal stem cells' osteogenic differentiation included: 1 µM rosavin (adaptogen), 1 µM rapamycin, 1 µM metformin, "young" and "adult" 0.01% exosomes, lower power CO2 laser, 1% platelet-rich plasma, 1% platelet-poor plasma, extracellular shock waves (1,000 pulses at an energy of 0.3 mJ/mm^2 at 24 and 72 hours), and 1 µM PI3K/HDAC11 specific inhibitor.

Data were verified through additional methods, including epifluorescence, confocal microscopy, and gene expression analysis using the Profiler 725 antibody microarray.

All experimental results from the current study were analyzed using established statistical methodologies, employing various optimized tests recognized in medical research. Notably, the One-Way ANOVA test was utilized, occasionally supplemented by the Student-Newman-Keuls test.

All experiments received approval from the Ethics Committee of the "Grigore T. Popa" University of Medicine and Pharmacy Iaşi.

RESULTS

The optimal qualitative and quantitative development of pluripotent stem cells, experimentally reprogrammed from mesenchymal stem cells, and mesenchymal stem cells, initiated from the second passage in culture, was achieved when cultured in a

preconditioning medium with 1% O2, as previously demonstrated. A 100% increase was consistently assumed (n=5 experiments per set, data not presented, personal observation).

The calcium deposited solely by mesenchymal stem cells derived osteoblasts (aka osteoblasts) was considered to be 100% all the time (control, Ctrl, 7 experiments, as average). When PRP 1% was added in the culture medium, the calcium deposits increased by 20% (on average, Ctrl PRP, fig. 1). By contrast, PPP did not significantly modify the calcium deposits realized by mesenchymal stem cells derived osteoblasts.

In the first series of tests, mesenchymal stem cells derived osteoblasts were treated with 1 µM rosavin and 1% platelet-rich plasma (PRP). The deposited calcium, evaluated through Alizarin red, showed an increase of 36% as compared to the control PRP (on average, fig. 1).

In the second series of tests, a separate batch of mesenchymal stem cells derived osteoblasts was treated with 1 µM rapamycin and 1% platelet-rich plasma. Mesenchymal stem cells derived osteoblasts showed an average 27% increase in calcium deposits as compared to control PRP (on average, fig. 1).

In the third series of tests, a new number of derived osteoblasts were treated with 1 µM metformin and 1% platelet-rich plasma. We observed a 23% increase in calcium deposited by mesenchymal stem cells derived osteoblasts as compared to control PRP (on average, fig. 1).

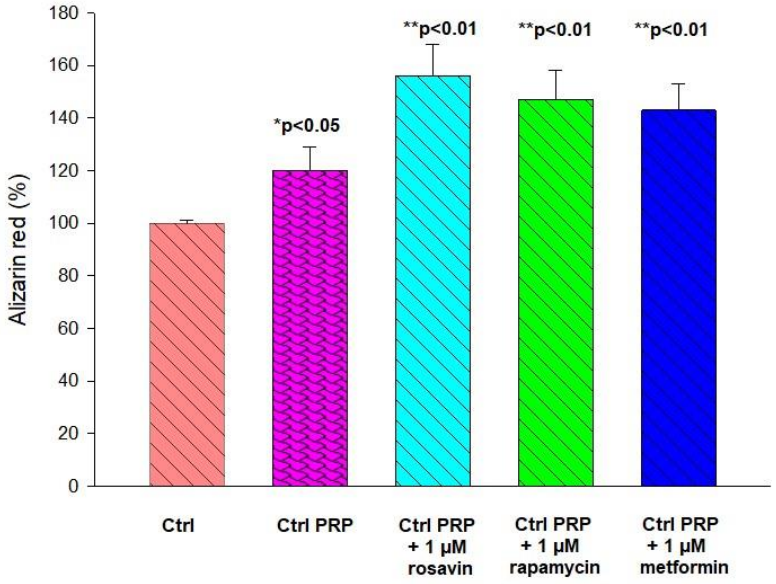

Fig. 1. Determination of calcium deposited by mesenchymal stem cells derived osteoblasts (Ctrl), in the presence of 1% PRP (Ctrl PRP), as well treated with rosavin, rapamycin, and metformin. (*p<0.05 as compared to the solely derived osteoblasts. **p<0.01 as compared to the solely mesenchymal stem cells derived osteoblasts)

In the fourth series of studies, a completely separate batch of derived osteoblasts was treated with 0.01% "young" exosomes obtained from MSC-iPSC supernatant and 1% PRP. In this case, we observed an average of 42% augmentation in calcium deposits as compared to control PRP (on average, fig. 2).

In the fifth series of tests, mesenchymal stem cells derived osteoblasts were treated with 0.01% "adult" exosomes obtained from MSC supernatant and 1% platelet-rich plasma. We observed a 25% growth in deposited calcium as compared to control PRP (on average, fig. 2).

In the sixth series of studies, a separate batch of derived osteoblasts was treated with lower power CO_2 laser for 1 minute, 7 pulses in one day, and 1% platelet-rich plasma. We thus observed a modest 5% augmentation in deposited calcium as compared to control PRP (on average, fig. 2).

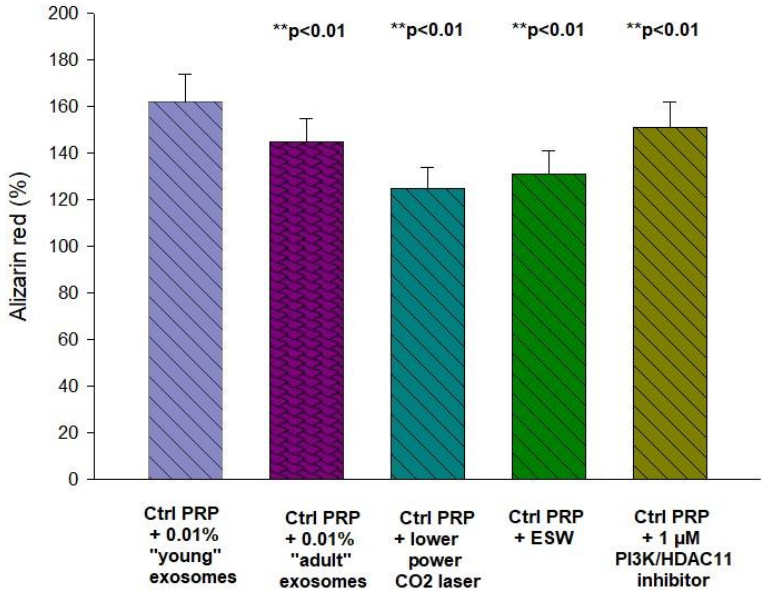

Fig. 2. Measurement of calcium deposited by mesenchymal stem cells derived osteoblasts in the presence of 1% PRP (Ctrl PRP) and as well treated with 0.01% "young" exosomes, 0.01% "adult" exosomes, lower power CO_2 laser, extracellular shock waves, 1 μM PI3K/HDAC11 specific inhibitor (**p<0.01 as compared to the solely mesenchymal stem cells derived osteoblasts)

In the seventh series of tests, a different number of osteoblasts were treated with extracellular shock waves (1000 pulses at an energy of 0.3 mJ/mm^2 at 24 and 72 hours) and 1% PRP. We observed an average increase of 11% of deposited calcium by mesenchymal stem cells derived osteoblasts as compared to control PRP (on average, fig. 2).

In the eighth series of trials, a completely separate batch of osteoblasts was treated with 1 μM PI3K/HDAC11 specific inhibitor and 1% platelet-rich plasma. We observed a 31% augmentation of calcium

deposited by mesenchymal stem cells derived osteoblasts as compared to control PRP (on average, fig. 2).

DISCUSSION

Our research was based on the fact that the differentiation of mesenchymal stem cells into osteoblasts is commonly conducted in research laboratories. Traditional methods utilized to demonstrate this differentiation utilize steps such as cell fixation, cell lysis, or cell scraping. Limited research addresses the gentle dissociation of mesenchymal stem cells during the osteo differentiation process. Consequently, the cells undergoing differentiation established one layer in neurogenic differentiation, two layers in adipogenic differentiation, and a minimum of four layers in osteogenic differentiation. The upper layers, supported by a collagen I extracellular matrix, can be dissociated with collagenase I, whereas the lowest layer, adhering to the dish bottom, is only sensitive to trypsin-versene. Collagenase I exhibit greater efficiency prior to the mineralization of the extracellular matrix. The collagenase-sensitive and trypsin-sensitive layers exhibit differences in their cluster of differentiation expression. The dissociation of the cells on day 15 indicates that they can resume growth (increase in cell number) and rapidly differentiate into osteoblasts within 2 weeks, rather than the previously observed 4 weeks. Cells from the upper layers exhibited increased mineralization. MSCs that undergo osteogenic differentiation develop multiple layers, each exhibiting unique osteogenic characteristics. This approach may enable investigators to utilize the upper layers for the rapid production of differentiated osteoblasts, while the lower layer can sustain growth and differentiation until subsequent dissociation occurs (6).

Our experimental data showed osteoblasts derived from mesenchymal stem cells being able to deposit calcium in higher amounts, approximately 36%, in the presence of rosavin and platelet-rich plasma (PRP). Rosavin, a phenylpropanoid found in *Rhodiola rosea's* rhizome, functions as an adaptogen and is known to improve the body's reaction to environmental stresses. It has a profound impact on cellular metabolism in both health and disease, particularly the metabolism of bone tissue. In vitro studies show that rosavin inhibits osteoclastogenesis, disrupts F-actin ring formation, and decreases the expression of osteoclastogenesis-related genes like cathepsin K, calcitonin receptor (CTR), as well as tumor necrosis factor receptor-associated factor 6 (TRAF6), but also tartrate-resistant acid phosphatase (TRAP), and matrix metallopeptidase 9 (MMP-9). It blocks bone resorption by inhibiting signaling pathways such as NFATc1, c-Fos, NF-κB, and MAPK. Rosavin also enhances osteogenesis and osteoblast differentiation by raising the expression of mouse runt-related transcription factor 2 (Runx2) and osteocalcin (OCN). In vivo studies show that it improves bone mineral density (BMD) in postmenopausal osteoporosis (PMOP) mice by decreasing osteoclast maturation and boosting the proportion of active osteoblasts in bone tissue. It modulates mRNA expressions by enhancing eukaryotic translation elongation factor 2 (EEF2) and reducing histone deacetylase 1 (HDAC1), thus activating osteoprotective epigenetic mechanisms. It alters serum markers, lowering CTX-1, TRACP5b, RANKL, M-CSF, and TRAP while increas-

ing ALP and OCN. Combining zinc and probiotics reduces pro-osteoporotic MMP-3, IL-6, and TNF-α levels while increasing anti-osteoporotic IL-10 and TIMP3 expression (10).

Rhodiola rosea, a perennial herb of the Crassulaceae family, contains the active component salidroside, which is recognized as an adaptogen with significant therapeutic promise for bone metabolism. Salidroside promotes osteoblast proliferation and differentiation by activating critical signaling pathways, and we can highlight the bone morphogenetic protein-2 and adenosine monophosphate-activated protein kinase, which both are essential for bone production and growth. Moreover, it enhances osteogenic activity by increasing alkaline phosphatase activity and mineralization indicators, as well as upregulating important regulatory proteins such as runt-related transcription factor 2 and osterix. Salidroside stimulates angiogenesis via the hypoxia-inducible factor 1-alpha and vascular endothelial growth factor pathways, which are critical for connecting bone formation and vascular supply. The antioxidant qualities prevent bone loss by reducing oxidative stress and promoting osteogenic differentiation through the nuclear factor erythroid 2-related factor 2 pathway. Salidroside can reduce the negative effects of glucocorticoids on bone cells and prevent steroid-induced osteonecrosis. Furthermore, it displays complicated anti-inflammatory actions, mainly by suppressing the expression of tumor necrosis factor-alpha and interleukin-6, while boosting the expression of interleukin-10 (11).

Cells detect mechanical signals from the extracellular matrix to modulate cellular activities and preserve tissue homeostasis. The nucleus serves as a crucial mechanosensor, directly affecting chromatin organization, epigenetic modifications, and gene expression. Nuclear mechanosensing dysregulation has been associated with various diseases, including bone degeneration. Some studies utilized photo-stiffening hydrogels to modulate nuclear mechanosensing in human mesenchymal stem cells (hMSCs) *in vitro*. The findings indicate that human mesenchymal stem cells (hMSCs) react to matrix stiffening by enhancing nuclear tension, which leads to an increase in histone acetylation through the deactivation of histone deacetylases (HDACs). This leads to the commitment to an osteogenic pathway. Disruption of nuclear mechanosensing through the disconnection of the nucleus from the cytoskeleton leads to the upregulation of HDACs and inhibits osteogenesis. Restoring HDAC activity to normal levels improves the epigenetic and osteogenic response in hMSCs exhibiting pathological nuclear mechanosensing. Bone from patients with osteoarthritis exhibits comparable deficiencies in nuclear mechanosensing. The results indicate that nuclear mechanosensing regulates the osteogenic potential of hMSCs through HDAC epigenetic remodeling, suggesting its relevance to bone-related diseases (12).

The secretomes of MSCs represent a unique approach to growth factor administration in tissue regeneration. The purpose of some studies was to compare the efficacy of conditioned media derived from bone-marrow mesenchymal stem cells (MSC-CM) when used with collagen barrier membranes to conditioned media derived from leukocyte- and platelet-rich fibrin (PRF-CM), a modern growth-factor therapy, for guided bone regeneration. Both

MSC-CM and PRF-CM showed a variety of bone-related proteins; however, MSC-CM had a larger increase in differentially expressed proteins, particularly those linked with extracellular matrix components. Micro-CT study of rat calvaria defects revealed that the MSC-CM group had better total bone covering at both 2 and 4 weeks. Histological investigation revealed that both groups had a mix of conventional and 'hybrid' new bone, with the latter generated within the membrane compartment and distinguished by the incorporation of mineralized collagen fibers. Histomorphometry study of central defect sections revealed that the MSC-CM group had more hybrid bone area, although the total new bone area was equivalent across all groups. In vitro and in vivo studies indicate that membrane functionalization with MSC-CM is a viable technique for improving GBR (13).

Moreover, rapamycin, a modulator of autophagy and mTOR pathways, was able to increase the calcium deposition of derived osteoblasts by 27% (on average) in our experiments. Autophagy is crucial for the self-renewal and differentiation of stem cells; however, its impact on BMSCs is not well understood. Several studies have focused on examining the relationship between autophagy and osteogenic differentiation through the use of rapamycin (RAPA), a well-known autophagy agonist with osteo-regulatory properties. The basal autophagy level in BMSCs progressively declined during osteogenic differentiation, characterized by a reduction in BECN1 levels, a decrease in the ratio of lipidated (LC3-II) to unlipidated (LC3-I) microtubule-associated protein 1 light chain 3, and an elevation in the expression of the selective autophagic target p62. Conversely, it rose with higher RAPA concentrations. Additionally, 2 nM RAPA facilitated BMSC osteogenic differentiation on days 7 and 14, whereas 5 nM RAPA suppressed osteogenesis on days 14 and 21. The use of the autophagy inhibitor 3-methyladenine may diminish the osteogenesis-promoting effect of RAPA on BMSCs. The basal autophagy level in BMSCs diminished progressively throughout the process of osteogenic differentiation. An appropriate RAPA concentration facilitated BMSC osteogenic differentiation through the activation of autophagy (14).

Therefore, metformin, which increases and decreases histone acetylation, histone and DNA methylation, and gene expression, augmented the calcium deposition of derived osteoblasts by 23% (on average), as demonstrated by our experiments. Periodontitis is the sixth leading cause of tooth loss in diabetic patients. Metformin stimulates the osteogenic differentiation of stem cells. So, periodontal ligament stem cells (PDLSCs) are the best stem cell type for periodontal tissue regeneration. The purpose of the study was to see how metformin might affect the proliferation, migration, and osteogenic differentiation of periodontal ligament stem cells (PDLSCs) in vitro. PDLSCs were isolated by limiting dilution, and their properties were determined using colony formation assays and flow cytometry. Metformin's effects on cell proliferation and migration were evaluated using cell counting and migration assays. The osteogenic differentiation capacity of PDLSCs was assessed using alkaline phosphatase (ALP) activity and Alizarin Red S staining. Gene expression was measured using a quantitative real-time polymerase

chain reaction (qRT-PCR), and protein levels of osteogenesis-related indicators were assessed using western blotting. Metformin therapy at 10 μM did not impact PDLSC proliferation. However, at 50 and 100 μM, metformin gradually increased PDLSC proliferation, leading to a substantial increase in cell counts after 5 and 7 days of stimulation ($P < 0.05$). Metformin at 50 μM had the strongest effect on migration, ALP activity, and mineral deposition ($P < 0.05$). Metformin at 50 μM significantly increased gene expression for ALP, BSP, OPN, OCN, and Runx2, as well as protein expression for ALP and Runx2 (15).

We observed that there is a clear difference between the effects of „young" exosomes, obtained from the supernatant of mesenchymal stem cells-induced pluripotent stem cells, and "adult" exosomes, isolated from the supernatant of mesenchymal stem cells, on calcium deposition of derived osteoblasts (42% *vs.* 25% on average). The aging global population leads to a higher prevalence of osteoporosis and related fragility fractures, which considerably affects patient quality of life and healthcare expenditures. The acute inflammatory response is crucial for initiating the healing process following injury. Aging is linked to "inflammaging" which denotes the existence of systemic low-grade chronic inflammation. Chronic inflammation hinders the onset of bone regeneration in elderly individuals. Aged macrophages exhibit heightened sensitivity and responsiveness to inflammatory signals. M1 macrophages are activated during the acute inflammatory response; however, the effective resolution of inflammation requires the repolarization of pro-inflammatory M1 macrophages to an anti-inflammatory M2 phenotype, which is linked to tissue regeneration. In aging, chronic inflammation persists due to the failure of M1 to M2 repolarization, resulting in heightened osteoclast activation and reduced osteoblast formation. This imbalance increases bone resorption while decreasing bone formation during the healing process. Inflammaging can hinder the capacity of stem cells to facilitate bone regeneration, contributing to the reduction in bone mass and strength associated with aging. Modulating inflammaging represents a promising strategy for enhancing bone health in the aging population. MSCs exhibit immuno-modulatory properties that could enhance bone regeneration during inflammatory conditions. Preconditioning mesenchymal stem cells with pro-inflammatory cytokines influences their secretory profile and osteogenic capacity. MSCs cultured in hypoxic environments exhibit enhanced proliferation rates and elevated secretion of growth factors. The local delivery of anti-inflammatory cytokines for the resolution of inflammation represents a potential therapeutic approach for bone regeneration in the context of inflammaging. Scaffolds incorporating anti-inflammatory cytokines, unmodified MSCs, and genetically engineered MSCs possess potential therapeutic applications. MSC exosomes enhance the migration of MSCs to fracture sites and promote osteogenic differentiation and angiogenesis. In conclusion, inflammaging may hinder the effective initiation of bone regeneration in the elderly. Modulating inflammaging represents a promising strategy for enhancing impaired bone healing in the elderly population (16).

Conversely, the lower power CO_2 laser, which may exhibit bio stimulatory effects

on cells viability, presented modest effects on calcium deposition by derived osteoblasts (5% on average). Low-level laser treatment (LLLT) has been found to promote fibroblast vitality. Secretomes can be added to culture media using conditioned medium made from BMSCs. Some studies looked at the effect of low-level laser therapy (LLLT) as well as hBMSCs' conditioned medium on the vitality of human dermal fibroblasts (HDFs) cultivated in a high-glucose (HG) medium. For four days, the HDFs were grown in either standard glucose (5.5 mM/l) or high glucose media (15 mM/l). Low-level laser therapy (LLLT) used a continuous-wave helium-neon laser (632.8 nm) with a power density of 0.00185 W/cm² and energy densities of 0.5, 1, and 2 J/cm². Human dermal fibroblasts' high glucose culture media received around 10% of the conditioned medium from human bone marrow-derived mesenchymal stem cells. The vitality of HDFs was assessed using the dimethylthiazol-diphenyltetrazolium bromide (MTT) assay. Laser treatment of HG HDFs at 0.5 or 1 J/cm² resulted in considerably higher cell viability compared to control groups. HG-treated HDFs had considerably reduced cellular viability than LLLT + HG HDFs, hBMSCs condition medium-treated HG HDFs, and LLLT + hBMSCs' condition medium-treated HG HDFs. Finally, both hBM-MSC-conditioned medium and low-level laser therapy improved the survival of hyperglycemic human dermal fibroblasts. The combination of hBMSCs' condition medium with LLLT produced better results than the conditioned medium (17).

Furthermore, extracellular (extracorporeal) shock waves, known to modulate the Ca^{2+} ionic channels, has a slight effect on calcium deposition by obtained osteoblasts (11% on average). Extracorporeal shock wave therapy (ESWT) has been shown to enhance the differentiation of osteoblasts. The impact of ESWT on osteoclast differentiation remains unclear. ESWT has been shown to enhance the process of bone formation. However, the detailed mechanism has not been fully elucidated. Some studies demonstrate that ESWT enhances osteoblast formation *in vitro*. Localized ESW treatment of the femur enhanced *in vivo* bone formation. Moreover, altering the density or frequency of energy did not yield a statistically significant difference in osteogenic differentiation. Local ESW therapy effectively alleviated bone loss and enhanced the quantity of bone trabecular in a rabbit model of osteoporosis, while also promoting endogenous SMAD2 protein expression levels. ESWT may serve as a potential therapy by facilitating osteoblast maturation via the TGF-β/SMAD2 pathway (18).

As a final mention, PI3K/HDAC11 inhibitor, known to act selectively through the inhibition of HDAC11, thus modulating cellular acetylation processes, increased the calcium deposits by 31% on average. Histone deacetylase (HDAC) is an important target in cancer treatment. HDAC inhibitors' key anticancer actions include the stimulation of terminal differentiation and the reduction of cell growth. This study looks into the role of HDAC in sustaining self-renewal and cell proliferation in MSCs either from adipose tissue or umbilical cord blood, using valproic acid (VPA) and sodium butyrate (NaBu). VPA and NaBu altered the shape of MSCs and hindered their proliferation. VPA and NaBu promoted p21 (CIP1/WAF1) transcription by boosting

histone H3 and H4 acetylation, resulting in cell cycle arrest at the G2/M phase. After treatment with an HDAC inhibitor, the expression of p16(INK4A), a cyclin-dependent kinase inhibitor associated to cellular senescence, remained constant. Controlled differentiation into bone, fat, cartilage, and nerve tissue was used to determine the role of HDAC in MSC pluripotency for differentiation into functional tissues. VPA and NaBu reduced the effectiveness of adipogenic, chondrogenic, and neurogenic development, as demonstrated by specific staining and reverse transcription-polymerase chain reaction. Treatment with HDAC inhibitors increased osteogenic differentiation (19).

CONCLUSIONS

The calcium deposited solely by mesenchymal stem cells derived osteoblasts (aka osteoblasts) was considered to be 100% all the time. When 1% platelet-rich plasma was added in the culture medium, the calcium deposits increased by 20% (on average). Different amounts of calcium deposits were developed by mesenchymal stem cells derived osteoblasts when platelet-rich plasma was administered concurrently with: rosavin (a phenylpropanoid in *Rhodiola rosea*'s rhizome, and an adaptogen, +36% on average); rapamycin (a modulator of autophagy and mTOR pathways, +27% on average); metformin (which increase and decrease histone acetylation, histone and DNA methylation, and gene expression, +23% on average); „young" exosomes (obtained from the supernatant of mesenchymal stem cells-induced pluripotent stem cells, +42% on average); „adult" exosomes (isolated from the supernatant of mesenchymal stem cells, +25% on average); lower power CO_2 laser (may exhibit bio stimulatory effects on cells viability, +5% on average); extracellular (extracorporeal) shock waves (modulates the Ca^{2+} ionic channels, +11% on average); and PI3K/HDAC11 inhibitor (by selectively inhibiting HDAC11, it modulates cellular acetylation processes, +31% on average). Conversely, platelet-poor plasma did not significantly modify the calcium deposits realized by mesenchymal stem cells derived osteoblasts.

All of these findings suggest that calcium deposits resulted from the functioning of mesenchymal stem cells derived osteoblasts (aka osteoblasts) could be significantly and especially increased by cellular mechanisms related to "young" exosomes, rosavin, acetylation, rapamycin, "adult" exosomes and metformin.

RISK FACTORS OF ANASTOMOTIC FISTULAS AFTER ESOPHAGEAL AND GASTRIC CANCER SURGERY: A RETROSPECTIVE STUDY (Abstract): Anastomotic fistulas remain one of the most severe complications following esophageal and gastric cancer surgery, significantly impacting morbidity and mortality rates. **Materials and methods**: This retrospective study evaluates the risk factors associated with anastomotic fistula formation and assesses the efficacy and complications of esophageal stenting as a treatment modality. Data from 110 patients treated at the Surgery Clinic of "Sf. Maria" Hospital in Bucharest, between 2019 and 2023 were analyzed. The study population was divided into two groups: patients with postoperative anastomotic fistulas who underwent endoscopic esophageal stenting and those who did not develop fistulas. **Results:** Key findings indicate that advanced age, smoking, alcohol consumption, tumor size, TNM stage, hypertension, diabetes, and preoperative radiotherapy were significantly associated with an increased risk of fistula formation. Additionally, hypoalbuminemia, anemia, and impaired renal function emerged as critical predictors. While esophageal stenting proved to be an effective intervention, it was associated with specific complications requiring careful patient selection and monitoring. **Conclusions:** This study identifies multiple risk factors associated with the development of anastomotic fistulas after esophageal and gastric cancer surgery. Understanding these risk factors is crucial for identifying high-risk patients and implementing targeted perioperative strategies to improve surgical outcomes and reduce postoperative complications. **Keywords:** ANASTOMOTIC FISTULA, ESOPHAGEAL CANCER, GASTRIC CANCER, RISK FACTORS.

INTRODUCTION

Anastomotic fistulas are among the most serious postoperative complications following esophageal and gastric cancer surgery, significantly contributing to increased morbidity, prolonged hospitalization, and higher mortality rates. These fistulas result from impaired healing at the anastomotic site, leading to leakage, infection, and subsequent complications. Identifying risk factors associated with anastomotic fistula formation is crucial for optimizing surgical strategies and improving patient outcomes (1, 2).

Numerous factors have been implicated in the development of anastomotic fistulas, including patient-related parameters (age, comorbidities, nutritional status), tumor

characteristics (size, location, histopathology), and perioperative factors (neoadjuvant therapy, intraoperative technique). Despite advances in surgical techniques and perioperative management, the incidence of anastomotic fistulas remains significant, warranting further investigation into modifiable and non-modifiable risk factors (3-5).

The aim of this study is to evaluate the risk factors associated with the development of postoperative anastomotic fistulas in patients undergoing surgery for esophageal and gastric neoplasms. By comparing patients who developed fistulas with those who did not, we seek to identify key predictors that may contribute to an increased risk of fistula formation. A better understanding of these factors could support the development of preventive strategies and guide clinical decision-making in high-risk patients.

MATERIALS AND METHODS

This retrospective and observational study aimed to evaluate the efficacy and complications of esophageal stenting in the treatment of postoperative anastomotic fistulas in patients who underwent surgery for esophageal and gastric neoplasms. The analysis was conducted based on data from patients admitted to the Surgery Clinic of "Sf. Maria" Hospital in Bucharest, between 2019 and 2023. Data collection and processing were carried out during 2023-2024.

The studied population was divided into two groups:

- Study group: Patients who developed postoperative anastomotic fistulas and were treated with endoscopic esophageal stenting.
- Control group: Patients who underwent surgery for esophageal and gastric neoplasms but did not develop postoperative fistulas.

Patients aged ≥18 years with a histopathological confirmed diagnosis of esophageal or gastric neoplasm. The study group includes patients with imaging-confirmed anastomotic fistulas, while the control group consists of those without anastomotic fistulas. Patients with insufficient medical data are excluded.

The study was conducted in compliance with all national and international ethical research standards to ensure the integrity of the research process and patient protection. The study adhered to Law No. 206/2004 on good conduct in scientific research, technological development, and innovation, which defines ethical and integrity standards for research activities in Romania. The principles of the Declaration of Helsinki were implemented to uphold ethical research practices in human subjects. Fundamental ethical principles, such as confidentiality protection and respect for patient rights, were followed throughout the study.

RESULTS

Among the 110 patients included in the study, those without anastomotic fistulas had a mean age of 54.13 years (median: 54 years), with a standard deviation of 5.10 years. Patients who developed anastomotic fistulas had a higher mean age of 59.71 years (median: 58 years) and a larger standard deviation of 9.88 years. The t-test for the difference in means showed a statistically significant difference ($p < .001$) between the two groups. The mean difference was -5.58 years, with a standard error of 1.50 years.

Of the 42 female patients, 19 (45.24%) developed anastomotic fistulas, whereas 23 (54.76%) did not. Among the 68 male patients, 36 (52.94%) developed fistulas,

while 32 (47.06%) did not. The calculated odds ratio of 1.362 suggests a slightly higher risk for male patients; however, the 95% confidence intervals (0.629-2.947) include the value of 1, and Fisher's exact test ($p = 0.556$) indicates that the difference is not statistically significant.

Among the 43 smokers, 40 (93.02%) developed anastomotic fistulas, compared to only 15 cases (22.39%) among the 67 non-smokers. The odds ratio of 46.222 indicates a significantly increased risk of fistula development in smokers. The confidence intervals (95% CI: 12.518-170.680) and Fisher's exact test ($p < 0.001$) confirms statistical significance.

Regarding alcohol consumption, 33 of the 34 alcohol consumers (97.06%) developed fistulas, compared to only 22 cases (28.95%) among the 76 non-consumers. The odds ratio of 81 suggests an extremely high risk associated with alcohol consumption. Confidence intervals (95% CI: 10.425-629.371) and Fisher's exact test ($p < 0.001$) confirm the statistical significance.

Patients with smaller tumors (2 cm) developed anastomotic fistulas in only 26.09% of cases, compared to 94.44% of those with 4 cm tumors. The proportion of fistula development in intermediate-sized tumors (3 cm) was 45.59%. The chi-square test ($\chi^2 = 21.013$, $p < 0.001$) indicates a statistically significant association between tumor size and fistula occurrence.

The highest proportion of anastomotic fistulas was observed in patients with tumors located in the gastric mid-corporeal region, where 23 out of 38 patients (60.53%) developed fistulas. Subcardial tumors (Siewert III) were associated with a lower proportion of fistulas (37.93%). Junctional esophagogastric tumors (Siewert II), lower esophageal tumors (Siewert I), and mid-esophageal tumors exhibited similar fistula proportions (46.15%, 50%, and 50%, respectively). However, these differences were not statistically significant ($\chi^2 = 3.451$, $df = 4$, $p = 0.485$).

Patients with adenocarcinoma developed anastomotic fistulas in 53.49% of cases (46 out of 86), compared to 37.50% (9 out of 24) in those with squamous cell carcinoma. However, statistical analysis showed that the differences between histopathological types were not statistically significant ($\chi^2 = 1.919$, $p = 0.166$).

A progressive increase in the risk of anastomotic fistulas was observed with advancing TNM stage. No fistulas were detected in stage 1 patients, whereas the incidence was 35.71% in stage 2, 92.86% in stage 3, and 100% in stage 4. The significant association between TNM stage and fistula occurrence was confirmed ($\chi^2 = 38.286$, $p < 0.001$).

Among the 36 patients with arterial hypertension, 33 (91.67%) developed anastomotic fistulas, compared to only 22 out of 74 patients (29.73%) without hypertension. The odds ratio of 26 indicates an extremely high risk, confirmed by significant confidence intervals (7.209-93.768) and Fisher's exact test ($p < 0.001$).

Similarly, 14 out of 16 diabetic patients (87.50%) developed fistulas, compared to 41 out of 94 non-diabetic patients (43.62%). The odds ratio of 9.049 indicates an increased risk, with statistical significance ($p = 0.002$).

Preoperative radiotherapy was associated with a significantly increased risk of anastomotic fistulas, with an odds ratio of 3.514 ($p = 0.003$). In contrast, preoperative chemotherapy was associated with a slightly lower risk (OR = 0.588), but this difference was not statistically significant ($p =$

0.556).

Patients who developed anastomotic fistulas had significantly higher levels of serum creatinine (1.04 ± 0.15 mg/dL *vs.* 0.91 ± 0.14 mg/dL, $p < 0.001$), blood glucose (98.56 ± 25.65 mg/dL *vs.* 88.55 ± 13.70 mg/dL, $p = 0.012$), and lower levels of serum albumin (3.52 ± 0.17 g/dL *vs.* 3.72 ± 0.14 g/dL, $p < 0.001$). Furthermore, hemoglobin levels were significantly lower in patients who developed fistulas (10.49 ± 1.43 g/dL *vs.* 12.78 ± 0.45 g/dL, $p < 0.001$).

Patients with anastomotic fistulas had significantly lower body mass index (BMI) values compared to those without fistulas (22.77 ± 1.87 *vs.* 24.11 ± 1.42, $p < 0.001$), suggesting a relationship between lower BMI and an increased risk of fistula development (tab. I).

TABLE I.

Relationships between risk factors and the risk of fistula development

Risk Factor	No Fistula (Mean ± SD/%)	Fistula (Mean ± SD/%)	p-value
Age	54.13 ± 5.10 yrs.	59.71 ± 9.88 yrs.	< 0.001
Smoking	22.39%	93.02%	< 0.001
Alcohol Consumption	28.95%	97.06%	< 0.001
Tumor Size	2.0 cm (26.09%)	4.0 cm (94.44%)	< 0.001
TNM Stage	Stage 1 (0%)	Stage 4 (100%)	< 0.001
Hypertension	29.73%	91.67%	< 0.001
Diabetes Mellitus	43.62%	87.50%	0.002
Radiotherapy	37.88%	68.18%	0.003
Chemotherapy	61.54%	38.46%	0.556
Serum Creatinine	0.91 ± 0.14	1.04 ± 0.15	< 0.001
Blood Glucose	88.55 ± 13.70	98.56 ± 25.65	0.012
Serum Albumin	3.72 ± 0.14	3.52 ± 0.17	< 0.001
Hemoglobin	12.78 ± 0.45	10.49 ± 1.43	< 0.001
BMI	24.11 ± 1.42	22.77 ± 1.87	< 0.001

DISCUSSION

Anastomotic fistulas represent a major and frequent complication in gastroesophageal surgery, significantly impacting postoperative outcomes. In this study, the predominant localization of fistulas at the esophagojejunal anastomosis (61.82%) aligns with the existing literature, which reports a higher incidence in this segment due to technical complexity and vascularization challenges. Although esophagogastric fistulas (38.18%) were less frequent, they remain a significant cause of morbidity.

Contrast-enhanced CT scan was the primary diagnostic modality, used in 85.45% of cases, highlighting its role as the gold standard for detecting anastomotic fistulas due to its high sensitivity and specificity. The mean time to fistula onset was 7.44 days postoperatively, consistent with literature reports identifying this period as the critical window for fistula detection,

driven by inflammatory and scarring processes. The concentration of cases within the 7-8-day period suggests that mechanical tension and peak inflammatory responses contribute to anastomotic dehiscence at this stage (4, 5).

Advanced age was significantly associated with a higher risk of fistula formation, with affected patients having a mean age of 59.71 years compared to 54.13 years in the control group. Literature findings confirm that older patients are at greater risk due to slower tissue regeneration, multiple comorbidities, and reduced tissue resilience. These findings underscore the need for personalized management strategies in elderly patients, including optimized surgical techniques, closer postoperative monitoring, and targeted preventive measures (6, 7).

A slightly higher prevalence of fistulas was observed in male patients (52.94%) compared to female patients (45.24%). However, statistical analysis did not indicate a significant difference, suggesting that sex is not a major determinant of fistula formation (7).

The study found a strong association between smoking and anastomotic fistula formation, likely due to impaired wound healing, reduced tissue vascularization, collagen disruption, and increased inflammation and infection risk (8).

An even stronger correlation was observed with alcohol consumption, with an odds ratio of 81.000, emphasizing its detrimental effect on tissue regeneration. Alcohol consumption is known to inhibit angiogenesis, impair immune function, and exacerbate local inflammatory responses, thereby increasing the risk of fistula formation. These findings highlight the importance of preoperative cessation programs for smoking and alcohol consumption in high-risk patients (9).

A significant correlation was identified between tumor size and the risk of anastomotic fistulas. Larger tumors (>3 cm) were associated with higher fistula rates, likely due to vascular compromise, difficulty in achieving a tension-free anastomosis, and increased risk of dehiscence. In contrast, smaller tumors ($\leq$ 2 cm) had a significantly lower risk, reinforcing the hypothesis that tumor burden influences postoperative anastomotic integrity (10).

While gastric mid-body tumors (60.53%) were associated with a higher proportion of fistulas, statistical analysis did not identify a significant correlation between tumor location and fistula formation. Similarly, although adenocarcinoma (53.49%) had a higher rate of anastomotic fistulas than squamous cell carcinoma (37.50%), the difference was not statistically significant, suggesting that histopathology was not a decisive factor in fistula development in this cohort (11).

A progressive increase in fistula risk was observed with advancing TNM stage, with significant associations across T, N, and M components (12).

- T3-T4 tumors were associated with higher fistula rates, reflecting extensive local invasion and compromised tissue integrity, consistent with literature indicating that advanced local tumors increase anastomotic failure risk.
- All patients with distant metastases (M1) developed anastomotic fistulas, suggesting that systemic disease burden and poor overall physiological status contribute to impaired wound healing. These findings emphasize the importance of accurate preoperative staging and multidisciplinary interventions, including nutritional support

and perioperative optimization, to mitigate complication rates in advanced-stage patients.

A strong correlation was observed between hypertension and anastomotic fistula formation, indicating that compromised microvascular circulation and increased anastomotic tension may contribute to dehiscence (13,14).

Similarly, diabetes mellitus was associated with a higher fistula risk, likely due to microvascular dysfunction, chronic inflammation, and delayed wound healing. Given that diabetic patients are more prone to infections, strict perioperative glycemic control and wound surveillance are essential in reducing complications.

Preoperative radiotherapy was significantly associated with an increased risk of anastomotic fistulas, likely due to vascular damage and impaired tissue healing. Literature findings confirm that high radiation doses can compromise anastomotic integrity, particularly in advanced tumors (15).

In contrast, preoperative chemotherapy was not significantly associated with an increased fistula risk, suggesting that its impact on anastomotic healing is less pronounced than that of radiotherapy.

Altered biological parameters at hospital admission were strongly correlated with fistula development.

- Increased serum creatinine levels indicate renal dysfunction, which may impair tissue regeneration and stress response management.
- Hyperglycemia was associated with a higher risk of fistula formation, emphasizing the need for strict perioperative glucose control.
- Hypoalbuminemia, indicative of malnutrition, was a strong predictor of postoperative complications, reinforcing the importance of preoperative nutritional optimization.
- Anemia, reflected by lower hemoglobin levels, suggested tissue hypoxia and impaired healing capacity, highlighting the need for preoperative hematologic correction.

Patients with a lower BMI were more prone to anastomotic fistulas, likely due to malnutrition, reduced muscle mass, and lower energy reserves, all of which negatively impact wound healing. These findings emphasize the importance of preoperative nutritional assessment and correction, particularly in underweight patients. Nutritional interventions, including protein supplementation and enteral/parenteral support, may help reduce the risk of anastomotic fistulas and improve postoperative outcomes.

CONCLUSIONS

This study identifies multiple risk factors associated with the development of anastomotic fistulas after esophageal and gastric cancer surgery. Advanced age, smoking, alcohol consumption, large tumor size, advanced TNM stage, hypertension, diabetes, hypoalbuminemia, anemia, and preoperative radiotherapy were all strongly correlated with an increased risk of fistula formation. Understanding these risk factors is essential for identifying high-risk patients and implementing targeted perioperative interventions to improve surgical outcomes.

CONFLICT OF INTEREST AND FUNDING

The authors declare no conflicts of interests. The research did not receive external funding.

NAVIGATING THE PRESSURES: ADDRESSING OCCUPATIONAL STRESS AND BURNOUT AMONG ANESTHESIOLOGISTS AND ICU PROFESSIONALS (Abstract): Occupational stress and burnout have become critical issues in healthcare, particularly among anesthesiologists and Intensive Care Unit (ICU) professionals. By addressing these issues, we aim to foster a healthier work environment that can sustain the vital contributions of anesthesiologists and ICU personnel. **Materials and methods:** A cross-sectional survey was conducted among 49 anesthesiologists and intensive care unit (ICU) physicians working in several hospitals in the City of Iași, Romania. The survey included the *Perceived Stress Scale* (PSS), the *Maslach Burnout Inventory* (MBI), and additional demographic questions regarding job seniority, age, sex, and marital or long-term partnership status. **Results:** underscores the central role of stress management in preventing emotional exhaustion. Although the regression did not identify age, sex, or marital status as statistically significant predictors, the data trends still point to meaningful subgroup differences. These results align with previous research emphasizing the psychological toll of sustained high-pressure clinical environments where women may be more prone to emotional exhaustion, and younger male professionals may face higher risks of depersonalization. **Conclusions:** This study underlines the need for targeted interventions aimed at managing perceived stress as a method of preventing professional burnout. Promoting mental health, work-life balance, and organizational support should become institutional priorities, especially in critical areas such as anesthesia and intensive care. **Keywords**: OCCUPATIONAL STRESS, BURNOUT, ANESTHESIOLOGISTS.

INTRODUCTION

Occupational stress and burnout have become critical issues in healthcare, particularly among anesthesiologists and Intensive Care Unit (ICU) professionals. These highly specialized fields demand not only extensive knowledge and technical proficiency but also the capacity to perform under intense pressure, often with life-or-death consequences. The unique challenges faced by anesthesiologists and ICU workers, such as long hours, high patient acuity, and the emotional toll of critical care, contribute significantly to their stress levels (1, 2).

In recent years, the conversation around mental health in the medical community has gained momentum, revealing alarming rates of burnout among healthcare providers (3).

For anesthesiologists and ICU staff, the combination of high-stakes environments and constant vigilance can lead to chronic stress and burnout, adversely affecting their well-being and potentially compromising patient care (4, 5). Understanding the factors that contribute to occupational stress and identifying strategies to mitigate burnout are essential for ensuring the health and effectiveness of these crucial healthcare workers.

This article delves into the root causes of occupational stress and burnout among anesthesiologists and ICU professionals. It examines the psychological and physical demands of their roles, explores the impact of workplace stressors, and discusses evidence-based interventions to support their mental health. By addressing these issues, we aim to foster a healthier work environment that can sustain the vital contributions of anesthesiologists and ICU personnel.

FACTORS CONTRIBUTING TO OCCUPATIONAL STRESS AND BURNOUT

1. High workload and long hours:

Anesthesiologists: Often work long shifts and are on call for emergencies. The nature of their job requires constant vigilance and precision (6).

ICU Physicians: Manage critically ill patients, which involves complex decision-making, frequent emergencies, and long hours (7).

2. Emotional demands:

Both specialties deal with life-and-death situations regularly, leading to emotional exhaustion (1).

Interactions with patients' families during critical times add to emotional stress (8).

3. High responsibility and risks

Anesthesiologists and ICU doctors are responsible for patients during critical phases, where errors can have severe consequences (5).

The need to stay updated with medical advancements and protocols increases mental load (9).

4. Working environment

The ICU is a high-stress environment with alarms, equipment, and constant activity (6).

Operating rooms for anesthesiologists are high-pressure settings, requiring intense concentration (7).

5. Administrative and bureaucratic pressures

Documentation, compliance with regulations, and administrative duties add to the workload (10).

Managing insurance and patient care coordination can be burdensome (11).

MATERIALS AND METHODS

Study Design

A cross-sectional survey was conducted among anesthesiologists and intensive care unit (ICU) physicians working in several hospitals in the city of Iași. The survey included the *Perceived Stress Scale* (PSS), the *Maslach Burnout Inventory* (MBI), and additional demographic questions regarding job seniority, age, sex, and marital or long-term partnership status (12-14). In Romania, anesthesiologists also manage intensive care. For simplicity, the term anesthesiologist is used throughout this article (15).

Data Collection

Data were collected through a printed questionnaire distributed over a three-week period. Participation was voluntary, and responses were anonymized to ensure confidentiality. Ethical approval for this study was obtained from the Research Ethics

Committee of "Grigore T. Popa" University of Medicine and Pharmacy of Iași (Approval No. 438/28.04.2024).

Scales and inventories

Perceived Stress Scale (PSS): A widely used psychological instrument for measuring the perception of stress. Originally developed in 1983, it remains a valid and reliable tool to assess how different situations affect personal feelings and stress perception over the past month (10).

Maslach Burnout Inventory (MBI): This tool assesses three core dimensions of burnout:

- Emotional Exhaustion (feeling emotionally drained and fatigued),
- Depersonalization (developing a detached or cynical attitude toward patients),
- Personal Accomplishment (feelings of competence and successful achievement at work) (1).

RESULTS

Data from 49 respondents who completed the Perceived Stress Scale (PSS) and the Maslach Burnout Inventory (MBI) were analyzed. The purpose of the analysis was to identify statistically significant differences between demographic subgroups and to determine the predictors of emotional exhaustion.

Descriptive Statistics

- Average age: 40.2 years (range: 28-63)
- PSS Score (perceived stress): mean = 20.1, range = 4-35
- Emotional Exhaustion (MBI-EE): mean = 24.8, range = 6-50
- Depersonalization (MBI-DP): mean = 10.9, range = 0-26
- Personal Accomplishment (MBI-PA): mean = 25.2, range = 10-41

Differences in Perceived Stress Between Sexes

The independent t-test for PSS scores between men and women showed no statistically significant difference: $t(47) = -0.88$, $p = 0.39$. Thus, no significant difference was found in perceived stress levels between sexes.

Differences in Emotional Exhaustion Across Age Groups

The ANOVA test indicated a trend toward statistical significance between age groups in emotional exhaustion scores: $F(2, 46) = 2.44$, $p = 0.098$. Although not significant at $p < 0.05$, this result suggests a possible age-related influence that warrants further exploration in larger samples.

Correlation Between Age and Depersonalization

The Pearson correlation coefficient between age and depersonalization score was $r = -0.028$, $p = 0.85$, indicating no significant relationship.

Multiple Regression: Predicting Emotional Exhaustion

The linear regression model included the following predictors: age, sex, PSS score, and marital status. Results showed that the only statistically significant predictor of emotional exhaustion was the PSS score ($p < 0.001$). Sex, age, and marital status did not have a significant influence in the model. This suggests that perceived stress is a key determinant of emotional burnout.

This finding underscores the central role of stress management in preventing

emotional exhaustion. Although the regression did not identify age, sex, or marital status as statistically significant predictors, the data trends still point to meaningful subgroup differences worth exploring in future research.

The findings of this study indicate that perceived stress is the primary factor associated with emotional exhaustion, the core dimension of burnout. Although no statistically significant differences were identified between sexes or age groups regarding PSS or MBI scores, observed trends suggest that women tend to score higher on emotional exhaustion, while younger male physicians are more at risk for depersonalization.

These results align with existing literature that highlights increased vulnerability among younger or overburdened healthcare personnel (2, 3).

The lack of influence of marital status corroborates other studies suggesting that emotional balance is not necessarily determined by this factor, but rather by effective social support and individual coping strategies (13).

DISCUSSION

The findings of this study confirm the relevance of perceived stress as a key driver of emotional exhaustion in anesthesiologists and intensive care professionals. Although no statistically significant differences were observed between sexes or age groups in the Perceived Stress Scale (PSS) or Maslach Burnout Inventory (MBI) scores, the analysis showed a strong association between perceived stress and emotional burnout, as evidenced by the regression model where PSS emerged as the only significant predictor ($p < 0.001$).

These results align with previous research emphasizing the psychological toll of sustained high-pressure clinical environments (2)(3). While the t-test and ANOVA did not reveal statistically significant group differences, the observed trends suggest that women may be more prone to emotional exhaustion, and younger male professionals may face higher risks of depersonalization. These trends are consistent with studies reporting increased burnout vulnerability among early-career physicians and female healthcare workers balancing professional and social expectations (4)(5).

The absence of a statistically significant correlation between age and depersonalization ($r = -0.028$, $p = 0.85$) indicates that emotional distancing may not necessarily be a function of age, but perhaps of work-related coping strategies or organizational culture. Similarly, marital or partnership status showed no predictive power in the regression analysis, suggesting that emotional resilience may be more influenced by individual or systemic factors rather than personal relationships (13).

Taken together, these findings support the need for targeted interventions focused not only on reducing work-related stress but also on promoting psychological resources and institutional safeguards. Burnout prevention should become a core component of workforce well-being programs, especially in specialties where clinical intensity and emotional demand are persistently high.

CONCLUSIONS

The analysis highlights that although there are no statistically significant differences between sexes or age groups regarding PSS and MBI scores, perceived stress remains a major predictor of emotional exhaustion.

This study underlines the need for targeted interventions aimed at managing perceived stress as a method of preventing professional burnout. Promoting mental health, work-life balance, and organizational support should become institutional priorities, especially in critical areas such as anesthesia and intensive care. Future studies should include larger samples and longitudinal analyses to track the progression of burnout over time.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

STUDY ON THE IMPACT OF DIODE LASER ON POSTOPERATIVE EVOLUTION IN ORAL SURGERY (Abstract): **Aim of study** was to compare the clinical postoperative evolution in the treatment of gingival hyperplasia by using diode laser and scalpel surgery. **Materials and methods**: A total of 40 patients with gingival hyperplasia, selected from the Clinical Learning Base of the Faculty of Dental Medicine, Grigore T. Popa University of Medicine and Pharmacy Iasi, were included in study. Participants were divided in test group (laser-assisted surgery, n = 20) and control group (scalpel surgery, n = 20). The laser surgery was performed with Epic (BioLase) (940 nm). Postoperative evolution was assessed at 24 hours, 3 days, and 7 days. The postoperative evolution was assessed by the progression of the postoperative pain intensity (Visual Analogue Scale) and healing time (days). **Results:** For gingivectomy performed with diode laser, mean VAS scores decreased from 2.60 ± 0.38 days at 24 h to 0.21 ± 0.22 at 7 days ($p < 0.001$) versus 5.20 ± 0.77 days (at 24 h) to 1.20 ± 0.64 (7 days) in the scalpel group ($p < 0.001$). Mean healing times were significantly shorter after laser therapy (3.20 ± 0.77 days) compared to scalpel surgery (8.40 ± 2.09). **Conclusions:** Laser-assisted surgery lead to faster healing time and accelerates the decrease of postoperative pain intensity during first 7 days posttreatment, compared to traditional surgical approach. **Keywords:** LASER, DIODE, GINGIVECTOMY, VAS, HEALING.

INTRODUCTION

The laser has become increasingly integrated into fields such as science, communications, astronomy, engineering, and medicine. A laser can be defined as a device that produces light energy through an optical amplification process, according to the stimulated emission of electromagnetic radiation (1). The benefits of lasers in oral surgery include the absence of harmful heat to oral tissues, bacteriostatic and bactericidal action, reduced bleeding time and elimination of the suturing of the postoperative wound (2, 3). The active component of this common dental laser is a solid-state semiconductor made from aluminum and gallium, emitting an optical wavelength generally ranging from 810 to 980 nm (4, 5). Diode laser combine ablative action with biostimulant effect (6-8). Localized biostimulator with diode lasers increases the release of endorphins and reduces the activity of inflammatory mediators up to a depth of 1 cm, while also facilitating cellular replication and thus promoting bone growth (9, 10). Localized biostimulation with diode lasers increases the release of endorphins and reduces the activity of inflammatory mediators

up to a depth of 1 cm, while also facilitating cellular replication and thus promoting bone growth (9). Diode lasers reduce the use of anesthesia required for the surgical procedures leading to greater patient compliance with less discomfort, improved overall acceptance of the procedure (10). Low-Level Laser Therapy (LLLT), also known as "soft laser therapy," has been used in medicine for over three decades. Low-level lasers emit short-wavelength red or infrared light which can penetrate to a depth of 3 mm to 15 mm in both soft and hard tissues (11, 12). LLLT can influence inflammatory processes and reduce acute inflammatory pain by decreasing, in a dose-dependent manner, levels of prostaglandin E2, IL1-beta, TNF-alpha, oxidative stress, edema, and by reducing the frequency of nociceptor activation in peripheral nerve signals (13). LLLT facilitates wound healing by accelerating fibroblast proliferation, ATP synthesis, and collagen synthesis (14-17). Laser and LED light induce a PBM effect used to accelerate healing by increasing cell viability through the stimulation of ATP synthesis in mitochondria and cell membrane photoreceptors (18-20).

The aim of this study was to compare the evolution of the clinical postoperative parameters between patients treated by diode laser-assisted and patients treated by conventional (scalpel) surgery in the treatment of gingival hyperplasia.

MATERIALS AND METHODS

In this prospective study, 40 patients (28 males; 22 females; mean age 42.5 ± 12; range 20-65 years) were selected from Clinical Base "Kogalniceanu M" of Dental Medicine Faculty, Grigore T. Popa University of Medicine and Pharmacy Iasi. The research was performed according to Code of Ethics of the World Medical Association regarding the studies performed on human subjects. Before entering in study, the patients signed a written consent. The inclusion and exclusion criteria for patients included in study are presented further.

Inclusion criteria: anterior region; age between 18-50 years; plaque-induced inflammatory gingival hyperplasia; orthodontic treatments with gingival hyperplasia; systemically healthy patients.

Exclusion criteria: gingival enlargement due to systemic predisposing factors; pregnancy and/or lactation; systemic diseases requiring antibiotic prophylaxis and/or anti-inflammatory medications; acute or untreated periodontal disease; diabetes.

The diode laser surgical procedures were used in test group (n=20). The conventional surgical procedures (scalpel) were used in control group (n=20). The parameters of diode laser EPIC (BioLase, USA) (940 nm) were as follows: 1W, pulse mode, contact, 300 µm fiber; LLLT: 0,2W power, 35J/cm^2). The results were compared with control group (n=20).

The postoperative evolution was assessed by using VAS (Visual Analogue Scale) indices and healing time (days). These parameters were recorded at 24 hours, 3 days and 7 days. VAS indices were measured by a scale from 0 to 100, where 0 indicates absent pain and 100 indicates the most severe pain. Each patient was asked to select the score that represented the pain experienced at the time of evaluation (24 hours, 3 days, and 7 days postoperatively). The chosen value was recorded as the patient's VAS score. The pain intensity was set according to VAS scores: 0-1 (no pain); 2-3 (mild pain); 4-6 (moderate pain). Healing time was considered when patients perceives the treated

gingival area as "healed," with minimal discomfort

Statistical analysis. Descriptive and analytical statistics were applied. The mean, standard deviation (SD), median was used to describe numerical data. The frequency and proportion of nominal data were presented; the comparison between categorial variables were made using the Chi-squared test. The variables to analyze were checked against the normal distribution using the Kolmogorov-Smirnov Test. Mann-Whitney test was used to compare them between the two groups, and Friedman test was used to compare outcome data within each group. Statistical significance was defined as a p-value less than or equal to 0.05. *SPSS version 29.0* was used to conduct all statistical analyses (Chicago, IL, USA Inc.).

RESULTS

At 24 hours, the laser group showed much lower pain scores (mean 2.60 ± 0.38) compared with the scalpel group (mean 5.20 ± 0.77), with a highly significant difference ($p < 0.001$). After 3 days, the laser group again reported reduced pain (mean 1.20 ± 0.39) relative to the scalpel group (mean 4.40 ± 0.77) ($p < 0.001$). At 7 days, pain in the laser group was minimal (mean 0.21 ± 0.22), while the scalpel group still showed notable discomfort (mean 1.20 ± 0.64), with the significant statistical difference ($p < 0.001$). For both techniques, pain decreased significantly over time ($p < 0.001$) (tab. I).

TABLE I.

Postoperative pain intensity evolution (laser *vs*, scalpel)

VAS	Laser		Scalpel		Mann-Whitney Test p-value
	Mean ± SD	Median (IQR)	Mean ± SD	Median (IQR)	
24 h	2.60 ± 0.385	2.57 (2.34 ÷ 2.89)	5.20 ± 0.767	5.15 (4.68 ÷ 5.76)	< 0.001**
3 days	1.20 ± 0.387	1.21 (0.85 ÷ 1.39)	4.40 ± 0.774	4.41 (3.71 ÷ 4.78)	< 0.001**
7 days	0.21 ± 0.224	0.16 (0.00 ÷0.44)	1.20 ± 0.636	1.24 (0.71÷ 1.78)	< 0.001**
Friedman test	p < 0.001**		p < 0.001**		

At 24 hours, most patients in the laser group reported only mild pain (90.0%), with 10.0% having no pain at all. In contrast, the scalpel group showed predominantly moderate pain (90.0%), and only 10.0% reported mild pain. The difference between groups was highly significant ($p < 0.001$). After 3 days, 95.0% of patients in the laser group reported no pain, while the scalpel group continued to show higher discomfort levels, with 70.0% experiencing moderate pain and 30.0% mild pain ($p < 0.001$). At 7 days, all patients in the laser group were pain-free (100.0%), compared with 90.0% in the scalpel group; 10.0% of scalpel cases still reported mild pain. At 7 days, the difference between groups was not significant ($p = 0.487$) (tab. II).

The laser group healed in an average of 3.20 ± 0.77 days (median 3.00), while the scalpel group required 8.40 ± 2.09 days on average (median 9.00). The difference between the two surgical techniques was highly significant ($p < 0.001$) (tab. III).

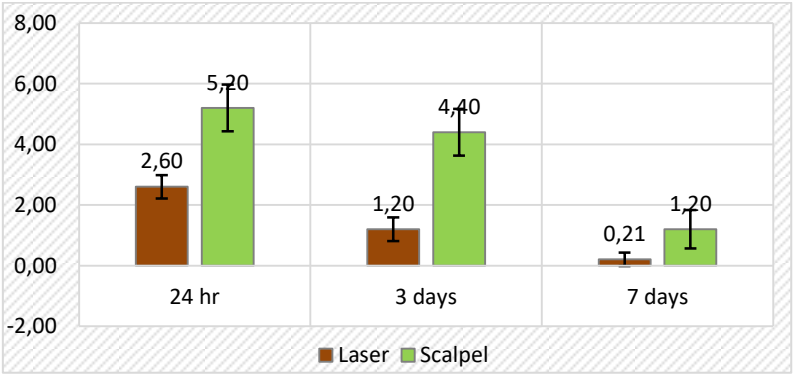

Fig. 1. Mean VAS indices at 24hr, 3 days, 7 days (laser vs scalpel)

TABLE II.

The qualitative study of postoperative pain intensity

VAS		Group				Total		Pearson Chi-squared p-value
		Laser		Scalpel				
		N	%	N	%	N	%	
24 hrs.	no pain	2	10.0%			2	05.0%	< 0.001**
	mild pain	18	90.0%	2	10.0%	20	50.0%	
	moderate pain			18	90.0%	18	45.0%	
3 days	no pain	19	95.0%			19	47.5%	< 0.001**

TABLE III.
Healing time within the tested samples

	Laser		Scalpel		Mann-Whitney Test p-value
	Mean ± SD	Median (IQR)	Mean ± SD	Median (IQR)	
Healing days	3.20 ± 0.768	3.00 (3.00 ÷ 3.00)	8.40 ± 2.088	9.00 (6.00 ÷ 9.75)	< 0.001**

DISCUSSION

Pre-prosthetic surgical procedures are required to optimize the prosthetic field in complex oral rehabilitation. Surgical interventions using scalpel are considered gold standard technique due to its ease of use and economic benefits. However, surgical lasers have the advantage of precision, patient comfort, and faster healing (21, 22). Gingivectomies are among the surgical procedures that can benefit significantly from the use of diode laser (23).

Our study demonstrates the clinical advantages of laser-assisted soft tissue surgery such as gingivectomy and frenectomy when compared with scalpel techniques. Our results in diode laser-assisted gingivectomy align with current literature (23, 24). In gingivectomy, diode laser use resulted in minimal discomfort from the first postoperative day (VAS 2.6), with a rapid decline by day 3 (VAS 1.2) and near-complete resolution by day 7 (VAS 0.6). Patients submitted to scalpel surgery had significantly higher VAS indices at each corresponding interval. Diode laser gingivectomy required a mean of only 3.2 days for satisfactory clinical healing, while traditional scalpel procedures required significantly more time (8.4 days). These differences may be explained by the reduced tissue trauma, improved coagulation, and decreased postoperative inflammation associated with laser interaction (25). In laser group, clinical functional healing represents a rapid and almost complete epithelial recovery, while deeper tissue healing is histologically incomplete but clinically favorable. The absence of mechanical damage and minimal thermal spread in diode laser assisted surgery favorize the recontouring of the soft tissues with the precision of a scalpel.

Complete gingival remodeling occurs in the next 2-3 weeks, while the final stabilization of the gingival contour is achieved within 4-6 weeks (1, 24).

In our study the ablation stage was followed by low-level laser therapy. LLLT favors the additional decrease of postoperative pain intensity and healing time according to research groups (26-28). A systematic review evaluated the effect of LLLT as an adjunct to periodontal surgery in the management of postoperative pain and healing time. It was reported a significant decrease in the mean analgesic intake during the first week in the LLLT group ($\leq$ 500 mW, $\geq$ 5 J/cm^2) when compared with control (29).

These results add to the increasing body of evidence that diode laser gingivectomy not only provides clinical benefits in terms of postoperative comfort and healing times, but also in terms of patient satisfaction. The shorter healing times and lower pain scores in laser groups have implications for patients' quality of life, leading to earlier return to normal activities, reduced intake of analgesics and fewer postoperative complications. Shorter recovery and less pain can be clinically significant in terms of patient compliance, particularly when the dental treatment plans are of

multiple stages such as periodontal or prosthetic treatments.

The limited management of postoperative cases is correlated to less need for periodontal dressing and reduced hemorrhage.

In addition, finite soft tissue ablation with low collateral damage could contribute to the earlier healing profile as observed in our study.

However, histological and immunohistochemical analysis showed no significant differences regarding inflammatory cell infiltrate in laser-treated tissues compared with scalpel surgical procedures (30, 31).

Despite specific training and higher initial investment required for diode lasers, the clinical benefits encourage their use in oral surgery (32).

CONCLUSIONS

Oral surgery performed with diode laser (940 nm) resulted in significantly lower postoperative pain compared with the scalpel technique. The diode laser offered reduced discomfort at 24 hours and 3 days, along with a markedly shorter healing period than the conventional surgical approach.

LONGITUDINAL ANALYSIS OF MATERNAL AND CHILD HEALTH INDICATORS IN BACĂU COUNTY, ROMANIA (2021-2024) (Abstract): This longitudinal observational study assessed the evolution of maternal and child health indicators in Bacau County, Romania, between 2021 and 2024, using annual administrative data collected from hospitals and medical practices involved in maternal and child health services. **Materials and methods**: The analysis focused on service coverage, year-to-year variations, and discontinuities in key program-related interventions. Descriptive statistical analyses were performed using SPSS version 28 and Microsoft Excel. **Results**: During the study period, improvements were observed in several components, particularly neonatal screening activities and nutritional support for low-birth-weight newborns. Coverage of Rh immunological prophylaxis among Rh-negative pregnant women increased alongside better orientation of services toward vulnerable population groups. Nevertheless, persistent challenges were identified in postnatal follow-up of preterm infants and in ensuring equitable access to infant formula. Additionally, a declining birth rate was noted, with potential implications for resource allocation and service planning. Overall, the findings indicate heterogeneous longitudinal trends in maternal and child health indicators, reflecting variable continuity and performance across service components. **Conclusions:** These results underline the need for targeted adjustments to enhance the consistency and quality of maternal and child health interventions at the local level. **Keywords**: MATERNAL HEALTH, CHILD HEALTH, LONGITUDINAL ANALYSIS, HEALTH INDICATORS, ROMANIA.

INTRODUCTION

The promotion and protection of women's and children's health represent a core public health priority at both national and international levels. These population groups require continuous, targeted interventions to ensure equitable access to healthcare services, prevent disease, and support healthy growth and development. Maternal and child health programmes contribute directly to reducing maternal and infant mortality, preventing chronic conditions, promoting family planning, and improving overall population health outcomes (1-4).

The COVID-19 pandemic exerted additional pressure on healthcare systems in Romania, revealing pre-existing structural vulnerabilities and emphasizing the importance of realistic assessments of public health programme implementation. In this context, maternal and child health interven-

tions have remained essential for addressing health inequalities and maintaining continuity of preventive and curative services. Such interventions typically follow a hierarchical approach, prioritizing primary prevention and health education, followed by early diagnosis and timely treatment, in line with international maternal and child health frameworks (5-8).

Evidence from the literature indicates that the implementation of maternal and child health programmes is frequently uneven, particularly in rural areas and among vulnerable population groups, where access to healthcare services remains limited (9). In Romania, inconsistencies in neonatal screening coverage and in the application of nutritional and immunological protocols have been reported, resulting in notable gaps when compared with European benchmarks (10-12). Urban-rural disparities, shortages of healthcare professionals, and infrastructural constraints further affect the effectiveness and equity of service delivery (13). These challenges underline the need for coordinated action among family physicians, hospital-based services, public health authorities, and community-level actors to ensure continuity and coherence of care.

At the strategic level, maternal and child health priorities in Romania are aligned with World Health Organization (WHO) recommendations and are embedded in national policy frameworks, including the National Health Strategy, the National Strategy on Equal Opportunities and Treatment between Women and Men (2022-2027), the National Cancer Control Plan, and the National Mental Health Strategy (14,15). Core objectives include reducing maternal and infant mortality, promoting reproductive health and family planning, monitoring child development, and addressing inequalities in access to health services (16-18). Within this framework, longitudinal analyses at the local level are essential for understanding temporal trends and identifying areas requiring improvement.

This study was motivated by the need to assess the performance and continuity of maternal and child health interventions in settings characterized by increased population vulnerability. In the context of disruptions generated by the COVID-19 pandemic and the subsequent recovery of the Romanian healthcare system, evaluating the local implementation of key maternal and child health components provides relevant insight into system resilience and service delivery at the county level.

The aim of this research was to conduct a longitudinal analysis of maternal and child health indicators in Bacău County over the period 2021-2024, using administrative data associated with program-related services. The specific objectives were to evaluate temporal changes in service coverage, to identify discontinuities or functional challenges across major intervention components, and to analyze trends in the number of beneficiaries by subcomponent in order to describe population coverage patterns during the study period.

MATERIALS AND METHODS

A longitudinal observational study was conducted to assess maternal and child health indicators associated with the implementation of program-related services in Bacău County, Romania. The analysis covered the period 2021-2024 and included data from three public hospitals-Bacău

County Emergency Hospital, Moinești Municipal Emergency Hospital, and St. Hierarch Dr. Luca Onești Municipal Hospital-as well as from 11 family medicine practices involved in maternal and child health service delivery at the county level.

All medical units participating in the implementation of maternal and child health interventions during the study period were considered eligible for inclusion. No exclusion criteria were applied, and all validated data available from the participating institutions were included in the analysis.

Data was collected through document review of primary and secondary sources, including official reports and datasets provided by the participating hospitals, maternal and child health statistics obtained from the healthcare units included in the study, legislative acts, national strategic documents, and databases of the National Institute of Public Health (INSP). The main variables of interest included the number of beneficiaries by intervention component, annual variations, coverage rates, and indicators of discontinuity in service provision. Calculated measures comprised absolute numbers of beneficiaries, base indices, and dynamic chain indices expressed as percentages.

Statistical analysis was descriptive reflecting the observational design of the study. Descriptive statistics, including absolute values, means, and frequencies, were generated using IBM *SPSS Statistics version 28* and *Microsoft Excel*. Comparative analyses were performed to describe temporal dynamics over the 2021-2024 period, while qualitative information from official documents was interpreted using thematic analysis. This approach allowed the identification of major longitudinal trends, urban-rural differences, and contextual factors influencing service continuity and performance.

The study was conducted in accordance with applicable legislation and ethical standards, following the Standards of Research Ethics in Medical Sciences (19) and the principles of the Declaration of Helsinki (20). Ethical approval was obtained from the Ethics Committees of Bacău County Emergency Hospital (Decision No. 30695/28.12.2022), Moinești Municipal Emergency Hospital (07.12.2022), and St. Hierarch Dr. Luca Onești Municipal Hospital (Decision No. 21613/23.12.2022), as well as from the Ethics Committee of the Grigore T. Popa University of Medicine and Pharmacy Iași (Decision No. 255/17.01.2023). The study forms part of a doctoral research project conducted at the Doctoral School of the Grigore T. Popa University of Medicine and Pharmacy Iași (Doctoral contract No. 1916 / 29.10.2021),

RESULTS

The application of maternal and child health program-related services in Bacău County generated relevant findings regarding population coverage and the longitudinal evolution of key maternal and child health indicators. The analysis highlighted heterogeneous temporal trends across intervention components, reflecting both improvements in service delivery and the persistence of discontinuities during the study period. These results provide a descriptive overview of program performance at the county level between 2021 and 2024.

Number of newborns

The number of newborns recorded in hospitals across Bacău County showed a continuous decline over the 2021-2024

period. Compared with the baseline year 2021, the total number of live births decreased by approximately 30% by 2024. As shown in (*tab. I*), the number of newborns declined from 5,961 in 2021 to 5,819 in 2022 (97.6% of the baseline), followed by a marked reduction to 4,466 in 2023 (74.9%) and a further decrease to 4,148 in 2024 (69.6%). The most pronounced decrease occurred between 2022 and 2023, while the reduction observed between 2023 and 2024 was more moderate.

Preterm births

The evolution of preterm births recorded in hospitals across Bacău County showed a fluctuating pattern during the 2021-2024 period (fig. 1). Between 2021 and 2023, the number of preterm births decreased by approximately 30%, followed by an increase of about 13% in 2024 compared with the previous year. Overall, the data indicates a non-linear temporal trend, characterized by a decline during the first part of the study period and a subsequent increase in the final year.

TABLE I.

Number of newborns in hospitals in Bacau county (2021-2024)

(Source: Hospital administrative data, National Health Program PN XIII, 2021-2024)

Year	Number of newborns	Dynamic base indices (%)
2021	5.961	100.0
2022	5.819	97.6
2023	4.466	74.9
2024	4.148	69.6

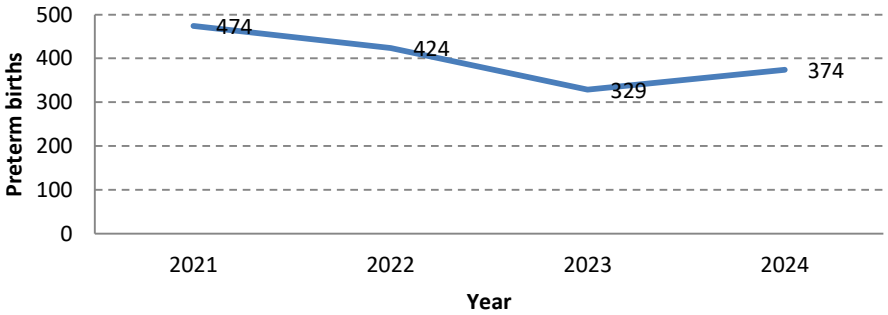

Fig. 1. Preterm births in Bacău County, 2021-2024.

Prevention of hearing loss through newborn screening

Coverage of newborn hearing screening increased substantially between 2021 and 2024, rising from 45.03% to 74.61%, which represents a relative increase of 65.7% compared with the baseline year (fig. 2). The upward trend was consistent throughout the study period and was most pronounced in 2024.

The absolute number of newborns screened for hearing loss varied year to year. In 2022, an increase of 10.39% compared with 2021 was observed, followed by a decrease of 15.22% in 2023. In 2024, the number of screened newborns increased by 39.65% compared with 2023, representing the highest value recorded during the study period.

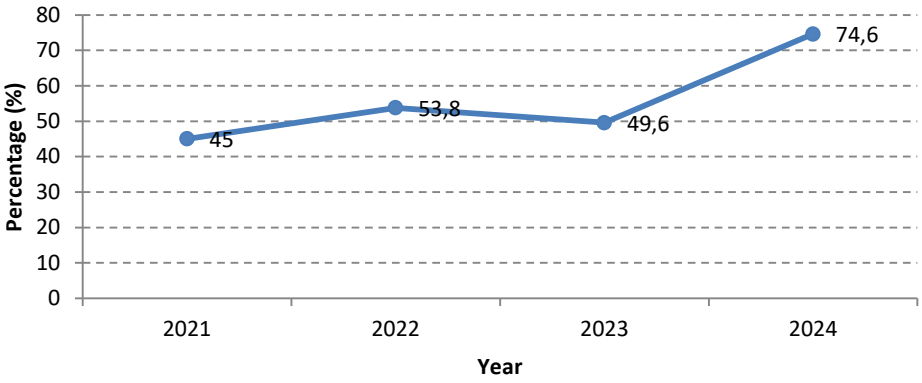

Fig. 2. Hearing loss screening coverage in Bacău County, 2021-2024.

Prevention of retinopathy of prematurity

Between 2021 and 2024, the coverage rate of screening for retinopathy of prematurity increased from 86.05% to 100% and remained at this level during the final years of the study period. Over the same interval, the number of preterm newborns eligible for screening increased from 86 cases in 2021 to 127 cases in 2024, with a corresponding increase in the number of beneficiaries, resulting in complete screening coverage during 2022-2024.

In contrast, the proportion of preterm newborns monitored after initial screening decreased progressively over the study period, declining from 93.02% in 2021 to 70.08% in 2024, indicating variability in continuity of post-screening follow-up.

Malnutrition prophylaxis in infants aged 0-12 months without access to breast milk

During the 2021-2024 period, the proportion of infants aged 0-12 months benefiting from malnutrition prophylaxis through infant formula decreased from 4.38% to 2.60%. In absolute terms, the number of beneficiaries declined from 232 cases in 2021 to 127 cases in 2024 (fig. 3). This reduction occurred gradually over the study period, in parallel with the decrease in the number of live births.

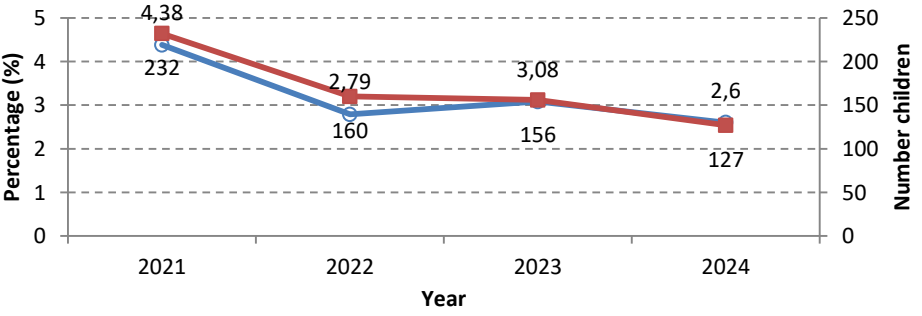

Fig. 3. Number and proportion of infants aged 0-12 months receiving malnutrition prophylaxis with infant formula in Bacău County, 2021-2024.

Malnutrition prophylaxis in low-birth-weight infants

Among low-birth-weight infants, the proportion of beneficiaries receiving nutritional prophylaxis increased from 83.92% in 2021 to 95.89% in 2024, in the context of a relatively stable number of eligible cases. This finding reflects a progressive increase in coverage over the study period.

Prophylaxis of Rh isoimmunization syndrome

Coverage with anti-D immunoglobulin among Rh-negative pregnant women showed moderate variation between 2021 and 2024. Coverage increased to 75.40% in 2023, followed by a decrease to 70.45% in 2024. The absolute number of beneficiaries followed a similar pattern, reaching a peak of 233 cases in 2023 and decreasing to 217 cases in 2024.

DISCUSSION

The findings of this longitudinal analysis indicate a heterogeneous pattern of performance across maternal and child health services at the county level. While several core interventions showed measurable improvement during the study period, persistent discontinuities and inequalities pointed to an ongoing gap between regulatory frameworks and their consistent operationalization. This pattern is consistent with the concept of the "implementation gap" described in public health literature, referring to the discrepancy between formally established policies and their effective translation into routine practice (15).

A clear illustration of this gap is provided by the prophylaxis of Rh isoimmunization through the administration of anti-D immunoglobulin. Although this intervention is well regulated and standardized at the national level, the observed variability in coverage suggests vulnerabilities in supply chains, reporting mechanisms, and service coordination. Similar challenges have been reported in other European health systems, where regional differences in access to anti-D immunoglobulin persist despite uniform clinical guidelines (16). International evidence further highlights that incomplete documentation and limited traceability of administration episodes continue to constrain effective monitoring of this intervention (17). From a clinical perspective, inadequate prophylaxis exposes Rh-negative pregnant women and their newborns to the risk of hemolytic disease, a preventable condition associated with increased neonatal morbidity (18).

The upward trends observed in newborn hearing screening and retinopathy of prematurity (ROP) screening coverage reflect progressive alignment of local services with European standards and improvements in technical capacity. These findings support the effectiveness of neonatal screening as a public health intervention for early detection of conditions with potentially irreversible consequences. However, the decline identified in post-screening follow-up among preterm infants highlights a critical vulnerability in the continuum of care. The literature consistently emphasizes that screening effectiveness depends not only on early identification but also on functional referral and follow-up pathways that ensure diagnostic confirmation and timely intervention, in accordance with ethical standards for research and clinical practice (19, 20). In the absence of such mechanisms, the overall public health impact of screening programs remains limited. The observed patterns suggest that organizational factors, including fragmented coor-

dination between maternity services, neonatology units, specialized outpatient care, and primary care, play a central role in loss to follow-up, a phenomenon also reported in other European settings (23).

Nutritional interventions display differentiated trends. The increasing coverage of nutritional prophylaxis among low-birthweight infants indicates effective identification and enrollment of a high-risk population group, demonstrating that targeted interventions can achieve high coverage when supported by clear eligibility criteria and coordinated delivery. In contrast, the declining proportion of infants receiving formula milk in the absence of breastfeeding presents a more complex interpretation. While this trend may be consistent with successful promotion of breastfeeding practices in line with international recommendations, it may also reflect persistent access barriers for families unable to breastfeed, particularly in socioeconomically disadvantaged or rural contexts. International evidence underscores the importance of maintaining regulated and equitable access to safe breast milk substitutes to avoid reinforcing nutritional inequalities (15). These findings highlight the need to interpret infant nutrition indicators within a broader equity-oriented framework.

The variability observed across service components and population groups reflects broader territorial inequalities in healthcare delivery. International studies consistently report lower coverage and reduced continuity of care in rural or underserved areas, even in the presence of centralized national policies (21,22). The results from Bacău County suggest that insufficient coordination structures and limited integration between institutional levels may fragment care pathways, reducing overall program effectiveness. Evidence from Southeastern Europe supports the relevance of adaptive governance approaches that emphasize coordination across national, county, and community levels in addressing local barriers to implementation and follow-up (23).

The sustained decline in the number of live births observed during the study period must be interpreted within a broader demographic context. Eurostat data document a long-term decrease in fertility rates and a rise in maternal age across Romania and the European Union (24). These demographic shifts create a dual challenge for maternal and child health services, combining reduced case volumes with increased clinical complexity associated with higher-risk pregnancies. The European Health Report emphasizes the necessity for health systems to integrate demographic realities into service planning and risk management frameworks (25).

This study has several limitations. It relies on administrative data, which may be affected by reporting inconsistencies or incomplete documentation, and it does not capture qualitative dimensions such as provider perspectives or organizational culture. The analysis reflects the specific context of Bacău County and may not be fully generalizable to other regions. In addition, the four-year observation period limits long-term inference, and external legislative, financial, or epidemiological factors may have influenced the observed trends.

CONCLUSIONS

The longitudinal evaluation of maternal and child health services in Bacău County over the 2021-2024 period indicates a heterogeneous pattern of performance across program components. Notable progress was observed in neonatal screening activities,

particularly in hearing screening and retinopathy of prematurity prevention, reflecting improved coverage and consolidation of early detection mechanisms with potential long-term clinical benefit.

Nutritional interventions demonstrated differentiated trends. Coverage among low-birth-weight infants increased steadily, indicating effective identification and inclusion of a high-risk group, whereas the declining proportion of infants receiving formula in the absence of breastfeeding highlights the importance of continuous monitoring to ensure that nutritional vulnerabilities are not overlooked.

Immunoprophylaxis against Rh isoimmunization showed variable coverage over time, suggesting that, despite functional implementation, full and stable protection of the target population has not yet been achieved. In addition, the decreasing continuity of post-screening follow-up among preterm infants represents a critical limitation, emphasizing that improvements in screening coverage must be accompanied by sustained monitoring to achieve their intended health impact.

The persistent decline in the number of live births observed during the study period further underscores the need for adaptive service planning in the context of demographic change, characterized by reduced case volumes and increased clinical complexity. Overall, the findings highlight both the consolidation of key preventive interventions and the persistence of organizational and continuity-related challenges, shaping a nuanced picture of maternal and child health service performance at the county level.

ACKNOWLEDGEMENTS

The authors acknowledge the support of the healthcare institutions involved in this study for providing access to administrative data used in the analysis. The authors also thank the medical and administrative staff who contributed indirectly to data collection and validation.

CONFLICT OF INTEREST AND FUNDING

The authors declare no conflict of interest.

This research received no external funding. The study was conducted as part of a doctoral research project Research on the management of the National Programme for Women's and Children's Health at the level of Bacău County: implementation, monitoring, evaluation, and efficiency at the Grigore T. Popa University of Medicine and Pharmacy Iași, Doctoral contract no. 1916/29.10.2021.

ASSOCIATION BETWEEN LIFESTYLE FACTORS AND OSTEOPOROSIS: A CROSS-SECTIONAL STUDY IN A ROMANIAN POPULATION (Abstract): Osteoporosis is a major public health problem characterized by reduced bone mass and increased fracture risk. Lifestyle factors play an important role in its development and prevention. This study examines the relationship between lifestyle factors and osteoporosis in an adult Romanian population, providing recommendations for prevention through adequate calcium and vitamin D intake and the promotion of a healthy lifestyle. **Aim:** To evaluate the association between lifestyle habits and the presence of osteoporosis. **Materials and methods:** A cross-sectional study was conducted on 160 participants using an online questionnaire. Variables analyzed included age, sex, BMI, smoking status, physical activity, and supplement use. Statistical analysis was performed using chi-square tests, point-biserial correlations, and multivariate logistic regression ($p<0.05$). **Results:** The prevalence of osteoporosis was 13.12%. Age was the only factor significantly associated with osteoporosis ($r=0.453$; $p < 0.001$) and remained an independent predictor in logistic regression (OR=1.15; 95% CI: 1.08-1.21; $p<0.001$). No significant associations were found for sex ($p=0.19$), BMI, smoking, or physical activity ($p>0.05$). Supplement use was statistically significant ($p<0.001$), but likely influenced by reverse causality. **Conclusions:** The study highlight the importance of screening and early prevention, contributing to a better understanding of osteoporosis epidemiology in Romania. Lifestyle habits significantly influence osteoporosis risk. Public health interventions focusing on prevention, education, and modifiable risk factors are essential for reducing the burden of osteoporosis. **Keywords:** BONE DENSITY, OSTEOPOROSIS, BONE HEALTH, MENOPAUSE.

INTRODUCTION

Bone health depends on patients' diet and lifestyle. Dietary intake of calcium, vitamin D, and proteins are essential factors for maintaining bone strength throughout life, as well as for reducing bone density loss, a phenomenon specific to aging.

The risk of osteoporotic fractures results from a combination of factors that act mainly by reducing bone mineral density, but also from factors that are completely or partially independent of it. Numerous factors are associated with osteoporotic fractures, such as: reduced peak bone mass, hormonal factors, use of certain medications (e.g., glucocorticoids), smoking, low levels of physical activity, low dietary intake of calcium and vitamin D, race, small body constitution, as well as a personal or family history of osteoporosis or other associated conditions (1).

Age is a major determining factor of os-

teoporosis, with a marked increase in risk after the age of 61. Other factors have also been identified, such as higher BMI, which appears to have a protective effect due to mechanical loading and higher estrogen levels from adipose tissue; a vegetarian diet, which is associated with an increased risk of osteoporosis; and living environment-urban residents showed a slightly lower risk compared to those in rural areas, although the difference was not statistically significant. Men have a lower risk compared to women, which can be explained by hormonal factors and body composition (2).

Osteoporosis is a major public health problem, associated with bone fragility and an increased risk of fractures, and maintaining an adequate intake of calcium and vitamin D represents the foundation of prevention and treatment interventions (3).

MATERIALS AND METHODS

The study aimed to evaluate the association between lifestyle habits and bone health status. A questionnaire was developed, including questions related to the assessment of bone health, the presence of bone disorders, patients' lifestyle habits, and family history. The questionnaire was approved by the Ethics Committee of the Grigore T. Popa University of Medicine and Pharmacy in Iași, Romania and was administered online, with respondents' confidentiality ensured.

This cross-sectional study aimed to evaluate the association between lifestyle factors and osteoporosis in a Romanian adult population. Data were collected using a structured questionnaire that included items on demographic characteristics, bone health status, lifestyle habits (diet, physical activity, smoking, sun exposure), supplement use, and family history of osteoporosis.

Statistical analysis was performed using SPSS version 30 and JASP software. Descriptive statistics were calculated for all variables. Associations between categorical variables were assessed using the chi-square test, while relationships between continuous and dichotomous variables were evaluated using point-biserial correlation coefficients.

To identify independent predictors of osteoporosis, a multivariate logistic regression analysis was conducted. Osteoporosis diagnosis was included as the dependent variable, while age, sex, BMI (Body Mass Index), smoking status, physical activity, and dietary supplement use were entered as independent variables. Odds ratios (OR) with 95% confidence intervals (CI) were calculated. A p-value < 0.05 was considered statistically significant.

RESULTS

A total of 160 participants were included in the analysis. Osteoporosis diagnosis was self-reported and recorded as a dichotomous variable (yes/no). Independent variables included age (continuous), sex (male/female), body mass index (BMI, continuous), smoking status (yes/no), physical activity (categorical), and dietary supplement use (yes/no).

Data regarding patients' age (21-84 years), gender, body mass index (BMI) (17.6-38.2 kg/m^2), and living environment are presented in table I.

Within the group of respondents, retirees predominate (43.10%), followed by teachers (20.0%). 160 participants completed the questionnaire, of whom 21 (13.12%) reported a diagnosis of osteoporosis, while 139 (86.88%) reported no such diagnosis.

TABLE I.
Characteristics of the respondent group

	Number	Mean ± SD
Age	160	51.72 ± 14.82
BMI	160	26.98 ± 4.43
Gender: Female Male	135 25	84.4% 15.6%
Living environment: Urban Rural	128 32	80% 20%

Descriptive and bivariate analyses showed that most variables, including sex, BMI, lifestyle factors, and place of residence, were not significantly associated with osteoporosis. Age was the only variable demonstrating a statistically significant positive association with osteoporosis, as indicated by point-biserial correlation analysis (rp.bis = .453, $p < 0.001$).

To further evaluate independent associations, a multivariate logistic regression analysis was performed. The results showed that age was significantly associated with osteoporosis (OR = 1.15, 95% CI: 1.08–1.21, $p < 0.001$), indicating that the risk of osteoporosis increases with advancing age. No statistically significant associations were found for sex ($p = 0.19$), BMI ($p > 0.05$), smoking status ($p = 0.37$), or physical activity ($p > 0.05$).

Dietary supplement use was significantly associated with osteoporosis (OR ≈ 0.00, 95% CI: very wide, $p < 0.001$). However, this association is likely explained by reverse causation, as individuals diagnosed with osteoporosis are more likely to use supplements following medical advice.

Out of the 160 respondents, 21 (13.12%) reported having been diagnosed with osteo-porosis, while 139 (86.88%) reported no such diagnosis. Among those without a diagnosis, most had not undergone medical evaluation for osteoporosis (tab. II).

TABLE II.
Association between osteoporosis diagnosis and biological gender

	No	Yes	Woman	Men
Diagnosis	139 (86,9%)	21 (13,1%)	20 (14,81%)	1 (4%)

Regarding the association between an osteoporosis diagnosis and biological sex, based on the questionnaire responses, it was observed that the majority of respondents had not been diagnosed with osteoporosis, and among those who were diagnosed, most were women. The small number of respondents does not allow the results to be generalized to the overall population, and for many patients, according to their own statements, bone mineral density assessment is not a routine evaluation. Therefore, in the analyzed sample, no association was observed between biological sex and the presence or absence of osteoporosis (CC = .116, $\chi^2(1) = 2.16$, $p = .141$),

and the difference between the two sexes was not statistically significant (d = .108, 95% CI [.018, .206]).

Although, from a descriptive perspective, most individuals diagnosed with osteoporosis were women and it might appear that there is a statistically significant association, the statistical analysis did not identify a statistically significant association between biological sex and the presence of osteoporosis in the analyzed sample ($\chi^2(1) = 2.16$, $p = .141 > .05$). The observed difference may be explained by the small sample size and the low number of diagnosed cases.

Of the 21 respondents who reported having been diagnosed with osteoporosis, 3 live in rural areas (14.28%) and 18 (75.72%) in urban areas. The higher proportion of patients diagnosed with osteoporosis in urban areas does not necessarily indicate a higher risk associated with the place of residence, but may be correlated with easier access to medical evaluation services for patients living in urban areas of Romania compared to those in rural areas.

Place of residence was not associated with the presence or absence of osteoporosis (CC = .055, $\chi^2(1) = 0.49$, $p = .482$), even though 11.3% of those diagnosed with osteoporosis live in urban areas and only 1.9% live in rural areas. The difference between the two proportions of individuals from urban and rural areas was not statistically significant (d = .047, 95% CI [−.070, .164]). Although, at a descriptive level, there appears to be a difference between urban and rural environments among individuals with osteoporosis, the inferential analysis conducted on the subgroup of 21 participants does not indicate a statistically significant association.

The high p-value (p = .482), the very small contingency coefficient (CC = .055), and the confidence interval including zero suggest that the observed difference is likely the result of random variation, amplified by the small sample size. Thus, place of residence was not significantly associated with the presence or absence of osteoporosis, $\chi^2(1) = 0.49$, $p = .482$, CC = .055. Although, descriptively, a higher proportion of individuals diagnosed with osteoporosis comes from urban areas compared to rural areas, this difference is not supported by inferential analysis. The difference between the two proportions is not statistically significant and this result can be explained, at least in part, by the small size of the analyzed subgroup (n = 160), which limits the statistical power of the test and makes the observed percentage differences susceptible to random variation.

Figure 1 highlights the relationship between body mass index (BMI) and the presence or absence of osteoporosis. The scatterplot and trend line show a slight downward tendency, but without a clear separation between the two categories, suggesting no obvious association between BMI and osteoporotic status.

Regarding the association between the presence/absence of osteoporosis (a dichotomous variable-i.e., a variable that can take only two mutually exclusive values, usually coded as 0 and 1) and body mass index (BMI, a continuous variable), the null hypothesis was tested. The null hypothesis is a statistical statement assuming no relationship, difference, or effect between the analyzed variables. In statistical testing, the null hypothesis is accepted until the data provide sufficient evidence to reject it.

The point-biserial correlation between BMI and osteoporosis was not statistically significant in the analyzed group, and our

data do not provide sufficient evidence to reject the null hypothesis (rp.bis = –0.036, df = 158, p = .650, 95% CI [–0.190, 0.120]).

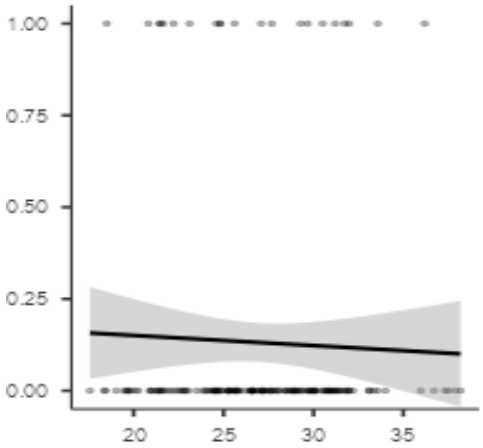

Fig. 1. Association between the presence/absence of osteoporosis and Body Mass Index (On the X-axis are the BMI values, on the Y-axis is the binary osteoporosis variable (0 = absence, 1 = presence). The line represents the estimated probability of osteoporosis, which decreases from about 15% at BMI ≈ 20 to about 10% at BMI ≈ 35, and the gray area indicates the confidence interval of the estimate.)

To evaluate the association between the presence/absence of osteoporosis (dichotomous variable) and BMI (continuous variable), the point-biserial correlation coefficient was used. The null hypothesis assumed no association between the two variables, i.e., a correlation coefficient of zero (H0: rp.bis = 0). The analysis indicated a very weak and statistically non-significant correlation between BMI and osteoporosis (rp.bis = –0.036, df = 158, p = .650, 95% CI [–0.190, 0.120]). Therefore, the data do not provide sufficient evidence to reject the null hypothesis, suggesting the absence of a significant association between BMI and the presence of osteoporosis in the analyzed group.

The same analytical method was used to examine the association between the presence/absence of osteoporosis (dichotomous variable) and participants' age (continuous variable), using the point-biserial correlation coefficient. The null hypothesis assumed no association between age and osteoporosis (H0: rp.bis = 0). The point-biserial correlation coefficient between age and osteoporosis was found to be statistically significantly greater than zero at the population level. The results indicated a statistically significant, positive correlation of moderate-to-high strength between age and the presence of osteoporosis (rp.bis = .453, df = 158, p < .001, 95% CI [.343, .553]). Consequently, the null hypothesis was rejected, providing statistical evidence that the risk of developing osteoporosis increases with age. Age accounts for approximately 20.53% of the variance in the presence/absence of osteoporosis.

Fig. 2 illustrates the relationship between age and the presence/absence of osteoporosis, showing an upward trend in

the likelihood of osteoporosis occurrence as age increases, as suggested by the trend line, without implying a deterministic relationship at the individual level.

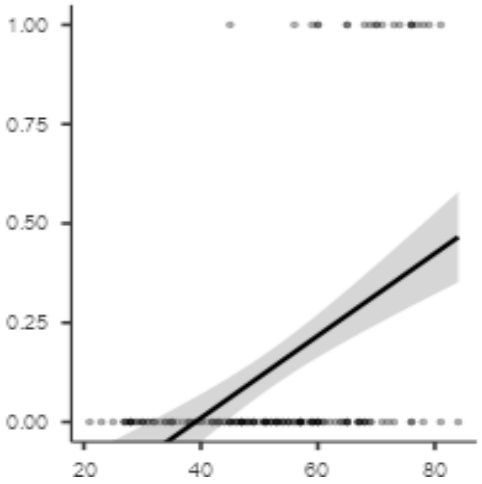

Fig. 2. Association between the presence/absence of osteoporosis and age (On the X-axis, the participants' age is shown, and on the Y-axis, the binary variable for osteoporosis (0 = absence, 1 = presence). The black line indicates the estimated probability of osteoporosis as a function of age, which increases from nearly 0% around ages 35–40 to about 45% at age 80. The gray area represents the confidence interval of the estimate.)

Our data indicate that the null hypothesis can be rejected; therefore, there is evidence to state that the risk of developing osteoporosis increases with age (rp.bis = .453, df = 158, p < .001, 95% CI [.100, .343]), with a strong effect, as approximately 20.53% of the variance in the presence and absence of osteoporosis is explained by age.

Regarding the association between a family history of osteoporosis and the presence or absence of an osteoporosis diagnosis, our data do not indicate a statistically significant association different from zero at the population level (CC = .028, $\chi^2(1)$ = 0.13, p = .721). Among the 21 respondents who reported being diagnosed with osteoporosis, 14 (66.66%) had no family members diagnosed with the condition, while 7 (33.34%) reported having relatives diagnosed with osteoporosis. The difference between the two proportions of individuals with and without a family history of osteoporosis is not statistically significant (d = .021, 95% CI [-.096, .138]).

Analysis of the association between the presence or absence of osteoporosis and the age at menopause onset shows a marginal significance (rp.bis = .153, df = 81, p = .084, 95% CI [-.030, .100]). The null hypothesis H0: The point-biserial correlation coefficient between age at menopause onset and osteoporosis is statistically significantly greater than zero at the population level cannot be rejected. However, it is possible that the effect manifests at the population level, as the analysis has low power, being conducted on 81 cases.

Regarding the relationship between the

age at menopause onset and the presence/absence of osteoporosis, a trend is observed suggesting an increasing probability of osteoporosis with later menopause onset, although this does not imply a definite causal relationship (fig. 3).

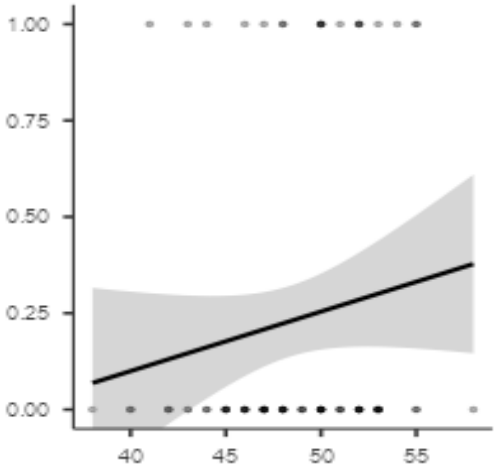

Fig. 3. Association between the presence/absence of osteoporosis and the menopause onset age (On the X-axis is the age at onset of menopause, and on the Y-axis the binary variable of osteoporosis (0 = absence, 1 = presence). The black line indicates the estimated probability of osteoporosis, which increases from about 8–10% for early menopause (~40 years) to about 35% for late menopause (~55–57 years). The gray area represents the confidence interval of the estimate.)

Our data seem to associate the presence of osteoporosis with older ages at menopause onset; however, this observation does not result from statistical analysis. The analysis of the association between the presence/absence of osteoporosis and the age at menopause onset indicates a weak positive trend, but it is not statistically significant, as the p-value is not less than 0.05 ($r_{p\beta}$ = .153, df = 81, p = .084). The 95% confidence interval includes zero, suggesting that the observed association may be due to random variation in the sample.

Consequently, the null hypothesis, which states that there is no association between age at menopause onset and the presence of osteoporosis, cannot be rejected. Although the direction of the coefficient suggests that osteoporosis tends to be associated with later menopause onset, this trend is not statistically supported in the present sample.

The lack of statistical significance may be influenced by the low power of the analysis, due to the relatively small sample size (N = 81). Therefore, the results should be interpreted with caution, and further studies with larger samples are needed to clarify the nature of this relationship.

Regarding fractures, 69.4% reported no fractures. Among those who did, 10.6% occurred in the forearm, 8.1% in the hip, 3.1% in the ribs, 2.5% in the spine, and 1.3% in the pelvis.

Analyzing the association between the

presence or absence of fractures and dairy consumption, our data do not indicate a statistically significant association different from zero at the population level (CC = .001, $\chi^2(1) = 0.00$, p = .991).

Among subjects who reported regular dairy consumption, 30.58% had a history of fractures, while among those who do not consume dairy, 30.66% had fractures. The difference between the two groups was not significant. Considering that osteoporosis and fracture risk are influenced by multiple factors, we cannot assert that dairy consumption alone determines fracture risk in the study group. To avoid misinterpretation of the results and to clarify the causal link between low dairy consumption and fracture risk, it is necessary to increase the number of subjects included in the study and to evaluate the cause of fractures while excluding accidental traumatic fractures.

DISCUSSION

Overall, the multivariate analysis confirmed that age remains the main independent factor associated with osteoporosis in the studied population, while other lifestyle variables did not show significant independent effects.

A decrease in bone density is a pathological phenomenon more frequently observed in women than in men. Regardless of sex, the prevalence of osteoporosis increases significantly with age, being observed in 50% of men and 80% of women over the age of 65 (1, 4).

The data presented in this study highlight the need for much more careful assessment of bone density in patients, as in our study many of the 160 individuals who completed the questionnaire had not undergone a bone density evaluation. Such evaluation is necessary because other studies have shown that one in two women and one in four men will experience, during their lifetime, a fracture caused by osteoporosis (2, 5).

The environment in which patients live can influence the rate of osteoporosis diagnosis. For instance, a study conducted in Spain, which included postmenopausal women showed a higher incidence of osteoporosis among women from rural areas. Specifically, 36.5% of rural women were diagnosed with osteoporosis, compared to 28.7% of urban women. Women from rural areas were generally older, shorter, and had a higher BMI compared to those from urban areas (6).

Similarly, a study conducted in China observed that among menopausal women, 26.83% of those living in urban areas and 32.53% of those in rural areas had osteoporosis. Studies on the general population reported a prevalence of osteoporosis of 10.33% in rural areas and 5.52% in urban areas (7).

The prevalence of osteoporosis depends on BMI and is inversely proportional to it. Multivariate analyses (which consider multiple factors simultaneously), adjusted for factors associated with osteoporosis, showed that underweight individuals had a significantly higher risk of osteoporosis compared to those with normal weight. In contrast, overweight and obese individuals had a lower risk of osteoporosis compared to those with normal weight (8, 9).

Underweight individuals with a BMI < 20 kg/m² had high risk for fracture compared with those with a BMI of 25 kg/m² (10).

A study conducted in China reported a prevalence of osteoporosis of 4% among men aged 50–59 years, 7.2% in those aged 60–69 years, 15.1% in the 70–79 age

group, and 26.7% in those over 80. For the same age groups, women showed a prevalence of 15.2%, 36.5%, 62.7%, and 85.8%, respectively. The onset age of osteoporosis was observed as follows: femoral neck osteoporosis began at 55 years in women and at 60 years in men (11).

Aging and the onset of osteoporosis are closely related (11). The overall decline in bone strength is due to reductions in both trabecular and cortical bone density, thinning of cortical bone, and a marked increase in its porosity. Loss of spongy (trabecular) bone mass in humans begins around the age of 30, while cortical bone density starts to decrease after the age of 50. In women, bone loss accelerates after menopause, so estrogen deficiency negatively affects bone mass and accelerates the deterioration of the skeletal system with age (12).

Osteoporosis has a high degree of heritability, but genetic factors alone are not sufficient to explain fracture occurrence in offspring, especially in adulthood (13).

The Geelong Osteoporosis Study conducted in Australia showed that a mother's fracture was associated with a higher likelihood of early fractures in daughters. Conversely, a father's fracture was associated with an increased risk of early fractures in sons, but not in daughters. Therefore, parental fracture history appears to be associated with the risk of early fractures in children in a sex-specific manner (14).

A questionnaire-based study conducted in the United States, including 8,073 women over the age of 20, showed a significant correlation between family history of osteoporosis and osteoporosis risk. The prevalence of family history was 34.8% among women with osteoporosis and 18.5% among those without the condition. Women who reported that their mother had osteoporosis had a higher risk than those who did not report this (15).

Studies on families and twins indicate that 50–85% of variations in bone mineral density are genetically determined. To reduce fracture risk, treatment for women with a family history of fractures can be initiated at a less strict bone density threshold, potentially improving patient compliance with subsequent interventions (16-18).

Large-scale genomic studies have identified several genetic variants that may contribute to the determination of bone mass and fracture risk, each having a moderate effect (19).

The process of bone density reduction begins one year before menopause, continues intensely for three more years, then slows slightly but continues at a moderate pace for another 4–8 years. On average, bone density decreases by approximately 10% during the menopausal period. In some women, loss can reach up to 20% over the 5–7 years surrounding menopause (20).

A study conducted in Sweden between 1977 and 2011 showed that at the age of 77, 56% of women with early menopause had osteoporosis, compared to only 30% of those with late menopause, indicating an almost twofold increased risk (1.83 times higher) of osteoporosis for women with early menopause. Women with early menopause had a higher incidence of fractures compared to those with late menopause, corresponding to a 1.68 times higher risk of experiencing such fractures (21, 22).

Milk and dairy represent an important source of protein, calcium, and other essential nutrients, and their consumption should not be discouraged in at-risk populations (23). According to a study from Sweden, consumption of fermented milk products

(yogurt, kefir) was associated with a lower risk of fractures, and when combined with fruit intake, it increased the rate of antioxidant protection (24).

The Age, Gene/Environment Susceptibility-Reykjavik (AGES-Reykjavik) study in Iceland reported a positive association between milk consumption and volumetric bone density at baseline, with an adjusted sex- and age-specific difference of 8.95 ± 2.5 mg/cm³ between the highest and lowest milk consumption categories (25). The regular lifelong milk consumption, from adolescence to old age, is associated with higher bone density in later life (26).

CONCLUSIONS

In this Romanian adult population, age was the primary factor associated with osteoporosis, while most lifestyle factors assessed through self-reported data were not significantly related to the condition. The findings emphasize the importance of age-based screening and clinical evaluation for osteoporosis. Larger population-based studies using objective measurements of bone mineral density are needed to better clarify the contribution of lifestyle factors to osteoporosis risk in this population.

CONFLICT OF INTERESTS AND FUNDING

PSYCHOLOGICAL PROFILE OF FRESHMAN PHARMACY STUDENTS (Abstract): In the last decades, the role of pharmacists has changed, and new tasks are required for the care of patients. Good communication skills, rapid adjustment to new techniques and research abilities must be developed during academic formation. **Aim**: the goal of the study is to shape the psychological profile of freshman pharmacy students. **Material and methods**: 106 freshman pharmacy students were asked to fill in a socio-demographic data sheet and to answer the items of four instruments: *Maslach Burnout Inventory* (measuring burnout), *Toronto Alexithymia Scale* (measuring the level of alexithymia), *Big Five Inventory* (identifying personality traits) and *Beck Depression Inventory* (evaluating depression). The statistical analysis of data was done using *SPSS Statistics 23.0.0* for MAC.OSX. **Results**: the results identified an average level of emotional exhaustion, a low level of depersonalization and a high level of personal achievement. The scores for alexithymia prove that a possible alexithymia and a mild level of depression was identified for freshman pharmacy students. Comparative results and correlation analysis are presented. **Conclusions**: the results are important for the pharmacy students to identify their personality traits and for the academic staff to adjust the educational curricula to cover the needs for professional development.
Keywords: PHARMACY STUDENT, DEPRESSION, PERSONALITY TRAITS, ALEXITHYMIA, BURNOUT, PSYCHOLOGICAL PROFILE.

The role of pharmacists has changed over the years, becoming more focused toward patient-centered care. This new targeted orientation has been sustained by the extended need of community pharmacy and by the inclusion of the chronic patient and family in the medical decisions. So, both community and hospital pharmacists were pressed to better adjust to the patient's profile and to develop more strategies to cope with stress related to the new job tasks. More abilities are now needed to develop a good relationship with patients. Also, better strategies should be applied to cope with stress related to job.

Not many studies can be found in the scientific literature about the pharmacist's psychological profile and its relationship with work. The need for this kind of research is great, because some studies proved that pharmacists were disappointed about their job performances and accused the lack of research knowledge, training, mentorship and support for their profes-

sional development and practice (1). Few studies suggest that there is a possible interaction between pharmacists' personality traits and pharmacists' performance (2) and their organizational culture profile (3).

The need for the quality of care increased over the years, abandoning the need for the traditional role in the community or hospitals. The new role demands the pharmacist to be a part of the medical team and to be in charge with hospitalized patients. In the community, pharmacists play an important role together with the family physicians. Preparing themselves to properly integrate into the community and into the medical team will assure a high level of work satisfaction for pharmacists and will also improve the quality of care for their patients. For these reasons, professional training during academic years or continuing education must consider the psychological profile of pharmacists and the possibility to improve and develop new skills for them.

Our study wants to identify the presence of some personality traits among freshman pharmacy students at the beginning of their education for this profession.

MATERIAL AND METHODS

The present research was conducted at the "Grigore T. Popa" University of Medicine and Pharmacy of Iasi (June-September 2017), all the participants being students of this institution.

The study protocol of this cross-sectional, self-administered questionnaire was approved by the institutional ethical committee and informed consent was obtained from the participants prior to the beginning of the study.

The students from Pharmacy Faculty had to fill in a socio-demographic data sheet (registering socio-demographic characteristics, academic results, family data about siblings and parents' level of education or the presence of a chronic disease) and to answer to the items of four psychological instruments, to identify the personality traits and alexithymia and to evaluate the level of depression and burnout.

1. Burnout among medical students was assessed using the *Maslach Burnout Inventory* (MBI), the most frequently used questionnaire for measuring burnout. The MBI has 3 subscales to evaluate each domain of burnout: emotional exhaustion (the feeling of being emotionally drained by one's work, Cronbach's alpha = 0.809), depersonalization (emotional coldness, cynicism, feelings of guilt, social withdrawal, Cronbach's alpha = 0.690) and personal achievement (feelings of accomplishment in one's work, Cronbach's alpha = 0.862).

2. The personality traits were evaluated with the help of *Big Five Inventory* (BFI) which consists of 44 items corresponding to the five personality factors of the Big Five model: extraversion (Cronbach's alpha = 0.839), agreeableness (Cronbach's alpha = 0.678), conscientiousness (Cronbach's alpha = 0.820), neuroticism (Cronbach's alpha = 0.714), openness to experience (Cronbach's alpha coefficient = 0.703).

3. Alexithymia, a psychological construct that refers to people's difficulty in identifying and describing emotions because they focus their attention externally was measured using the *Toronto Alexithymia Scale (TAS – 20)*, a 20-item self-administered questionnaire. TAS-20 has 3 subscales: difficulty describing feelings or emotions (Cronbach's alpha = 0.804), diffi-

culty identifying feelings or emotions (Cronbach's alpha = 0.795), and externally oriented thinking (Cronbach's alpha = 0.336), Chronbach's alpha for alexithymia total score = 0.803.

4. *BECK Depression Inventory* (*BDI* - Beck et al, 1961), one of the most used instruments for the assessment of depression contains a number of 21 items which represent the symptoms used to diagnose depression: mood, pessimism, sense of failure, lack of satisfaction, guilty feelings, sense of punishment, self-hate, self-accusations, self-punitive wishes, crying spells, irritability, social withdrawal, indecisiveness, body image, work inhibition, sleep disturbance, fatigability, loss of appetite, weight loss, somatic preoccupations and loss of libido. The answers range from 0 to 3 and the alpha Chronbach score for this inventory is 0.861.

The statistical analysis of data was done using SPSS Statistics v23.0.0 for MAC.OSX. For the comparisons we used the t-test for independent samples and one-way ANOVA and for the correlational analysis we used Pearson and Spearman correlations. The statistical difference was defined as $p < 0.05$.

RESULTS AND DISCUSSION

Socio-demographic data. Among the 106 freshman pharmacy students, 10 are male and 96 females, aged between 18 and 42 (M = 19.92 ± 2.69), enrolled in the 1st year of study. The sex distribution is according to the specificity of the profession (more women than men work in the pharmaceutical area). A percent of 31.4% are singleton, 47.6% have one sibling and 11.4% have 2 siblings and 68 % of students live in an urban.

Regarding academic results, the admission grades of subjects ranged between 5.40 and 9.94 (M = 8.10 ± 1.16**).**

Considering the level of education of both parents, almost half of the students declared that their mothers (45.2%) and fathers (46.7%) have at least a high school degree. 19.3% of students have at least one parents working abroad. More than half of subjects (65.6%) live by themselves in a dorm/rented apartment.

Most of pharmacy students (95.3%) declared that they do not suffer from any chronic diseases.

Psychological results. The results obtained by our participants for the questionnaires they filled in can be observed in tab. I. The results show that regarding burnout, students obtained an average level of emotional exhaustion, a low level of depersonalization and a high level of personal achievement. The scores for alexithymia evaluated with TAS-20 prove that there is a possible alexithymia and the results for BDI show a mild level of depression among freshman pharmacy students.

These results show that regarding burnout, the subjects have an average level of emotional exhaustion, a low level of depersonalization and a high level of personal achievement. The scores for alexithymia evaluated with TAS-20 are proving that there is a possible alexithymia while the score obtain at BDI show a mild level of depression among the pharmacy students.

The blend of personality traits (like openness, conscientiousness) are often related to job performance, work efficiency, less errors and good communication skills, while neuroticism and introversion act like barriers in the ability to complete a task correctly (4, 5).

TABLE I
Results obtained for MBI, BFI, TAS-20 and BDI

Instruments	Dimensions	M ± standard deviation
MBI	emotional exhaustion	**17.66 ± 9.20**
	depersonalization	**2.89 ± 4.04**
	personal achievement	**25.33 ± 12.03**
BFI	extraversion	3.58 ± 0.73
	neuroticism	3.78 ± 0.52
	openness	3.49 ± 0.67
	conscientiousness	3.10 ± 0.64
	agreeableness	3.45 ± 0.53
TAS-20	difficulty describing feelings	15.23 ± 4.64
	difficulty identifying feelings	19.46 ± 5.80
	externally oriented thinking	17.89 ± 3.99
	total score for alexithymia	**52.59 ± 11.09**
BDI	Mood	0.37 ± 0.60
	Pessimism	0.36 ± 0.48
	Sense of failure	0.32 ± 0.56
	Lack of satisfaction	0.55 ± 0.69
	Guilty feelings	0.37± 0.65
	Sense of punishment	0.61 ± 0.88
	Self-hate	0.28 ± 0.45
	Self-accusations	0.83 ± 0.99
	Self-punitive wishes	0.09 ± 0.38
	Crying-spells	0.39 ± 0.76
	Irritability	0.64 ± 0.86
	Social withdrawal	0.39 ± 0.62
	Indecisiveness	0.65 ± 0.72
	Body image	0.34 ± 0.85
	Work inhibition	0.46 ± 0.63
	Sleep disturbance	0.65 ± 0.55
	Fatigability	0.82 ± 0.71
	Loss of appetite	0.57 ± 0.83
	Weight loss	0.31 ± 0.54
	Somatic preoccupations	0.53 ± 0.69
	Loss of libido	0.20 ± 0.55
	Total score BDI	**10.08 ± 7.40**

Correlational analysis. To perform the correlational analysis, we tested the normality of our data distribution with the Kolmogorov-Smirnov test for all the variables we investigated. The results we obtained showed that the scores for agreeableness, conscientiousness, neuroticism, emotional exhaustion, openness, difficulty

describing feelings, externally oriented thinking and total score for alexithymia have a normal distribution while extraversion, depersonalization, personal achievement, difficulty identifying feelings and the total score for BDI are not distributed normally. That is why we used Pearson correlations for the variables that have a normal distribution and Spearman correlations for the ones that are not distributed normally.

TABLE II

Correlational analysis considering BFI, TAS-20 and MBI dimensions

Variables	Extra-version	Agreeableness	Conscientiousness	Neuroticism	Openness
Emotional Exhaustion	**R = -.213*** **p = .029**	R = -.016 p = .870	R = -.175 p = .073	R = .158 p = .105	R = .028 p = .788
Depersonalization	**R = -.222*** **p = .022**	R = -.177 p = .070	R = -.068 p = .491	R = .024 p = .811	R = -.071 p = .470

The results we obtained show that personality traits strongly correlate with a lot of the variables we investigated in this study:

- extraversion negatively correlates with emotional exhaustion, depersonalization, difficulty describing feelings, difficulty identifying feelings, externally oriented thinking, and the total score for depression, meaning that the more present this personality trait is in a person's personality structure, the lower are the scores for those variables.
- agreeableness negatively correlates with the total score for depression and positively correlates with personal achievement, so we can say that the more agreeable a person is, the more accomplished and the less depressed they will feel.
- conscientiousness negatively correlates with difficulty identifying feelings, the total score of alexithymia and the total score for depression and positively correlates with personal achievement, so the more conscientious a person is, the more personal accomplished they will feel, and they will experience less difficulties in identifying feelings.
- neuroticism positively correlates with difficulty describing feelings, difficulty identifying feelings, externally oriented thinking, the total score of alexithymia and the total score for depression, which means that the more present neuroticism will be in a person's personality structure, the more difficulties they will have to describe and

identify feeling and the more depressed they will feel.

- openness correlates with externally oriented thinking and the total score of alexithymia, proving that the more open a person will be, less difficulties they will have in being in touch with their feelings.

Table III presents the correlations between the burnout dimensions: emotional exhaustion, depersonalization and personal achievement and the alexithymia factors: difficulty describing feelings, difficulty identifying feelings, externally orientated thinking and the total score for alexithymia and the correlations between the total score for Beck Depression Inventory and the burnout dimensions and the alexithymia factors and alexithymia total score.

TABLE III
Correlational analysis between variables

Variables	Emotional Exhaustion	Depersonalization	Personal Achievement	Total Score BDI
Difficulty describing feelings	R = .264** p = .006	R = .088 p = .371	R = - .060 p = .541	R = .285** p = .003
Difficulty identifying feelings	R = .244* p = .012	R = .157 p = .689	R = .004 p = .967	R = .479** p = .000
Externally oriented thinking	R = .243* p = .012	R = .151 p = .123	R = -.028 p = .773	R = .157, p = .107
Total score for alexithymia	R = .337** p = .000	R = .174 p = .074	R = -.036 p = .716	R = .438** p = .000

The results show that emotional exhaustion positively correlates with all alexithymia dimensions and the alexithymia total score and with the self-assessed level of depression, meaning that the more emotional exhausted a person feels, the more difficulties they will have in recognizing their emotions and, also, the more depressed they will feel.

The total score for BDI positively corelates with the first two factors of alexithymia: difficulty describing feelings and difficulty identifying feelings and with the total score for alexithymia, meaning that the more depressed a person feels, the more difficulties they will have with being in touch with their emotions.

It is important that these results are taken into consideration during academic formation, results proving that high scores for alexithymia are strongly related with high levels of emotional exhaustion and depression. For the students presenting these traits, the professional training must include strategies to inform and teach them how to cope with professional stress and how to prevent depression.

Comparative analysis. To perform the comparative analysis, we used Independent Samples T-Test for the variables that have 2 levels and for the parents' level of education, and because this variable has more than two levels, we used for the comparisons, One-Way ANOVA.

Variables like gender, accommodation (if they live in a dorm or with rent), chronic disease (if they suffer or not from a chronic disease) produced no differences in the burnout factors emotional exhaustion, de-

personalization, personal achievement neither when it comes to the alexithymia factors, difficulty describing feelings, difficulty identifying feelings and externally oriented thinking or the alexithymia total score and they did not produce any difference regarding the level of self-reported depression.

Socio-demographic characteristics. Environment (urban/rural) produced no differences in emotional exhaustion, depersonalization, difficulty describing feelings, difficulty identifying feelings, externally oriented thinking, total score for alexithymia, total score BDI. The only statistically significant difference we obtained was regarding the level of personal achievement t (102) = -2.272, p = 0.025, the students that live in a rural area feeling more personally accomplished than the students who live in an urban area (Murb = 23.59, Mrur = 29.34).

Parents' level of education. In order to identify if the parents' level of education impacts student's results obtained on all four test, we made a comparative analysis. Most of the results revealed no influence on students' scores. We found that there are significant differences considering:

- the personal achievement dimension of burnout, students whose mothers have a university degree felt more personally accomplished than the students whose mothers have a college degree (Mcoll = 19.28, Muniv = 27.75, F(2,101) = 3.795, p =.026),
- difficulty identifying feelings dimension of alexithymia, the students whose fathers have a university degree having more difficulties in identifying feelings than those students whose fathers have a college degree (Mcoll = 22.04, Muniv = 18.32, F(2,102) = 3.008, p = .054).

The results of this study are important, firstly because they are identifying the psychological profile of freshman pharmacy students, this being the first study of this kind in the country. Secondly, the results are sustained by the scientific literature proving that knowing the personality traits is important for the academic formation, for the continuing professional development for pharmacists and for their quality of professional life and for the quality of care. Understanding the importance of personality traits for pharmacists' practice will provide insights for the development of professional training and support programs tailored specifically for this group (6).

Regression analysis. The analysis of correlations emphasized the influence of certain personality factors on burnout dimensions. To identify the most effective model in predicting burnout, we used multiple linear regression by the hierarchic method. The results are presented in tab. IV.

The results show that for the emotional exhaustion criterion the first three predictive models were significant. The strongest predictive model is the first one that has extraversion as predictor which explains 4.5% of the variance of the criterion emotional exhaustion. This predictor (p = 0.015, b = -2.957, beta = -0.235) has a significant influence on emotional exhaustion, their effect on the criterion being a negative one. The result proves that the more extraversion students show, the less amount of the emotional exhaustion they will experience.

Regarding the depersonalization criterion, the first four predictive models were statistically significant, but the best predictive model is the second model, with extraversion and agreeableness as predictors.

This model explains 6.6% of the variance of depersonalization. Among the 2 predictors of this model, only the second one, agreeableness (p = 0.028, b = -1.680, beta = -0.218), has a significant influence on the criterion, its effect on depersonalization being a negative one. This result proves that the more agreeableness is present in a person's personality structure, the lower their depersonalization scores will be.

TABLE IV
Regression analysis

	Models		Emotional exhaustion	Depersonalization	Personal accomplishment
Step 1	Extraversion	R^2adjusted	0.046	0.031	0.019
		ΔR^2	0.055	0.040	0.028
		F	**6.094***	**4.316***	3.023
Step 2	Extraversion, agreeableness	R^2adjusted	0.039	0.066	0.048
		ΔR^2	0.002	0.044	0.038
		F	**3.156***	**4.728***	**3.635***
Step 3	Extraversion, agreeableness, conscientiousness	R^2adjusted	0.047	0.064	0.058
		ΔR^2	0.017	0.006	0.019
		F	**2.728***	**3.384***	**3.144***
Step 4	Extraversion, agreeableness, conscientiousness, neuroticism	R^2adjusted	0.044	0.058	0.050
		ΔR^2	0.006	0.003	0.002
		F	2.214	**2.615***	**2.392***
Step 5	Extraversion, agreeableness, conscientiousness, neuroticism, openness	R^2adjusted	0.049	0.049	0.045
		ΔR^2	0.014	0.000	0.004
		F	2.087	2.077	1.986

*** p<.001, ** p<.01, *p<.05

For the personal accomplishment criterion only the second, third and fourth predictive models were statistically significant, but the best predictive model is model 3, that has as predictors extraversion, agreeableness and conscientiousness, which explain 5.8% of the variance of personal achievement. Among the 3 predictors of this model, none of them has a significant influence on personal accomplishment.

The importance of the study and some limitations

This study is important because it covers some missing data from the international scientific literature regarding the psychological profile of students studying pharmacy. This research also has some limitations: Firstly, there is a small number of male subjects, so no comparative analysis could be done. Secondly, this study is not a cross-sectional one and differences between students from all years of study were not emphasized. The third limitation is because one of the variable studied (burnout) is more common in the last years of study and not in freshman students. Considering these limitations, some results cannot be generalized.

CONCLUSIONS

Because personality traits are related to job performance and work satisfaction, the results are important for shaping training programs for pharmacy students during their academic years to develop their abilities and to help them adjust to the professional needs. The findings are important for both students and teachers. The awareness of the importance of personality for personal and professional outcomes could improve the path of the development of pharmacists, starting with the very first year of academic education.

ACKNOWLEDGMENTS

NEWS

MALIGNANT POTENTIAL OF SMALL GASTROINTESTINAL TUMORS

Gastrointestinal stromal tumors (GISTs) are sarcomas of the gastrointestinal tract with variable clinical behavior, pathological features and molecular mechanisms. While tumor size is an important prognostic factor, data regarding the malignant potential of small GISTs (<2 cm in size) has yet to be evaluated. The aim of the study was to asses the risk of malignancy in regards to small tumor size. A study was conducted as a review of a population-based cohort of GISTs with known mutational status. In the cohort more than 70% of GISTs were incidental findings, with over a quarter of the tumors less than 2 cm. Among these, 66% had typical C-KIT mutation, either in exon 9 or 11, none had PDGFRA mutation and one third were classifiable as 'wild-type' GISTs. Mutation index was very low (< 5 mitosis/HPF) and the survivability of these patients remained high. Small GISTs are often incidental findings, with more than one in four less than 2 cm in size. The prognosis of these tumors is excellent. Additional data is needed to properly assess the risk of malignancy to avoid overt undertreatment (Søreide K. Cancer biology of small gastrointestinal stromal tumors (<2 cm): What is the risk of malignancy? *Eur J Surg Oncol* 2017; 43(7): 1344-1349).

LATE DIAGNOSED PHACE SYNDROME BY ANEURYSMAL SUBARACHNOID HEMORRHAGE. CASE REPORT: PHACE syndrome is a neurocutaneous disorder coined in 1996, but the clear criteria of diagnostic were established in 2009. Even though the age of the diagnostic for the disease is during childhood, we present the case of a patient with PHACE syndrome with late diagnostic, at the age of 59-year-old by aneurysmal subarachnoid hemorrhage. The particularity of this case is represented by the paucity of the diagnostic criteria, respectively the presence of facial hemangioma and the dysplasia of the cerebral arteries at the level of Willis's circle, associated with two aneurysms: ruptured aneurysm of the right posterior communicating artery and unruptured aneurysm of junction P1-P2 of the left posterior cerebral artery. The aim of the article is to height line the importance of early diagnostic of PHACE syndrome and the prevention of complications. **Keywords:** PHACE, SYNDROME, CEREBRAL VASCULAR DYSPLASIA, SACCULAR ANEURYSM.

PHACE syndrome is a neurocutaneous syndrome coined in 1996 by the American professor of dermatology Frieden (1), and referred to the association: posterior fossa anomalies (P), hemangiomas of the face and scalp (H), arterial lesions (A), cardiovascular abnormalities (C) and eye's anomalies (E). When they are associated also supraumbilical raphe (S) or sternal clefting (S), it is called PHACES syndrome (2, 3).

PHACE syndrome appears mainly in women in 90% (1), suggesting that it could represent an X-chromosome-linked dominant condition with lethal potential in the male population. Anyway, familial cases have not been reported (4). Siegel *et al*. (5) made the first step in showing a potential genetic basis of PHACE syndrome, reporting the presence of a genomic copy number variation in patients having this syndrome. Till date, the pathogenesis of this syndrome is unknown (1).

CASE REPORT

We present the case of a patient aged 59, who was admitted at the Clinic of Neu-

rosurgery "Prof. Dr. Nicolae Oblu" Emergency Clinical Hospital, Iasi, for the appearance of an intracranial hypertension syndrome dominated by severe headache. The examination underlined the presence of a facial hemangioma at the level of the left upper and lower eyelid, chin, the left cheek, respecting the alar nasal sulcus (figure 1). At the level of the left cheek, there was a scar in shape of heart ("heart" pseudo-sign) due to a free skin graft, which is mentioned in the personal medical history of the patient when she was 11 years old (fig.1). Computed tomography angiography (CTA) of the head and 3D reconstructions diagnosed a subarachnoid hemorrhage (SAH) (fig.2. A), cerebral vascular dysplasia (fig. 3), as well as a ruptured aneurysm of right posterior communicating artery (PCoA) (fig. 2. B and 3. A.), and a unruptured aneurysm of junction P1-P2 of the left posterior cerebral artery (PCA) (figure 3. B). The cerebral angiography confirmed the presence of the vascular dysplasia (figure 4.A), as well as the aneurysms (figure 4. B). It was not noticed the presence of other anomalies of the eyes or internal organs.

Fig. 1. Facial hemangioma in the distribution of segments 2 and 3. It is noticed the absence of cutaneous distribution of the trigeminal nerve, as do the "port wine stains" in Sturge Weber syndrome. It is also noticed the presence of a free skin graft with aspect of "heart".

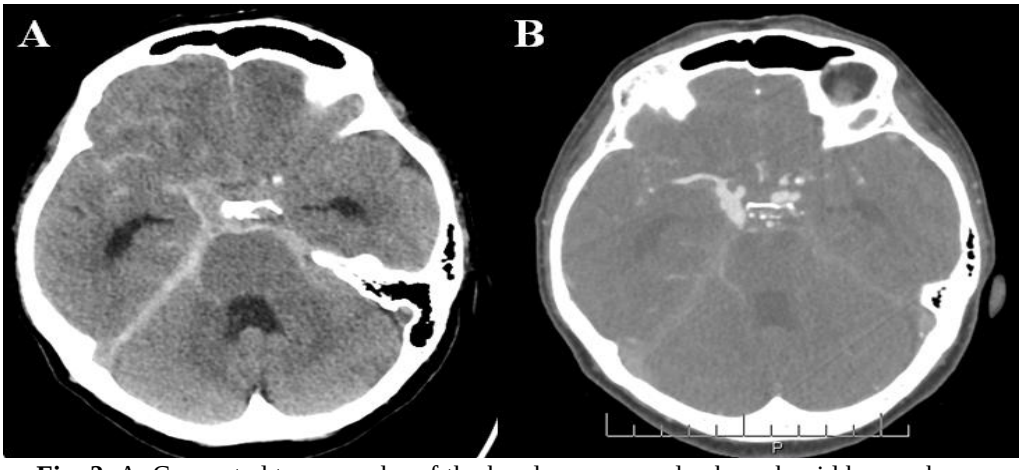

Fig. 2. A. Computed tomography of the head: aneurysmal subarachnoid hemorrhage; B. CTA: vascular dysplasia and right PCoA aneurysm.

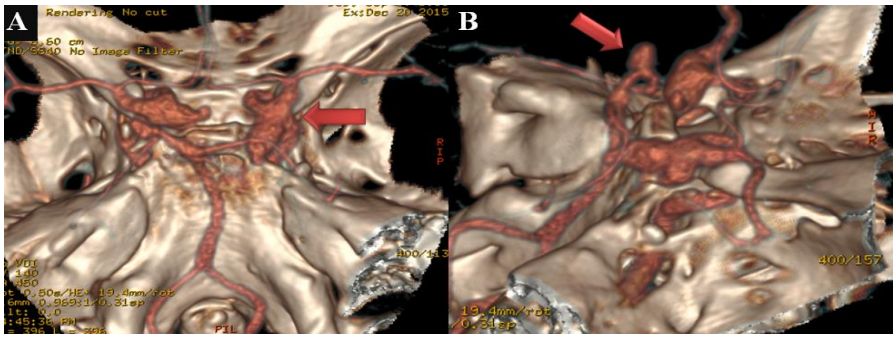

Fig. 3. A, B. CTA of the head with 3-dimensional reconstruction of the intracranial vessels showing dysplasia with right PCoA aneurysm (3. A, red arrow) and P1-P2 junction aneurysm (left PCA) (3. B, red arrow).

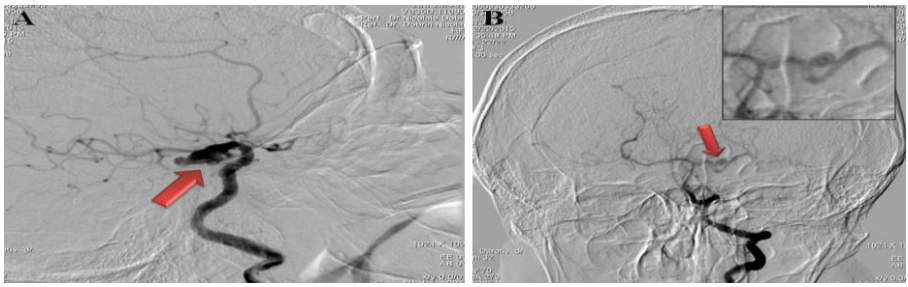

Fig. 4. Cerebral angiography: A. Lateral right view with vascular dysplasia (red arrow); B. Left vertebral artery view with P1-P2 junction aneurysm from left PCA (Dr. N.Dobrin's collection).

DISCUSSION

Criteria of diagnostic. Pascual-Castroviejo (6) was the one who proved for the first time the relationship between infantile hemangiomas and malformations of the cervical and cerebral arteries in a disease that he called "cutaneous hemangioma-vascular complex syndrome". In 1996, Frieden (1) suggest the acronym PHACES. The clear criteria of diagnostic for this syndrome were established in 2009 by the American Academy of Pediatrics, who classified them into two categories: 1. PHACE syndrome and 2. possible PHACE syndrome. Also, it has established the major and minor criteria that were determinate by following these organ systems: structural brain, cerebrovascular, cardiovascular, ventral or midline. Thus, definitive PHACES syndrome requires the presence of: facial hemangioma > 5 cm in diameter + 1 major criteria or 2 minor criteria; possible PHACES syndrome requires the presence of: facial hemangioma > 5 cm + 1 minor criteria, or hemangioma of the neck or upper torso + 1 major criteria or 2 minor criteria, or no hemangioma + 2 major criteria (7) (tab I). On considering these criteria, our patient fit into definitive PHACE syndrome, with the following valid criteria: facial hemangioma > 5 cm in diameter and dysplasia of large cerebral arteries, associated with two cerebral aneurysms.

The cerebrovascular abnormalities in PHACE syndrome. These anomalies are not only the most frequent extracutaneous man-

ifestation, but also the biggest potential source of morbidity, which can lead to the appearance of progressive vessel stenosis with acute ischemic stroke (4, 8). But the highest risk for the acute ischemic stroke is during infancy, between birth and 18 months, period that corresponds also to the cu hemangioma proliferative phase (4). This phase is followed by slow regression (9, 10). In the case of our patient, the cerebral vessels were not stenotic, and the onset was late, at the age of 59, by rupture of aneurysm of right PCoA. Even though within the syndrome isolated venous and cerebral sinus anomalies were reported, the arterial anomalies are the most frequent (7). They can be divided into four subcategories: 1: *dysplasia* (looping, kinking, ectasia or fusiform dilatation); 2: *narrowing* (agenesis, acquired stenosis or occlusion or developmental hypoplasia); 3: *aberrant course or origin of arteries* and 4: *persistence of embryonic anastomose*, and among then arterial dysplasia is the most frequent (7), present also in the case of our patient.

TABLE I.
Major and minor criteria for diagnostic of PHACE syndrome (4)

ORGAN SYSTEM	MAJOR CRITERIA	MINOR CRITERIA
Cerebrovascular	Anomaly of major cerebral arteries ▪ Dysplasia of the large cerebral arteries ▪ Arterial stenosis or occlusion with or without moyamoya collaterals ▪ Absence or moderate to severe hypoplasia of the large cerebral arteries ▪ Aberrant origin or course of the large cerebral arteries ▪ Persistent trigeminal artery ▪ Saccular aneurysms of any cerebral arteries	Persistent embryonic artery other than trigeminal artery ▪ Proatlantal intersegmental artery (types 1 and 2) ▪ Primitive hypoglossal artery ▪ Primitive otic artery
Structural brain	Posterior fossa anomaly ▪ Dandy-Walker complex or unilateral/bilateral cerebellar hypoplasia/dysplasia	Enhancing extra-axial lesion with features consistent with intracranial hemangioma ▪ Midline anomaly ▪ Neuronal migration disorder
Cardiovascular	Aortic arch anomaly ▪ Coarctation of aorta ▪ Aneurysm ▪ Aberrant origin of the subclavian artery with or without a vascular ring	Ventricular septal defect ▪ Right aortic arch (double aortic arch)
Ocular	Posterior segment abnormality ▪ Persistent fetal vasculature (persistent hyperplastic primary vitreous) ▪ Retinal vascular anomalies ▪ Morning Glory disc anomaly ▪ Optic nerve hypoplasia ▪ Peripapillary staphyloma ▪ Coloboma	Anterior segment abnormality ▪ Sclerocornea ▪ Cataract ▪ Coloboma ▪ Microphthalmia
Ventral or midline	Sternal Defect ▪ Sternal cleft ▪ Supraumbilical raphe ▪ Sternal defects	Hypopituitarism ▪ Ectopic thyroid

The facial hemangioma in PHACE syndrome. The studies of facial hemangioma patterns have identified four primary facial segments: segment 1 (frontotemporal region), segment 2 (the maxillary region respecting the nasomedial sulcus), segment 3 (the mandible, chin and lower lip) and segment 4 (the medial frontal scalp, nasal bridge and philtrum) (11). In the case presented, the facial hemangioma was developed at the level of segments 2 and 3. Also, it seems that there is a relation within this syndrome, between the regional distribution of the facial hemangioma and the locations of arterial lesions (12).

Pathophysiology of PHACE syndrome. As for the physiopathology of the disease, based on the observations, Heyer *et al*. (12) have reached the conclusion that the initial vascular changes in PHACE start during the fifth week of embryogenesis, and infantile hemangioma and the cerebral vasculopathy of PHACE seem to be related temporally to an insult that appears in early embryogenesis. To understand the pathophysiological relation between facial hemangioma and cerebral arteries malformations, Burrows *et al.* (13) hypothesized the existence of vascular growth factors or other vascular modulators produced by the hemangioma itself, which would lead to the appearance of the cerebral arteriopathy. These factors that can be secreted during embryonic period of hemangioma formation or during the proliferative phase of hemangioma were well documented (12).

CONCLUSIONS

In the case of our patient, the presence of only a facial hemangioma and the absence of the other cardiovascular, cerebral, ocular or median line anomalies as well as sternal cleft, sternal defects or supraumbilical raphe, allowed the late diagnostic of the cerebral vasculopathy associated with aneurysm rupture. The early diagnostic of the PHACE syndrome is important in following and prevention of the possible complications.

ADVANCES IN ANTIBODY–DRUG CONJUGATES (ADCS) TECHNOLOGY

Antibody–drug conjugates (ADCs) are a potent class of anticancer therapeutics that comprise a high-affinity antibody (Ab) and cytotoxic payload coupled via a suitable linker for selective tumor cell killing. The first FDA-approved ADC was Mylotarg (gemtuzumab ozogamicin) but it was withdrawn from market, due to the acute adverse effects and morbidity in patients, attributed to acid-labile weak hydrazone linkers and nonspecific antigen expression in healthy cells. The limitations and failures of first-generation ADCs were eliminated in second-generation ADCs with the discovery of the breast cancer-targeting ADC, Kadcyla (ado-trastuzumab emtansine) and Adcetris (brentuximab vedotin) (for treating hematological cancer). Despite the improvement in cytotoxic payloads and the introduction of stable linkers, second-generation ADCs have significant limitations in terms of their heterogeneous DAR, resulting from stochastic coupling strategies between the Ab and drug. Efforts are continuing to develop more efficient cytotoxic payloads in third-generation ADCs so that a smaller amount of drug is needed to achieve the desired therapeutic effect and to eliminate drug resistant tumor cells. The development of PBDs, derivatives of tricyclic antibiotics, has attracted interest over other DNA alkylating agents. PBDs are potent compounds, some of which have subpicomolar IC50 and do not show cross-resistance with other chemotherapeutics, such as cisplatin. Four PBD-containing ADCs are currently in clinical trials: SC16LD6.5 is in Phase II trials for small cell lung carcinoma; SGN-CD33A is in Phase II trials for AML; SGN-CD70A is used to treat patients with CD70-positive cancer, and ADCT-301 is in Phase I trials for CD25 lymphoma (Sau S, Alsaab HO, Kashaw SK, Tatiparti K, Iyer AK. NEGATIVE PRESSURE THERAPY IN THE SURGICAL TREATMENT OF DIABETIC FOOT (Abstract) **Aim:** To assess the role of negative pressure therapy in the treatment of diabetic foot by the evaluation of the time required for healing and the functional outcomes of patients. **Material and methods**: Prospective study conducted between September 2014 and February 2017 including 31 patients with diabetic foot clinically monitored following NPWT. Vacuum-assisted closure devices (VAC™ -Hartman) were used for applying negative pressure to the wound according to the specified settings (negative pressure, time of use of a kit) in accordance with patients' outcome. The following were monitored: changes in wound size, their bacterial load, and duration of treatment. **Results:** Healing was obtained in all cases, with an average hospital stay of 27.3 days and 8 days of therapy application. Negative bacterial wound culture results were obtained after an average of 6.45 days by the simultaneous application of negative pressure and antibiotic treatment according to the antibiogram. Skin grafts were necessary to close the defect in 4 cases. **Conclusions:** After the basic wound treatment, auxiliary methods such as negative pressure contribute to healing. In patients with diabetic foot who required surgical intervention, the use of negative pressure therapy yielded a significant benefit in the preservation of the affected limb, after minimal excision. The results obtained throughout our experience recommend the use of NPWT technique as indication for abdominal wall surgery in closing abdominal wall defects, compartment syndrome and surgical site infection after prosthetic mesh. **Keywords:** NEGATIVE PRESSURE, DIABETIC FOOT, TREATMENT.

The first experience with the use of negative pressure wound therapy (NPWT) was reported in 1987 when it was used in the treatment of soft tissue injuries and septic wounds.

Numerous articles were published in the early 1990s and the spectrum of indications was expanded for chronic wounds (leg ulcers, decubitus ulcers). In the early 2000s, a significant extension of indications of this technique applicability was noted in severe dermatological syndromes,

problematic vascular surgery wounds and an increasing use in plastic surgery. In 1993, Fleischmann described a method of wound exposure to sub atmospheric pressure to obtain debridement and wound healing in patients with open fractures. The procedure was improved in Germany by Muller, who applied it to 300 patients with infected wounds, and in 1998 Kovacs et al. described using this technique in the treatment of chronic leg ulcers.

By the application of NPWT in the surgical field in the last 20 years, an innovative approach to treat surgical wound infections was promoted. Due to its benefits, this therapy is currently being introduced widely, becoming the method of choice in some conditions, with favorable results in the treatment of "diabetic foot" wounds, minimizing the surgical gestures and preserving the affected limb.

The overall incidence of amputation ranges from 2.8 to 43.9/100,000 in the general population and from 0.46 to 13.7/1000 patients diagnosed with diabetes (1,2). The proportion of diabetes-related amputations of the total non-traumatic amputations ranges from 40% to 80%, that is a 10-30 times higher frequency than in the general population (1).

The objectives of wound healing are represented by minimizing blood loss, replacement of defects with new tissue (granulation tissue followed by scar tissue) and restoration of an intact epithelial barrier as quick as possible.

Thus, auxiliary therapies, such as ensuring local hyperbaric oxygen atmosphere, administration of growth factors, skin substitutes, grafts of cultivated keratinocytes, electrical stimulation and local drainage, with or without flushing by sealing the wound in negative pressure, may facilitate local healing (2). Increasing blood flow in the circulation and compromised or damaged tissue oxygenation enhance resistance to infection.

Successful wound healing, spontaneous or after surgery is correlated with the bacterial load of the affected tissue which must be less than 10^5 bacteria per gram of tissue. Bacterial accumulations greater than 10^5 interfere with wound healing. The study aims to demonstrate the usefulness of the method and that its clinical use increases the benefits to both patients and medical institution. The objectives of the study were to assess the healing time after negative pressure application, the extent of the surgical procedure and the functional outcomes of the patient.

MATERIAL AND METHODS

The prospective study was conducted on a sample of 31 patients admitted to the Second Surgery Clinic of the “Sf. Spiridon” County Clinical Emergency Hospital from Iasi. The study was conducted between September 2014 and February 2017. Data related to patient demographics, history of the underlying disease, complications and markers of inflammation were used. All wounds were monitored by wound size measurements and photographed to document wound progression.

Laboratory investigations prior to NPWT have included laboratory tests (CBC, markers of infection), X-rays, collection of samples from wound or secretions for antibiogram prior to surgical procedures. The above-mentioned parameters were monitored throughout the treatment period, in accordance with recording data on the duration of NPW, number of surgical debridement at every wound dressing change and used negative pressure values.

Patients were monitored until the wound has completely healed.

Prior to the application of the VAC™ therapy device, the appropriate surgical debridement of all wounds was ensured, followed by wound cleansing through jet lavage irrigation (H_2O_2, betadine and saline).

NPWT dressings have been shaped to fit the wounds, which are then sealed with a semi-permeable film from the kit.

Pressure level was set individually for each patient based on their needs, using continuous suction initially, and then intermittent suction, in the 40 to 110 mmHg range.

Pressure settings depended on the local wound conditions and the pathological conditions of the patient were considered.

Dressing change was performed every 48-72 hours by the treating physician.

RESULTS

The number of admitted patients per study year varied (2014-3 patients, 2015-9 patients, 2016- 18 patients, 1 patient 2017). Demographic data revealed that 18 of the 31study patients were male and 13 females, aged between 38 and 82 years, mean age 65.35 years (67 years in men and 63.07 in women). Sixty-five percent were rural patients.

Sixty-eight percent (21 patients) presented to the Emergency Department and 32% (10 patients) were admitted for various chronic complaints.

The complications of the underlying disease (diabetes mellitus) recorded in the study patients were peripheral neuropathy, vasculopathy, neuropathy, and diabetic retinopathy.

The recorded comorbidities were hypertension, severe anemia and peripheral vascular disease.

Depending on the extent of the surgical procedure underwent by the patients on admission, these were classified as: major and minor. The major ones consisted in the amputation of the leg (6%) and of the thigh (6%), and the minor ones in necrectomy (13%), amputations of fingers with metatarsal head resection (23%); incision, drainage and debridement (29%); anterior foot amputation (23%).

Healing was obtained in all cases to a period of hospitalization that ranged from 5 to 49 days and an average of 27.3 days. The period in which negative pressure therapy was applied in the studied group was between 3 and 16 days.

Dressings were applied for an average of 8.12 days, and dressing changes varied between 48 and 72 hours, with an average of 63 hours.

Wound size at baseline ranged from 7.5 cm^2 to 69 cm^2 with an average of 25.50 cm^2, their closure being achieved after the application of therapy. Antibiogram samples were collected prior to the initiation of treatment and until the closure of the defects, and came back negative after an average of 6.45 days.

The negative pressure used ranged from a minimum of 40 mmHg to a maximum of 110 mmHg, average use 71.61 mmHg, depending on the local wound conditions and considering the pathological characteristics of the patient.

Bridge Technology (multiple aspiration drains) was used in two study patients. In all cases continuous suction was used initially, the device being then set to intermittent suction. In 3 patient's aspiration drainage was associated with local antibiotic-containing instillations (according to the antibiogram), the favorable results being

confirmed by antibiogram. In one case two shifts of the kit were performed and in two cases it took three shifts until the wound could be closed.

DISCUSSION

Loss of sensation in the legs specific to neuropathy combined with poor monitoring can cause any injuries to go unnoticed, to infect, or, in severe cases, amputation (finger or toe) to be the only option left.

The number of diabetes-related amputations has increased successively in 2006-2010, so that 5,827 cases were reported in 2010, 41.32% greater than in 2006 (3).

After the introduction of this method in the treatment of diabetic foot in our clinic a significant reduction of major surgeries by 12% (bellow-knee and thigh amputations) compared to the results obtained by the conventional treatment methods used in 34% of the patients. Of the 311 diabetic patients admitted to our clinic over a 2-year period pre NPWT implementation, 102 patients underwent major surgeries.

Several studies have demonstrated the benefits of NPWT in the treatment of infected wounds, showing superior efficacy compared to conventional dressings (4).

In our study, NPWT was used for a mean duration of 8 day until wound closure or grafting, with an average hospital stay of 27 days, results like those reported by McCallon (4) in cases of diabetic foot, where satisfactory healing was obtained in half the time compared to the control saline gauze group.

The mechanisms of action of NPWT may be quantified for generating micro- and macro deformation to the wound. The reduction in wound size due to the flattening of the pores of the material used and the action of centripetal forces exerted on the entire surface of the wound by the applied sponge determines its macro deformation.

The cells are subjected to various mechanical forces, including the hydrostatic pressure of the extracellular fluid, stretching and compression transmitted over the entire cell array; all these joining the force of gravity determine micro deformations to the wound (5).

Analysis of the above-mentioned elements has shown that the tissue near the sponge structure is subject to compressive forces. In general, the regular but highly variable microenvironment created during this therapy is causing micro deformation. Micro deformations are the morphological result of the integrated mechanics, the shape of the cells being an important determinant of their function (6,7). Furthermore, it is known that cells can adapt to physical stress and thus the functions of some cells can be initiated by physical and dynamic changes.

Angiogenesis is initiated by cell bed micro deformation that causes local hypoxia and thus leads to an increase in the vascular endothelial growth factor (VEGF). The temporary reduction of blood flow to the edges of the wound stimulates angiogenesis through hypoxia-inducible factor (HIF) -1alfa -> VEGF with an increase in density of microcirculation (8-10).

Depending on the underlying pathology, chronic wounds and swelling are often concomitant, the accumulated excess fluids being accepted as a contraventional healing factor by the compressive effect exerted locally on cells and tissues. Applying negative pressure in these situations reduces extracellular fluid accumulation resulting in better blood perfusion by reducing compression on the microvasculature (11).

Toxins, bacteria and exudate may be removed from the wound site along with the fluids (12).

The dressing is impermeable to proteins and microorganisms, thus reducing the risk of wound contamination, and has limited permeability to water vapor and other gases, thus helping to maintain a moist and stable wound environment.

The lack of a wound bed which could allow cell extension and adhesion prevents the development of isometric tension within the cell, thus leading to its spheronization and finally to apoptosis, situation that was not found in chronic wound bed (6).

Before applying NPWT patients were subjected to excisional debridement requiring dressing change twice a day, under surgical stress, maintaining systemic inflammatory response syndrome (SIRS) and an increased risk of septic complications, while the NPWT system allowed a few days between procedures, thereby increasing patient comfort and decreasing hospital costs (time in the operating room, workload, materials) (13).

Microbiological surveillance of the wound after initiation of NPWT was shown to significantly improve the course, with insignificant reduction in the incidence of wound contamination. Clinically, necrosis occurred in a limited number of cases, and the obvious remission of SIRS and hypercatabolic syndrome was observed (14).

Negativizing of antibiogram was obtained in all study patients after an average use of NPWT of 6.45 days, results like those reported in the literature; studies documented decreased bacterial load of the wound in about 20% of patients 4 days after the initiation of NPWT and in 60% of patients 8 days after the initiation of treatment. Studies by Morykwas and Argenta, Banwell et al., and Morykwas et al. have reported increased bacterial clearance in the infected wound by using NPWT.

CONCLUSIONS

In our study, we observed that correct placement of the interface material with adequate wound debridement is essential for the success of NPWT. The application of negative pressure reduces extracellular accumulation of fluid, leading to a better blood perfusion by lowering the compression to the microvasculature and the dressing having limited permeability to water vapor and other gases helps maintain a moist and stable wound environment.

We recommend the use of intermittent suction technique whenever possible because in addition to the physical wound bed changes that lead to an increased bacterial clearance at this level, it also facilitates the association with local instillation of antibiotic. The use of negative pressure not adapted to local conditions can lead to wound bed ischemia.

NEWS

NEW BIOMARKER CANDIDATE IN BREAST CANCER

Researchers from Turkey, Germany, and USA evaluated the role of HLJ1 gene (DNAJB4) in breast cancer progression. This gene belongs to the DNAJ (HSP40) family of heat shocks proteins (HSPs) known as tumour suppressor genes in colon and gastric cancers. It was analysed the HLJ1 *in vivo* and *in vitro* expression and its genetic and epigenetic alterations. HLJ1 expression was found to be reduced or lost in breast cancer cell lines (SK-BR-3, MDA-MB-231, ZR-75-1). In patients with breast cancer, the expression of HLJ1 was less frequent in groups with invasive carcinoma compared with groups with ductal carcinoma *in situ*, benign conditions and normal tissue. Regarding the methylation, the CpG island located in the 5'-flanking region of the HLJ1 gene was found to be methylated in breast cancer cell lines. HLJ1 expression was restored in the ZR-75-1 cell line by DNA demethylating agent 5-Aza-2'-deoxycytidine (5-AzadC) and histone deacetylase inhibitor trichostatin A. Epigenomic mechanisms such as CpG methylation and histone deacetylation might contribute to downregulation of HLJ1 expression. Authors concluded that HLJ1 could be a possible tumour suppressor candidate and potential biomarker for breast cancer. Future epigenomic, functional and clinical studies are needed to assess its potential for biomarker and its role in personalised oncological diagnostic. (Acun T, Doberstein N, Habermann JK, et al. HLJ1 (DNAJB4) Gene is a novel biomarker candidate in breast cancer. *OMICS.* 2017; 21(5):257-265.).

FECAL MICROBIOTA TRANSPLANTATION IN RECURRENT NAP1/B1/027 CLOSTRIDIUM DIFFICILE INFECTION RESISTANT TO VANCOMYCIN AND METRONIDAZOLE IN A PATIENT WITH ULCERATIVE COLITIS: A CASE REPORT

Carmen Monica Preda[1,2]*, Corina Meianu[1,2], Irina Sandra[1,2], G. Becheanu[1,2], Mona Dumbrava[1,2], M. Manuc[1, 2], M. Diculescu[1,2]

FECAL MICROBIOTA TRANSPLANTATION IN RECURRENT NAP1/B1/027 CLOSTRIDIUM DIFFICILE INFECTION RESISTANT TO VANCOMYCIN AND METRONIDAZOLE IN A PATIENT WITH ULCERATIVE COLITIS: A CASE REPORT (Abstract): Most of the studies showed that inflammatory bowel diseases (IBD) patients inflammatory bowel diseases with *Clostridium difficile* infection (CDI) have more of the whole range of short- and long-term worst outcomes than those without CDI. Initial infection with the BI/NAP1/027 epidemic clone was found to be a significant risk factor for relapse. However, current literature is suggesting increasingly that for patients with infections that fail to resolve with traditional antibiotic regimens, FMT's average cure rate of > 90%. We report a case of a 40-year-old man, diagnosed with ulcerative colitis (UC) in 2012 who presented in our clinic for 20 watery stools per day with mucus and blood, hypogastric pain, pyrexia and chills. Rectosigmoidoscopy and histopathological examination diagnosed active lesions of ulcerative colitis with *Clostridium difficile* (*C. difficile*) toxins A/B enzyme immunoassays (EIA) testing initially negative. The patient was non-responder at day 10 of intravenous (iv) corticotherapy and received induction therapy with Infliximab 5mg/kg. EIA testing for *C. difficile* was repeated at day 12 of hospitalization with positive results for toxins A/B, and associated oral therapy with vancomycin and metronidazole was initiated without clinical response in day 7, reasons for what intravenously therapy with tigeciclyne was started with good response. Patient was discharged after 10 days of tigeciclyne, but came back twice for two relapses of *C. difficile* colitis treated successfully with tigeciclyne, reasons for what fecal transplantation was performed in Matei Bals Institute in Bucharest which induced remission of both CDI and UC. **Keywords**: ULCERATIVE COLITIS, *CLOSTRIDIUM DIFFICILE* VANCOMYCIN AND METRONIDAZOLE REZISTANT, TYGECYCLINE, FECAL MICROBIOTA TRANSPLANTATION.

Most of the studies showed that IBD patients with CDI have more of the whole range of short- and long-term worst outcomes than those without CDI. Patients with ulcerative colitis have more severe outcomes than those with Crohn's disease (1). Rates and severity of *Clostridium difficile* infection (CDI) in hospitals in North America and Europe have increased since 2000 and correlate with dissemination of an epidemic strain characterized by higher than usual toxin A and B production, the presence of a

third toxin, binary toxin, and high-level resistance to antibiotics. The strain, which is restriction endonuclease analysis group BI, pulse-field gel electrophoresis type NAP1, and polymerase chain reaction ribotype027, is designated BI/NAP1/027(2, 3, 4). One of the most problematic aspects of CDI is the propensity of recurrence in 15% to 35% of patients who initially respond to antimicrobial therapy. In addition, recurrent CDI is difficult to treat and contributes to significant morbidity and mortality and increased health care expenditures (5). Initial infection with the BI/NAP1/027 epidemic clone was found to be a significant risk factor for relapse (6).

CASE REPORT

A 40-year-old man was admitted in our department in May 2014 for 20 watery stools per day with mucus and blood, hypogastric pain, pyrexia and chills. His medical history includes chronic hepatitis B infection in treatment with entecavir 0.5mg per day and UC diagnosed in 2012, in treatment with azathioprine at a dose of 150 mg per day (2,5 mg/kg). He confessed cessation of smoking for one year, previously being a chronic smoker of 20 cigarettes per day. Should be mentioned in his medical history multiple flares of UC since diagnosis due to low-compliance to medication, also self-discontinuation of azathioprine 2 weeks before hospital admission because of lack of money. At clinical examination, the patient was apyretic, underweight with a BMI of 17.5kg/m^2 with skin and mucosal pallor, tachycardia and with tenderness in lower abdomen with palpation. Laboratory tests showed moderate leukocytosis, important increase in C-reactive protein levels and hypochromic microcytic anemia. Stool test were negative for infections. *Clostridium difficile (C. difficile)* toxins A/B enzyme immunoassays (EIA) tested negative.

Rectosigmoidoscopy revealed absent vascular pattern, edema, erythema, friability of the mucosa and erosions (fig. 1).

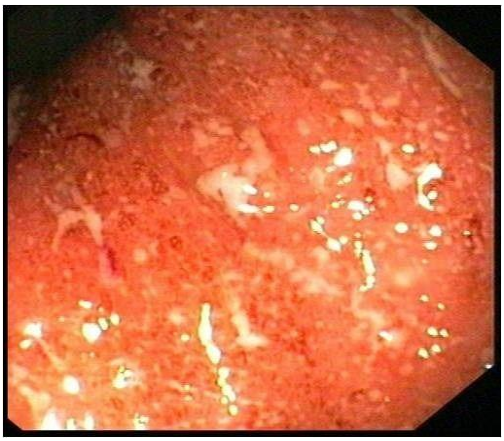

Fig. 1. Colonoscopy image showing continuous lesions of edema, erythema and friability on 60 cm of the colonic mucosa explored.

Histopathological examination showed diffuse chronic mucosal inflammation, cryptitis, regenerating epithelium with erosion and superficial fibrino-leukocytic exudate, HE, 200x (fig. 2).

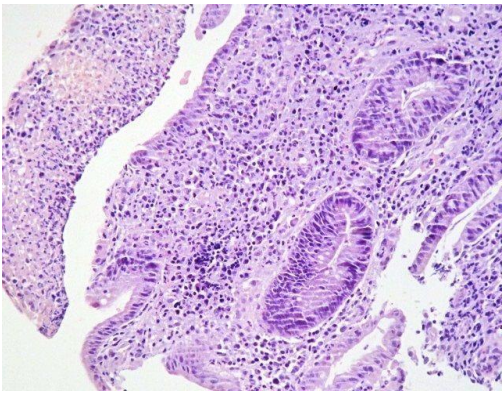

Fig. 2. Examination of biopsy specimens of inflamed colonic mucosa.

The severity of UC flare was framed in a Mayo score of 12 points. The patient received intravenous (i.v.) corticotherapy with lack of response at day 10. First induction dose of infliximab 5 mg/kg was administered with the maintenance of oral corticotherapy. EIA testing for *C. difficile* was repeated at day 12 of hospitalization with positive results for toxins A/B. We decided to stop further administration of infliximab and start tapering corticotherapy until *C. difficile* eradication. We initiated oral vancomycin 1,000 mg per day in association with oral Metronidazole 1,500 mg per day and *Saccharomyces boulardii* capsules 500 mg per day. After three days, the patient developed digestive intolerance with vomiting and the regimen was changed to iv metronidazole 1,500 mg/day. At day ten of treatment the patient had a decrease in the number of stools (9 per day, with no blood but with the presence of pus), still with persistent abdominal pain. Blood tests showed no modification regarding inflammatory panel with increased values in serological inflammatory markers, severe hypochromic microcytic anemia that required blood transfusions and severe hypoalbuminemia. Fecal cytology showed the presence of leukocytes.

Nucleic acid amplification test (NAAT) for *C. difficile* toxin genes was positive for hipervirulent NAP1/B1/027 strain. Oral vancomycin was continued with increased dosage 2,000 mg per day (500 mg every 6 hours) in association with vancomycin enemas 500 mg four times per day. After ten days of previous regimen due to lack of response we added tigecycline 50 mg every 12 hours intra-venously for 16 days with clinical response consisted in normalization in the frequency and consistency of stools. The patient was discharged from hospital with the recommendation to continue vancomycin in a tapering regimen 250mg four times daily with halving doses weekly until 125 mg every other day for 7 days in association with *Saccharomyces boulardii* capsules 500 mg per day. Oral corticotherapy tapering was continued. After one month, the patient was re-admitted to the hospital for the recurrence of watery bloody stools and severe abdominal pain. We performed EIA retesting for *C. difficile* which was positive for both toxins A and B and fecal cytology which showed the presence of leukocytes. Patient received a second course of intravenous tygecicline 50 mg every 12 hours with favorable evolution and the normalization of stools at day 7. At two weeks follow up the patient presented with the second relapse of *C. difficile* colitis and again was treated with tygecicline in association with oral metronidazole, oral vancomycin and *Saccharomyces boulardii* capsules with favorable evolution. After this third recurrence of *C. difficile* infection patient received fecal microbiota transplantation (FMT) in Matei Bals Institute in Bucharest with a donor from the personal of the Hospital, through a naso-gastric tube. One month after, the patient had a fourth recurrence of *C. difficile* colitis meeting the same pattern as the previous and we performed a second procedure of FMT (changing the donor with one person from the patient's village). At further follow-ups for a period of 2 years the patient was in clinical remission of IBD with the normalization of clinical examination, weight gain and with normal range for serological inflammatory markers, on maintenance therapy with oral 5-ASA 3 g/day.

DISCUSSION

The endoscopic finding of pseudo membranes found in 50% of *C. difficile* infected patients (per data from last decade) is less common (13%) in IBD patients with CDI (7) and our case had also an endoscopic aspect of ulcerative colitis flare. A strong pre-test suspicion for CDI (as in our case watery diarrhea, severe hypoalbuminemia, severe anemia, severe acute inflammatory syndrome), empiric therapy for CDI should be considered regardless of the laboratory testing result, as the negative predictive values for CDI are insufficiently high to exclude disease in these patients (8). In our patient, the clinical presentation of *C. difficile* colitis mimic an underlying IBD flare and the first test for toxins in the stool was negative, and that made us to escalate the immunosuppressive therapy that lead to a very severe evolution of this patient. Toxins A+B EIA testing commonly used as first diagnosis test for CDI has a sensitivity of single sample testing low (72%) and may increase by 10% with second stool testing (84%). Three sample testing increase sensitivity to 86% (8). Currently, standard recommendations for treatment of mild CDI include metronidazole or vancomycin, with data suggesting that vancomycin is more efficacious than metronidazole in severe CDI (1). This is the first Romanian report of a case of *C. difficile* colitis with the BI/NAP1/027 strain in a patient with UC, community acquired. Rafila et al (9) report in their study that PCR ribotype 027 was found to be the most dominant type in CDI in Bucharest, accounting for 68% of the Romanian isolates during 2011-2012, 84% healthcare associated and 16% community acquired. Now we report resistance of this strain to metronidazole or vancomycin and a good response to tigeciclyne therapy, which practically saved the life of this patient. We think that Infliximab worsened the evolution of CDI in our patient, our point of view differs from Seicean A et al (10).

CONCLUSIONS

Our case emphasizes the need for FMT use as a promising rescue therapy for refractory IBD and CDI. FMT was indicated because of repeated relapses of *C. difficile* colitis, as suggested by current data from the literature. FMT practically cured both diseases, with the condition of a good quality donor and the brief protocol of patient preparation before and during FMT.

ACKNOWLEDGEMENTS

Dr. Camelia Ghita from the Epidemiology Department, Clinic Fundeni Institute, Bucharest for his support in establishing a correct diagnosis and therapy in this case and Dr. Catalin Apostolescu from the Infectious Disease Department, "Matei Bals" Institute, Bucharest who performed the fecal microbiota transplantation.

INTRADUCTAL TUBULOPAPILLARY NEOPLASM OF THE PANCREAS: AN UPDATE FROM A PATHOLOGIST'S PERSPECTIVE

The intraductal neoplasms of the pancreas are defined by the current 4th edition of the World Health Organization (WHO) classification as macroscopic epithelial neoplasms with ductal differentiation that grow in the pancreatic ductal system. The 2 entities included in this category are intraductal papillary mucinous neoplasm (IPMN) and intraductal tubulopapillary neoplasm (ITPN). Before the current WHO classification, intraductal neoplasms of the pancreas were classified into 3 groups: IPMN, pancreatic intraepithelial neoplasia (PanIN), and intraductal tubular neoplasm. Both IPMN and ITPN can be either cystic or solid-mass forming. The distinction between the intraductal neoplasms and PanIN is that PanIN is microscopic. On the contrary, by definition, both IPMN and ITPN are grossly and radiographically detectable lesions with an arbitrary minimal size criterion of 1 cm. As these neoplams are considered to be precursor lesions to carcinomas, surgery and close clinical follow-up is generally recommended. Morphologically, they can mimic some subtypes of IPMN. However, molecular studies revealed that they are distinct entities. Further studies are needed to elucidate the clinical, pathologic, and molecular features of ITPN, which could be used as guidance for the management of patients (Rooney SL and Shi J. Intraductal Tubulopapillary Neoplasm of the Pancreas: An Update from a Pathologist's Perspective. *Archives of Pathology & Laboratory Medicine* 2016; 140 (10): 1068-1073).

UNEXPECTED CORONARY THROMBOSIS INDUCED BY ANTIPHOSPHOLIPID SYNDROME (HUGHES SYNDROME) - CASE REPORT (Abstract): Antiphospholipid syndrome (APS), one of the most common states of acquired hypercoagulability, is diagnosed by the persistent presence of antiphospholipid antibodies and recurrent episodes of vascular thrombosis. We present the case of a 39-year-old man late-presenting for cardiac rehabilitation treatment after primary percutaneous coronary intervention (PCI) performed for anteroseptal myocardial infarction. He was a nonsmoker, with no prior personal history of other cardiovascular diseases (CVD) or cardiometabolic syndrome. The 60% thrombotic occlusion of the left anterior descending artery (LAD) leading to the acute cardiac event was the only abnormality that was found. The only etiological explanation was the late measurement and the positive tests for antiphospholipid antibodies. In young patients with no history of thrombotic disorder, such as cancer, cardiovascular or metabolic diseases, the unexpected onset of myocardial infarction by thrombotic coronary occlusion can be attributed to silent, undiagnosed autoimmune condition.
Keywords: ANTIPHOSPHOLIPID SYNDROME, MYOCARDIAL INFARCTION, ANTIPHOSPHOLIPID ANTIBODIES, AUTOIMMIUNE DISEASES.

Antiphospholipid syndrome (APS), also known as Hughes syndrome (1), is an autoimmune disorder and represents an acquired hypercoagulable state. It is characterized by vascular thromboses or pregnancy morbidity, such as fetal loss, and it occurs in patients who have persistent antiphospholipid (aPL) antibodies (2). As aPLs have been a hallmark feature of APS for almost half a century, aPLs detection is the first-line approach for diagnosing the APS. Per 2006 revised APS classification criteria (3), the diagnosis of APS requires the persistent presence of at least one of the following aPLs, including lupus anticoagulant (LA), immunoglobulin G (IgG) and/or immunoglobulin M (IgM) anti-cardiolipin (aCL) antibodies, and IgG and/or IgM anti-β2 glycoprotein 1 (aβ2GP1) antibodies. Immunoglobulin A (IgA) aCL and IgA aβ2GP1 antibodies are not currently included in the laboratory criteria for APS, but are suggested as "noncriteria" antibodies for seronegative patients with clinical suspicion of APS (4, 5).

CASE REPORT

A 39-year-old male presented for cardi-

ac rehabilitation program after coronary artery revascularization surgery. The patient had positive family history of cardiovascular diseases (CVD), but no personal history of other cardiovascular conditions or cardiometabolic syndrome. He was a nonsmoker. Physical examination revealed a status of anxiety, tachycardia, and mild dyspnea. Blood test showed complete blood count within normal values, with a slightly elevated erythrocyte sedimentation rate (ESR) (normal values for men < 50 years: 0-15 mm/hour), normal levels of lipid profile, fasting blood sugar (FBS) and glycated hemoglobin (HbA1c) indicating a good short-term and long-term control of blood sugar levels. Kidney function, liver function and hydro-electrolytic balance were normal. On admission, the only abnormal findings were the biological markers for myocardial necrosis - CPK 210 U/L, CK-MB 19.3 U/L and Troponin T 2.03 ng/ml. Resting electrocardiogram (ECG) revealed ST segment elevation in anteroseptal precordial leads (V1-V4) (fig. 1). Apart from ST elevation, a pathological Q wave (0.06 seconds wide, and a depth > ¼ height of R-wave it precedes) in V1-V3 precordial leads. Heart rhythm was regular, but on sinus tachycardia of around 110 beats per minute. The normal electric heart axis (QRS axis) was preserved.

Coronarography angiography showed no injury to the left main artery (LM) and left circumflex coronary artery (LCX), but revealed a 60% thrombotic occlusion of the left anterior descending artery (LAD) (fig. 2).

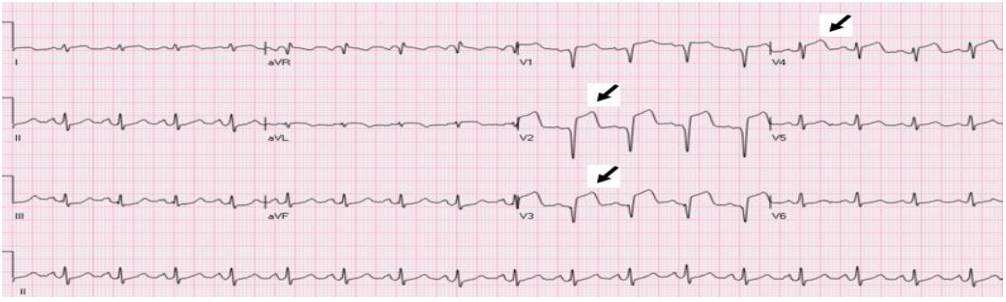

Fig. 1. ECG - anteroseptal ST segment elevation myocardial infarction

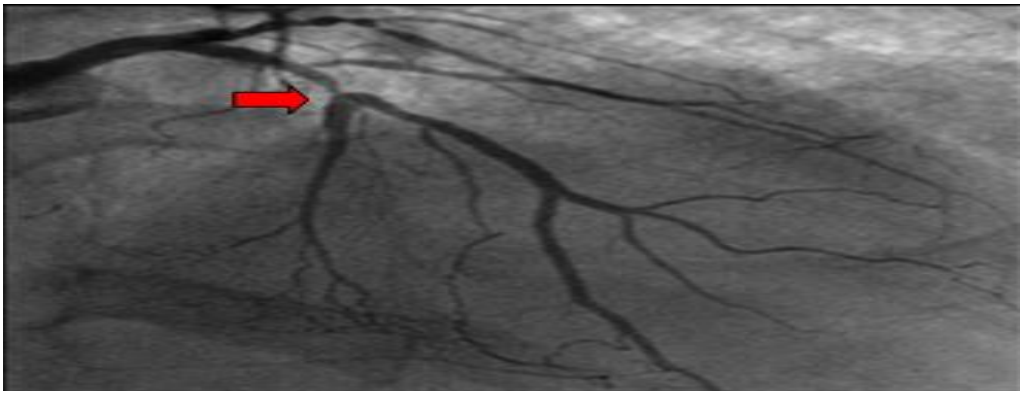

Fig. 2. Coronary image of 60% LAD obstruction

Two months later the patient presented for cardiac rehabilitation program. Clinical assessment on admission to the rehabilitation clinic showed: normal weight (body mass index 24 kg/m²), resting blood pressure (BP) of 100/55 mmHg and heart rate of 70 beats per minute. Dyspnea was the only remaining physical symptom. The 24-hour continuous BP monitoring revealed normal BP levels and normal dipper profile. The 2D transthoracic Doppler echocardiography showed mild tricuspid regurgitation, mild mitral regurgitation, hypokinesis of the basal segment of the interventricular septum, and apical akinesis of the anterior wall. Resting electrocardiogram showed chronic anteroseptal myocardial infarction (fig. 3).

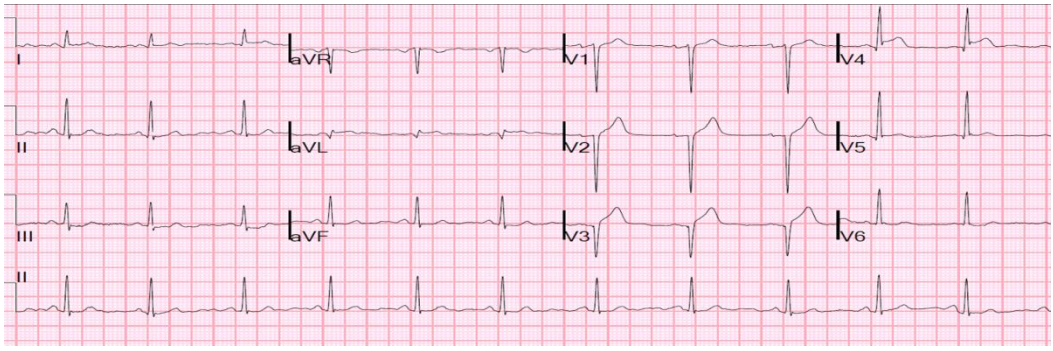

Fig. 3. ECG with appearance of chronic anteroseptal myocardial infarction

Laboratory test values during cardiac rehabilitation program showed normal red blood cell count; liver and kidney functions were normal as well, cholesterol parameters, sodium and potassium levels were within normal ranges. The immunology report revealed the presence of LA (lupus antibody) and aCL (anticardiolipin antibody) IgG 88 GPL/mL (IgG > 40 phospholipid units (GPL)/mL), aCL Ig M 100 MPL/mL (Ig M >99 phospholipid units (MPL)/mL).

DISCUSSION

Antiphospholipid syndrome comprises a heterogeneous group of autoimmune diseases. These conditions are characterized by recurrent arterial or venous thrombosis, or both, and/or pregnancy morbidity, as well as by the presence of aPL antibodies. APS is classified as primary or APS associated to other diseases. Primary APS (PAPS) is defined by the presence of aPL antibodies, but no evidence of any underlying systemic autoimmune disorder (6).

In our case, a relatively young patient with no personal risk factors for myocardial infarction, we thought that an autoimmune disease could be responsible for the coronary thrombosis. The positive antiphospholipid antibodies supported the diagnosis of antiphospholipid antibodies syndrome.

The clinical diagnosis of APS is supported by the laboratory findings, as the main clinical features of thrombosis and pregnancy morbidity also occur in many other diseases. In clinical settings, the standard enzyme-linked immunosorbent assay (ELISA) gives a large variation in antibody positivity, because there are no standardized kits. Studies conducted on the compared to commercial ELISAs showed similar performance and results between laboratories in detecting IgG/IgM aCL and IgG/IgM aβ2GP1 autoantibodies (7-12).

As for cardiac manifestations in APS, they may range from pulmonary hypertension, intracardiac thrombosis, to dilated cardiomyopathy, coronary artery disease and valvular heart disease (13-15). Although coronary artery disease and restenosis following percutaneous coronary intervention (PCI) are less common, the risk of their occurrence is increased in APS patients compared to other conditions. The pathophysiological explanation for the fact that APS patients are predisposed to stent thrombosis resides on APS predilection for thrombotic events. In addition, unresponsiveness to aspirin and clopidogrel can predict the risk of stent thrombosis (16).

As in adults and elderly, in young adults' atherosclerosis is the main cause of coronary events. Other causes of coronary heart disease are related in about 20% of cases to nonatherosclerotic factors - such as autoimmune diseases, connective tissue disorders, or coronary abnormalities. However, cases of systemic lupus erythematosus (SLE) and antiphospholipid syndrome (APS) may present different onset clinical manifestations. In SLE, there are no age-based differences regarding the prevalence of myocardial infarction; conversely, this major coronary event is unusual in APS and it might appear during the progression of the antiphospholipid syndrome.

The phenotypes of vascular damage in APS are characterized by the strong interactions between circulating aPL and cell surface molecules of target cells, primarily endothelial cells and platelets. The molecular basis of APS is still largely unknown. Endothelial cells produce nitric oxide, factor that promotes vascular health by regulating the physiological processes (thrombosis, endothelial-leukocyte interaction, vascular cell migration), and by modulating the vascular tone.

In all young patients with cerebral infarction, myocardial infarction, pulmonary embolism, recurrent miscarriages, and unexplained low platelet count, the high likelihood of antiphospholipid antibody syndrome should be considered. Among the form of APS associated to other diseases are various systemic autoimmune syndromes, especially systemic lupus erythematosus (SLE) (17).

CONCLUSIONS

This case highlights the importance of considering in the emergency department the prothrombotic states, such as SLE and APS, in adult patients with no prior cardiovascular risk factors presenting with acute myocardial infarction due to unexplained intracoronary thrombosis.

Early diagnosis of catastrophic APS and aggressive therapies are essential to help such patients from succumbing to this potentially fatal condition.

This syndrome should be suspected more frequently in all young patients than in adult patients, especially if they do not present any cardiovascular diseases and develop myocardial infarction.

EFFICIENCY OF TREATMENT FOR FEMALE STRESS URINARY INCONTINENCE USING THE TENSION-FREE VAGINAL TAPE OBTURATOR TECHNIQUE (Abstract): **Aims**: The modern *Tension-Free Vaginal Tape Obturator* (TVT-O®) technique is used worldwide to treat *Stress Urinary Incontinence* **(**SUI). The subject of the paper is timely and with a major practical potential. The paper presents an ample retrospective study on a series of patients hospitalized at the Second Clinic of Obstetrics-Gynecology of "Cuza-Vodă" Obstetrics and Gynecology Clinical Hospital from Iasi, for a period of 3 years. In the period January 2010–January 2012, 164 female patients were subjected to surgical procedures to treat type II SUI, inserting TVT-O® tapes. **Material and methods**: Patients were selected based on anamnesis, clinical examination and positive Bonney's test. When genital prolapse was associated with SUI, simultaneous with strip insertion, other interventions were practiced, too. Cases were followed in the immediate postoperative period, at 2 months, 6 months and 1 year, in order to analyze the efficiency of the method. 164 female patients aged between 38 and 65 were included in the study, of which 60 cases had isolated SUI and in 104 of the cases SUI was associated with genital prolapse. **Results**: In 85% of the cases, the healing rate was satisfactory, and in 15% of the cases, it was partially satisfactory, keeping the percentage at 6 months and 1 year. In respect of complications at 16 female patients, SUI was improved, but persistent, in 14 cases the mictional necessity was described as absent before intervention; in these cases, we used oxybutynin, in 4 of them-tape sectioning and in 4 cases the exteriorization of the tape was relieved after 2 months, performing the secondary vaginal suture. The simple operatory technique, the reduced hospitalization period, the short convalescence and the immediate results support the TVT-O® procedure in the treatment of SUI. Postoperative complications are rare and do not compromise results. The main goal of *"Sling"* interventions is the creation of a reliable closure mechanism, supporting the passive urinary retention by urethral compression. **Conclusions**: Our point of view with regard to the controversy of using TVT-O® tapes is that the technique does not have to be abandoned, being extremely efficient in academic centers with ultra-specialized staff.
Keywords: STRESS URINARY INCONTINENCE, TVT-O®, TAPE, MICTIONAL IMPERIOSITY, DETRUSOR DYSSYNERGIA.

Urinary incontinence (UI) is a condition that seems to affect up to a quarter of the women over 45 years-old, causing discomfort or even a high level of severity.

Over time, UI was considered a consequence of the anatomic changes determined by births or great physical effort, being seen as a symptom of pelvic organ prolapse. UI is produced by the association of anatomic causes with a series of factors that determine disorders of the bladder and urethra. Thus, we can speak of an anatomic type of UI or a "functional" UI, and a mixed UI. In conclusion, we can distinguish SUI (stress urinary incontinence) caused by morpho-functional changes caused especially by parturition ("anatomic" UI) and "functional" UI based on the presence of involuntary contractions of the detrusor in the bladder filling phase. By definition, SUI is described as an involuntary urine loss generated by physical effort in the absence of the contraction of the detrusor muscle. It emerges during intra-abdominal pressure increase, when intra-bladder pressure increase and exceeds urethral closing pressure, having an intermittent character.

Though urinary incontinence does not endanger the patient's life, it is a state that strongly affects physical, psychological and social wellbeing, thus affecting the quality of life.

Though using the TVT (tension-free vaginal tape) technique, the cure rates have been satisfactory, in 2001, Delorme et al. (1) proposed a trans obturator approach with the purpose of reducing significantly intraoperative complications.

Different surgical and non-surgical techniques have been adopted in the treatment of urinary incontinence for the past years, and the management principles have changed along with the introduction of new and less invasive techniques.

Starting 1913, when Howard Kelly et al. (2) described his first anterior plication stitch until today, several authors have proposed over 200 surgical approaches for the treatment of stress urinary incontinence. Although different treatment schemes have been proposed, the ones based on surgery remain the main treatment.

The Marshall Krantz procedure and the Burch urethropexy were the first surgical techniques using suprapubic approaches to elevate the paraurethral tissues to the Cooper's ligament or the pubic periosteum (3).

Though these techniques were considered in the past the golden standard, with high cure rates during the first postoperative year in comparison to the Kelly procedure, many physicians tried to bring a surplus to these techniques in order to reduce the hospitalization period, morbidity and postoperative complications (4).

Petros and Ulmstein, through the integral theory of female urinary incontinence by means of mid-urethral support stirred an actual medical revolution, with this theory leading to the TVT technique development towards the end of 1990, and a few years later Delorme E. proposed the TOT (transobturator tape) method.

The advantage of this procedure is the fact that it excludes the need for intraoperative cystoscopy and avoids the retro pubic area, thus excluding the risk of bowel perforation or vessel lesion.

The TVT procedure resembles the TOT, with a different technique to insert the tape, but no difference has been reported regarding the cure rate. The techniques can be compared as regards the patients' satisfaction a year after surgery. Several studies reveal the fact that the TOT can reduce significant postoperative complications (5).

MATERIAL AND METHODS

The collection, processing and interpretation of the information necessary for the study led to knowledge on the particularities of the stress urinary incontinence cases hospitalized in the 2nd Clinic of Obstetrics and Gynecology of "Cuza-Vodă" Obstetrics and Gynecology Clinical Hospital from Iasi, between January 2010 and January 2013, by using the data recorded in the observation charts and the computerized system. This study is a retrospective analysis on all cases of operated stress urinary incontinence type II, in which TVT-O® tapes were inserted.

Between 2010 and 2013, 164 cases of SUI were diagnosed and investigated, and patients were selected based on their anamnesis, clinical examination and positive Bonney test (6).

Stress urinary incontinence was classified depending on the degree of stress causing it, namely: 1st degree – incontinence emerges only under high stress, 2nd degree – incontinence emerges under moderate stress, such as walking down and up the stairs, 3rd degree – incontinence emerges under low stress such as orthostatic, the patient being continent in clinostatism. The Bonney test is performed by the exploring physician with the middle finger and forefinger placed on either side of the urethra, ascending the urethra-bladder junction without compressing it. This test enables the differentiation between stress urinary incontinence and the detrusor dissinergy and it is positive when urine loss disappears during the test performance.

The data collected as a study material and considered refer to: the total number of cases of urinary incontinence type II investigated, diagnosed and operated, the annual distribution of the disease cases, the repartition of cases according to age groups, personal physiologic history (menstrual status, parity) and pathological history, the duration of the surgical intervention, the duration of hospitalization, the postoperative antibiotic treatment, postoperative complications.

The insertion of the TVT-O® (*tension free vaginal tape obturator*) tape was a sole operation or associated with other interventions for the correction of the associated genital prolapse. The efficiency of this technique was evaluated immediately after surgery, after 2 month, 6 months, and 12 months.

The study included operated patients with SUI type II who underwent the insertion of TVT-O® tape and who came for postoperative check-up after 2, 6, and 12 months, and excluded patients who did not come back for postoperative check-ups (31.7% of the total).

RESULTS

Following the processing and evaluation of the 164 cases of stress urinary incontinence operated, recorded in the 2nd Clinic of Obstetrics and Gynecology of "Cuza-Vodă" Obstetrics and Gynecology Clinical Hospital from Iasi, between 2010 and 2013, we should mention that from the point of view of the temporal variable, a maximum number of cases was in 2012, with 66 cases recorded (40.24% of the total), and the fewest were recorded in 2010.

Our study revealed that the average age of the patients diagnosed with SUI type II is 53 years, and the patients included in the study were between 38 and 65 years old.

Most hospitalizations (78.3% of the total) were persons over 50 years-old, which is associated with the "enrichment" of the morbid status with age.

The estrogens deficit generates a decrease in the capacity of proximal closure of the urethra, microbial colonization manifest-

ed clinically by dysuria, polakiuria, and urethral atrophy leads to the shortening of the urethra, the disappearance of the bladder-urethral angle and the emergence of an ectropion of the urethra mucous membrane, eventually favoring stress urinary incontinence. From the point of view of the menstrual status, 59.75% of the total women included in the study were menopausal and 40.24% of the total had genital activity.

During labor, direct lesions are generated to the soft pelvic tissues and partial denervation of the pelvic floor. The dilacerations of the connections between vagina, urethra and bladder produced by excessive distension, together with the production of cortisol and progesterone during pregnancy lead to the laxity of the fascial supporting structures and therefore cause the decrease in intraurethral pressure and an increase in the mobility of the urethra. Our study did not include any nulliparous patients, 46 women (28.05%) of the cases were primarae and 118 women (71.95%) were multiparae. Obesity and the high body mass index represent a risk factor for SUI, and patients can improve incontinence by losing weight. A comparison was made between the TOT efficiency and safety from the weight point of view (weight excess and normal weight). Patients were divided depending on their body mass index into 3 batches: batch X with normal weight (BMI<25 kg/m^2), batch Y with overweight (BMI 25-30 kg/m^2) and batch Z with obesity (BMI>30 kg/m^2). The study revealed a BMI between 19 and 48kg/m^2, with an average of 28.5 kg/m^2. Of the 164 patients, batch X with BMI<25 kg/m^2 represents 26.8% of the total (44 patients), batch Y with BMI 25-30 kg/m^2 includes 79 patients (48.2% of the total), and batch Z includes women with BMI>30 kg/m^2, namely 41 patients (25%) (tab. I, fig.1).

No. of patients	44	79	41

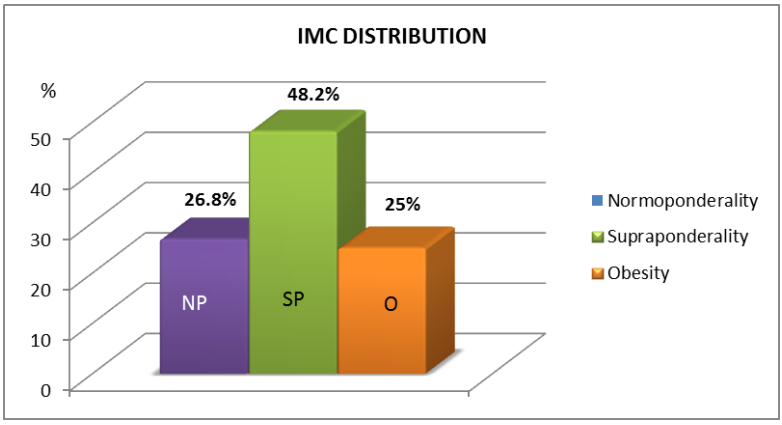

Fig. 1. Distribution of cases in the three batches: X, Y and Z

From the point of view of the associated conditions, 48 patients (29.3% of the total number of patients included in the study) had associated pathology: 5 patients had angina pectoris, 12 suffered from high blood pressure, 22 had chronic venous insufficiency, 15 had dyslipidemia, 3 had hypothyroid and 2 had left renal lithiasis (fig. 2).

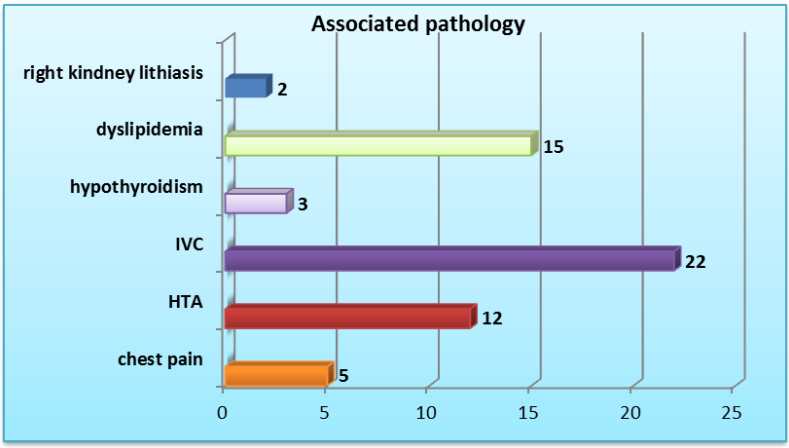

Fig. 2. Distribution depending on the associated pathology

We found isolated SUI in 60 cases, genital prolapsed associated with UI in 63.41%. Of the 104 patients, rectocele was associated in 89 (85.58%), cystocele 11 (10.58%), and both cystocele and rectocele in 4 patients (3.84%) (fig. 3).

The duration of surgery varied between 20 minutes and 1 hour and 20 minutes, with an average of 35 minutes.

The insertion of the TVT-O® tape was a sole operation in 37.8% of the cases, namely in 62 patients, and in 62.2%, namely 102 patients, anterior colpoperineorraphy was associated with posterior colpoperineoraphy, myorhaphy anal levators and right labial cystectomy (3 cases).

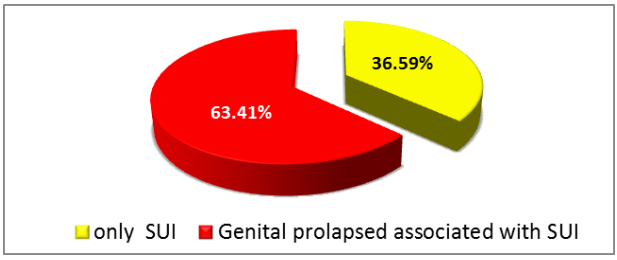

Fig. 3. Stress urinary incontinence associated or not with genital prolapsed

From the anesthetic point of view, general anesthesia was performed with orotracheal intubation in 25 (15.24%) patients' general anesthesia using the larynx mask in 17 (10.37%) and rachianesthesia in 64 (74.4%) patients.

The average hospitalization time was 3.75 days, between 2 and 7 days.

In our study, the cure rate was 85% satisfactory and 15% partially satisfactory, after 2 months as well as after 6 months and 12 months.

52 (31.7%) of the 164 patients did not come for postoperative check-ups, therefore only 112 patients – 68.3% - were monitored immediately, after 2 months, 6 months and 12 months. As regards complications, 16 (14.28%) had improved but persistent SUI, 14 (12.5%) experienced previously inexistent imperious need to urinate (prosthesis positioned too tightly), which were treated with Oxybutynin or by sectioning the prosthesis in 4 cases, and in other 4 cases of prosthesis exteriorization in the check-up after 2 months after surgery, for which a secondary vaginal suture was performed.

The bladder voiding dysfunction after surgery for incontinence is a possible complication of all procedures treating SUI. The avoiding dysfunction term indicates the term of obstructive uropathie until the full urinary retention and includes irritative symptoms such as hyperactivity of the detrusor or imperious need to urinate de novo.

The impossibility of storing urine is determined mainly by the hyperactivity of the detrusor muscle. There are basic theories of this hyper reactivity that include hypersensitivity acquired through the parasympathetic denervation produced by the obstruction of the urinary bladder, denervation produced by surgical dissection regardless of the voiding obstruction. The voiding impossibility is given mainly by the obstructive voiding of the urinary bladder determined by the increased pressure generated by urethral compression. The sutures placed too medially and therefore too close to the urethra can lead to urethral deviation or periurethral scars.

Among postoperative complications, there were three cases of allergic reaction to Ciprinol, in which the antibiotic was replaced with Gentamicin based on prior testing, and 1 case of urine loss upon suppression of the urinary probe, which was corrected with Oxybutynin (Driptane) the second postoperative day.

DISCUSSION

In order to establish the individual statistical risk for every woman of developing SUI, a rigorous evaluation of all health problems that she can have (or has) is necessary. Other factors, such as obesity, parity, hormonal status, can be risk factors for SUI.

A large number of long-term studies are necessary to establish the efficacy of the transobturator tape in comparison to the TVT technique. Trying to define the cure rates of this surgical procedure, Novara et al. say in a systematic analysis of literature that patients treated by the TOT technique had slightly lower rates of complications than the ones treated by the TVT method, with a significantly low risk of vagina perforations.

Our study revealed that the TVT-O® technique was as safe and efficient in treating SUI, regardless of the body mass index. After surgery, life quality improved the same way for each patient, regardless of the batch to which she belonged, depending on weight. There were no significant differences as regards complications. Our study revealed a BMI between 19 and 48 kg/m^2, with an average of 28.5 kg/m^2. The 164 patients were divided into 3 batches, X, Y and Z, respectively, with normal weight, overweight and obese, with the highest percentage in batch Y, with a BMI

between 25 and 30 kg/m^2, representing overweight.

Most hospitalizations were of persons over 50, which is associated with the "enrichment" of the morbid status that comes with age. Our study revealed that the average age of patients diagnosed with SUI type II is 53 years-old.

56.76% of the 164 women included in the study were menopausal and 40.24% cases had genital activity.

Adding the TVT-O® intervention during the anterior prolapse correction seems to convey higher durability to the correction resulting in the long run in a lower rate of the urinary symptoms and a better life quality in comparison to isolated anterior colporraphy. Isolated SUI was found in 60 cases, genital prolapsed associated to SUI in 63.41% of the total number of patients.

Moreover, in subsequent postoperative consultations, no patient had increased body mass index and no patient was susceptible of recurrent SUI, which contradicted the literature results of studies on incontinence surgery in obese patients (7).

In comparison to the literature data, patients were monitored for 29 months and the cure rate was 78.8%, in what concerns our study, the cure rate is slightly higher-85%- but the monitoring period in our study was 12 months.

The absence of intraoperative complications is in accordance with the literature data. As for postoperative complications, specialized literature reports 11.2%, and in our study postoperative complications were 25% (8).

Abdel-Fattah et al. (9) did a secondary analysis, in a randomized study on women who had any type of surgical intervention for SUI and showed that TOT had a good success rate (he referred to a success rate and a cure rate of 69.6 and 76.5% respectively, but there were no significant differences in the cure rates for the insertion of the tape through the obturator hole from the outside to inside and from the inside to outside).

Based on their report regarding the data available in the two randomized clinical studies, Novara et al. (10) could not demonstrate any significant difference between TVT-O and TOT.

In a randomized multi-centric study done in 2007, Porena et al. (11): 148 women, of which 73 underwent TVT and 75 underwent TOT, concluding that both surgical approaches were as safe, without significant ongoing differences of the intra- and postoperative complications during the 2-year monitoring period.

Another element to be discussed is the urodynamic tests. As regards our study, preoperative urodynamic exploration was not performed, which is a disadvantage, because this exploration could help in selecting cases more efficiently and in increasing the patients' satisfaction degree.

CONCLUSIONS

Our study data demonstrate that the TVT-O® procedure is safe and effective and that the body mass index did not influence the result during 12 month (in which the patients included in the study were monitored) and does not have contraindications for continent surgery.

The treatment for SUI has undergone revolutionary improvement for the past 15 years. The transobturator techniques either from the inside to outside or from the outside to inside have been proposed this past decade precisely to minimize complications.

As regards the cure rate, both proce-

dures –TOT and TVT-O®– improved women's quality of life and have almost equal cure rates.

The TVT-O® surgical technique is a minimally invasive procedure characterized by simplicity, reduced hospitalization, short convalescence period, and immediate results. Intraoperative complications are absent and postoperative complications are few and solving them does not compromise the continence results.

The main purpose of the *"Sling"* intervention is to create a certain closing mechanism helping in the passive retention of urine by compressing the urethra.

Important randomized clinical studies with a longer monitoring period related to the said techniques are necessary to establish exactly the efficacy and safety of the said minimally invasive technique.

BILATERAL BREAST CANCER: DIAGNOSIS AND PROGNOSIS (Abstract): **Aim**: To assess bilateral breast cancer patients, initially diagnosed with stage II unilateral breast cancer. **Material and Methods**: 113 patients with stage 0-II breast cancer diagnosed between 1983 and 2011 were assessed. Of these, 8 patients had bilateral breast cancer: 7 patients with metachronous bilateral breast cancer and 1 patient with synchronous breast cancer. Breast ultrasound, mammography, computed tomography and magnetic resonance imaging were used to diagnose recurrence, loco regional and distant metastasis. **Results**: Age at diagnosis ranged from 37 to 59 years, with a maximum age incidence in the 4th decade (age between: 31-40 years). The average time interval between the two breast cancers was 8.125 years. The most common histological type was invasive ductal carcinoma. All eight patients with bilateral breast cancer had at least one type of recurrence/metastasis, mostly in the liver, and statistically the pleuro-pulmonary and liver metastases were the most frequent causes of death. **Conclusions**: Patients in the 4th decade diagnosed with unilateral breast cancer are at risk of developing bilateral breast cancer. In metachronous breast cancer, the time interval between the detection of the second breast cancer and death is directly proportional to the time interval between the two breast cancers. **Keywords**: BILATERAL BREAST CANCER, METASTASES, DEATH.

Primary bilateral breast cancer is rare, with a reported incidence ranging between 0.5 – 12% (1, 2). Synchronous form is less common than the metachronous one, with a ratio of 1:4 (3). The second breast cancer in the contralateral breast is more frequently diagnosed today than in the past due to the implementation of the national follow-up protocol after surgical treatment.

Bilateral breast cancer is a particular type characterized most often by a genetic component, occurs in a hormonal context and is characterized by an aggressive development (1, 4, 5).

MATERIAL AND METHODS

We retrospectively analyzed 113 patients with stage 0-II breast cancer, treated with radical or breast-conserving surgery. They were diagnosed with mammary neoplasia between January 1983 - December 2011, and deaths from breast cancer were recorded between January 2005 - December 2012. After diagnosis, patiens were referred to the

Oncology Clinics of the Iasi „Sf. Spiridon" University Hospital or Iasi Regional Cancer Institute, where they were assessed according to the national follow-up protocols. The imaging tools included standard mammography, breast ultrasound, computed tomography and magnetic resonance imaging, which allowed the detection of locoregional recurrences or distant metastases.

For statistical data analysis we used SPSS 16.00 for Windows to determine the frequency, multiple regression, enter method, regression coefficient, Pearson correlation (r), relative risk (RR) assessment, and odds ratio (OR), Chi-Square Tests, ANOVA test, test of significance (significant at $p<0.05$) and confidence interval (CI).

RESULTS

Of the 113 cases included in the study, 8 (7%) patients had bilateral breast cancer. Of these 7 (87.5%) patients had metachronous bilateral breast cancer and 1 (12.5%) synchronous breast cancer. In patients with metachronous breast cancer the interval between the two cancers was variable, as follows: 3 years in 1 patient, 5 years in 2 patients, 6 years in 2 patients, 15 years in 1 patient and 24 years in 1 patient.

In the study group the average time interval between the two breast cancers was 8.125 years (tab. I).

TABLE I

Case distribution against time interval

Breast Cancer type	No. of cases	Minimum time interval between breast neoplasms (yrs.)	Maximum time interval between breast neoplasms (yrs.)	Average time interval between breast neoplasms (yrs.)
Bilateral	8	0	24	8.1250

Age at the time of diagnosis of the first breast cancer wranged from 37 to 59 years, with a maximum frequency in the 4th decade (4 cases) (fig. 1).

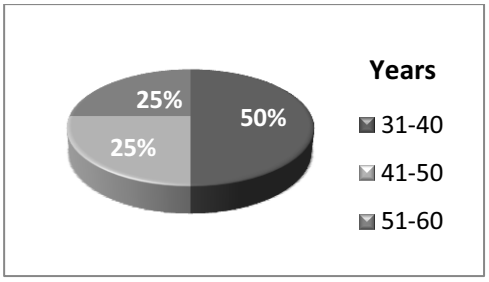

Fig. 1. Case distribution according to age at the time of diagnosis of the first breast cancer.

All patients were initially diagnosed with stage II breast cancer in one breast. Controlateral breast cancer was diagnosed as:

- stage I, in 5 patients, (breast cancer in the second breast occurred during the first six years after the first diagnosis of cancer);
- stage II, in 2 two patients (breast cancer in the second breast occurred 15 to 24 years after the first diagnosis of cancer);
- stage II, in one patient with synchrounous breast cancer.

Surgical procedures included bilateral radical mastectomy (3 patients), radical mastectomy in one breast and breast-conserving surgery in the other breast (3 patients), bilateral breast-conserving surgery (2 patients). Histopathology revealed that the most frequent type was invasive ductal carcinoma (5 cases), while intraduc-

tal carcinoma and invasive lobular carcinoma were found in one case each. One patient had invasive ductal carcinoma associated with ductal carcinoma in situ. It was noted that in a majority of cases (5 cases) the right and left breast tumors shared the same histological type, but in 3 cases the right and left breast tumors were of different histological types. Immunohistochemistry revealed that the tumors were in 5 (62.5%) patients' hormone receptor-positive and Her-2/neu protein-negative, in 2 (25%) patients hormone receptor-negative and Her-2/neu protein-negative, and in 1 (12.5%) patient hormone receptor-positive and Her-2/neu protein-positive.

All 8 patients with bilateral breast cancer had at least one type of recurrence/metastasis. Three patients had only one type of metastasis; two patients had two types of metastasis; one patient presented three types of metastasis and two patients four types of metastasis. Liver metastases were the most common (5 patients) and pleural metastases the less common (1 patient) (tab. II).

TABLE II

Case distribution by type of recurrence/metastasis

Metastasis	Local	Lymph nodes	Bone	Lung	Pleura	Liver	Skin
No. of cases (%)	3 (37.5)	2 (25)	3 (37.5)	2 (25)	1 (12.5)	5 (62.5)	2 (25)

The relative risk and odds ratio (OR) of any metastasis to determine other types of metatstasis were evaluated. When OR>1, the data are statistically significant. Although liver metastases were the most common, they were not a risk for the occurrence of other types of metastasis, being the sole type of metastasis in two patients. Only local recurrence and lymph node metatstases presented a risk for the occurrence of other types of distant metastases. Significant associations were found between local recurrences and lymph node recurrence (OR = 15.333) and lymph node recurrence and skin metastases (OR = 7.636).

The time interval between first diagnosis and death was variable: 5 years (2 patients), 6 years (2 patients), 7 years (1 patient), 9 years (1 patient) and 25 years (1 patient).

The time interval between the diagnosis of the second cancer and death was: 1 year (2 patients), 2 years (2 patients), 3 years (1 patient), 4 years (1 patient), 5 years (1 patient) and 8 years (1 patient).

In our study group, all 8 patients had bilateral breast cancer and breast cancer as a cause of cancer death. The Pearson correlation coefficient (r) was claculated to detect the association between cause of death and bilateral breast cancer or type of secondary metastases that could cause death. Pearson correlation coefficient is used to measure the strength of a linear association between two variables, where the value r = 1 means a perfect positive correlation, value r = -1 means a perfect negataive correlation, and 0 is no correlation.

In our case, it showed a significant negative correlation between causeof death and bilateral breast cancer (r = -0.246), between cause of death and lung metastasis (r = -0.562), pleural metastasis (r = -0.394) and liver metastasis (r = -0.506).

DISCUSSION

In our study the incidence of bilateral breast cancer was of 7%, similar to that reported in the literature (6), with the pre-

dominance of bilateral metachronous cancer.

A peculiarity of bilateral breast cancer in our study was the age at the first cancer diagnosis. While the literature shows an increased frequency of unilateral breast cancer in the fifth decade of life (51-60 years), in our study the patients had their first breast cancer diagnosed most commonly in the fourth decade (31-40 years) (7, 8). One particular aspect is that in most patients the breast cancer in the second breast was lower stage than in the first one (9). Thus, in all patients included in the study, the first malignancy was diagnosed in stage II and the second malignancy in stage I (5 cases). This was possible when all steps in the breast cancer imaging protocol were followed. This protocol provided a close follow-up of patients during the first 5 years after surgery: usually breast ultrasound at six months and annual mammograms. In the other two metachronous breast cancer cases, the contralateral cancer was diagnosed in stage II (more than 10 years after the first diagnosis). In these patients with stage II controlateral disease, the diagnosis wasmade during the annual breast cancer follow-up imaging. It is known that bilateral breast cancer at a young age can have a hereditary origin, and these patients may have a genetic predisposition for other type of cancer (10-14). Although our study group included patients who had another type of cancer (pancreas, stomach, colon, cervix, bladder, ovary, lymphoma, tongue), none of the patients with bilateral breast cancer had any other type of cancer.

Histology showed that invasive ductal carcinoma was the most common hystologic type in both breast tumors, and combination histologies were uncommon (one case). Although the literature shows that the immunohistochemical characteristics of bilateral breast tumors are different (15), in our study the immunohistochemical data were similar for the two breast tumors.

Bilateral breast cancer patients had various types of single- or multiple-organ recurrences/metastases, but it was statistically demonstrated that liver, lung or pleural metastases are causes of death.

In most cases with metachronous bilateral breast cancer it was found that the time interval between the second breast cancer detection and death is directly proportional to the time interval between the two breast cancer diagnoses. Thus, it was noted that when bilateral breast cancer was diagnosed after a long time (10-15 years), patient death occurs after a longer time interval (4 to 5 years) as compared to the patientsin which the time interval between the two cancers is shorter (1-5 years), when patient death occurs withinless than 4 years after the second breast cancer was diagnosed. In patients with bilateral breast cancer, metastases from the second breast cancer were the major cause of death.

CONCLUSIONS

This study revealed that patients diagnosed with unilateral breast cancer during the fourth decade of life (31-40 years) are at risk of developing a controlateral breast cancer.

In patients with bilateral breast cancer, early diagnosis depends on breast imaging according to a well-established protocol during and after the first five postoperative years.

In metachronous breast cancer the time interval between the detection of the second breast cancer and death is directly proportional to the time between the two breast cancer diagnoses.

SEVERE AMIODARONE-INDUCED BRADICARDIA CONCEALES SICK SINUS SYNDROME: CASE REPORT

SEVERE AMIODARONE-INDUCED BRADICARDIA CONCEALS SICK SINUS SYNDROME: CASE REPORT (Abstract). Sinus node dysfunction is one of the most common arrhythmias in elderly patients; it is usually associated with intermittent and variable symptoms, thus making it difficult to diagnose. We present the case of an elderly female patient with a personal history of atrial fibrillation treated for the last three years with amiodarone; she was admitted to the Geriatric Clinic for non-specific symptoms with onset two months previously for which she had already sought care in different medical services. Clinical examination showed severe bradycardia; ECG and Holter ECG on admission confirmed severe bradycardia, with a heart rate between 29 and 50 beats/min (bpm). Given her long-term treatment with amiodarone we looked for and found hyperthyroidism; the endocrine examination led to the diagnosis of mixed type Amiodarone-induced thyrotoxicosis and initiation of corticosteroid and antithyroid treatment. The evolution of cardiac arrhythmia was monitored with the help of several Holter ECGs performed after amiodarone washout and return to the euthyroid state, which revealed a tachycardia-bradycardia syndrome initially masked by the side effects of the unsupervised therapy with amiodarone, and properly treated by the implantation of a pacemaker. **Keywords**: SINUS NODE DYSFUNCTION, TACHYCARDIA-BRADYCARDIA SYNDROME, HYPERTHYROIDISM, AMIODARONE.

There are several normal age-related changes of the cardiovascular system, one of the most important affecting the conduction system with increasing fibrosis around the sinus node and loss of specialized cells and fibers. These changes, associated with a decreased response to sympathetic agonists would lead to a decreased peak heart rate and a significant decrease in heart rate variability, resulting in bradycardia, which may be further exacerbated by medication and ischemia (1). Older patients often have delayed conduction in the atrio-ventricular (AV) node, which would generate different types of AV blocks, that are usually without symptoms and could progress to complete AV block (2).

These significant changes in the anatomy and function of the conduction system of the aging heart explain the increased frequency of sick sinus syndrome, a group of arrhythmias presumably caused by a malfunction of the sinus node, including sinus arrest, sinus node exit block, sinus bradycardia and tach-

ycardia-bradycardia syndrome.

The manifestations of this disease are diverse, intermittent and often difficult to surprise on casual ECG (3), reason for which the epidemiological data are limited and the incidence of this disease in the general population remains unclear (4, 5). Syncope and/or fatigue are the cardinal symptoms in the bradycardia forms, and palpitations in the tachycardia forms, but it is not uncommon (especially in the elderly) that symptoms to be limited to dyspnea, reduced exercise capacity or mild cognitive impairment (sometimes interpreted as the onset of dementia syndrome) (6). In this context, Holter ECG monitoring remains the investigation of choice, identifying not only the accurate diagnosis but also the right moment for the implantation of pacemaker.

When confronted with fast atrial fibrillation, controlling the ventricular rate should be of the outmost importance, and the favorite antiarrhythmic drug is amiodarone (5). This trend led to a massive use of this drug in elderly patients, which was accompanied by a constantly increasing number of unwanted side effects, most frequently occurring at thyroid level. The lack of periodic and systematic control can be accompanied by serious clinical situations, such as severe bradycardia, that can be masked by nonspecific symptoms and thus easily overlooked and undertreated.

CASE PRESENTATION

We present the case of an 86 year old female patient admitted to the Geriatric Clinic for several non-specific symptoms, such as: dry and irritative cough, vertigo and generalized itching with nocturnal exacerbation. The onset of these symptoms was insidious about two months prior to this hospitalization, the patient having already sought care in different medical services. On admission she presented: facial erythema, scratching lesions on the posterior chest wall, rhythmic heart rate of 46 beats/min, and bilateral upper limb resting tremor. Her medical history revealed an episode of fast atrial fibrillation that had occurred three years earlier and was successfully treated with amiodarone, although the biochemical thyroid function tests indicated at that moment subclinical hyperthyroidism, with TSH concentration at the lower limit of normal range but with fT4 and fT3concentrations within the normal range.

Our diagnosis was severe bradycardia, most probably due to thyroid dysfunction secondary to the long-term, unsupervised treatment with amiodarone. The biochemical tests revealed very low serum levels of TSH hormone (TSH = 0.0l pmol/l), high levels of fT4 (fT4 = 30.8 µUI/ L), and normal levels of fT3. ECG on admission confirmed sinus bradycardia (Figure 1); however, the 24-hour ECG monitoring showed sinus bradycardia alternating with idioventricular rhythm; the average heart rate was 35 bpm, range 29 to 50 bpm; the absence of any cardio-cerebral symptoms allowed the postponing of pacemaker implantation.

The endocrine examination confirmed the diagnosis of mixed type amiodarone-induced thyrotoxicosis, and a treatment with corticosteroids and antithyroid drugs was initiated.

The clinical course was favorable, as the patient reported the disappearance of dry cough and prurigo 48 hours after the discontinuation of amiodarone and the heart rate slowly ascended (up to 50 bpm). A 24-hour ECG monitoring 1 month after the discontinuation of amiodarone treatment showed an average heart rate of 45 bpm, range 39 to 100 bpm, which led us to suspect an underlying, unsuspected bradycardia-tachycardia

syndrome. A third 24-hour ECG monitoring was done after 6 weeks of thyroid treatment, when thyroid function had already returned to normal; hence, we considered that this one would reflect the correct cardiac status of our patient'. The result was very much the same as the previous one, thus confirming the diagnosis of bradycardia-tachycardia syndrome, for which a pacemaker was implanted.

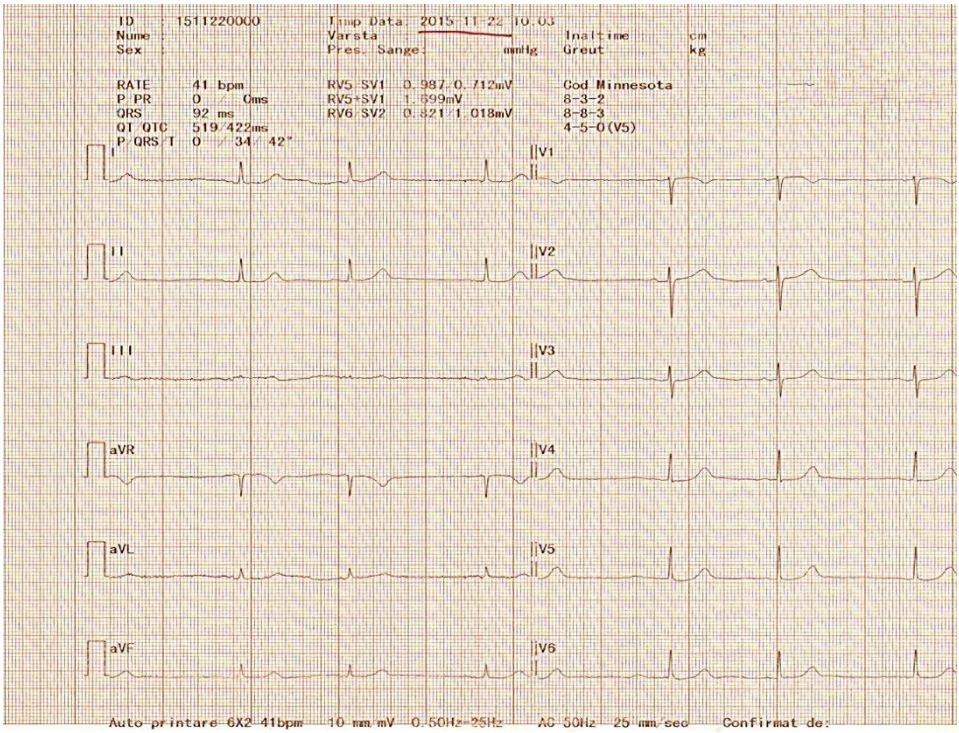

Fig. 1. ECG aspect on admission

DISCUSSION

The normal aging process of the heart includes fibrosis and loss of specialized cells and fibers of the conductive system, which would favor an increased incidence of sick node dysfunction. This condition can take many forms, including bradycardia- tachycardia syndrome. The diagnosis of this form can be difficult, as random ECG is more often normal. The bradycardia episodes are usually without any symptoms; the tachycardia episodes are associated with palpitations and the patient is wrongly diagnosed with only tachyarrhythmia and would receive an antiarrhythmic treatment, usually amiodarone. This drug should be carefully monitored, not only for the well-known side-effects, but also for the negative effect on the bradycardia episodes.

Numerous studies (7, 8, 9) show that low doses of amiodarone can be used safely in patients with fast arrhythmias and normal systolic function. However, the length of the treatment with amiodarone proved to be an independent risk factor in the prediction of adverse effects (4), mainly changes at the cardiovascular (im-

portant bradycardia), thyroid (hyper- and hypothyroidism), pulmonary and hepatic level (9, 10).

Still, the absence of cardiac symptoms (syncope, fatigue) and hyperthyroidism led to a delay in the diagnosis. This case also presented some of the less known side effects of amiodarone, that include nervous system disorders (paresthesia, pain and muscle weakness, tremor, walking and moving disorders, headache, vertigo), gastrointestinal disorders (nausea, taste alteration, constipation, lack of appetite) or skin disorders (itching, petechiae) (8) that can be easily interpreted as a concomitant chronic or aging-related disease.

CONCLUSIONS

Our case emphasizes the need for sustained monitoring of treatment with amiodarone; the multiple side effects (cardiovascular and thyroid) associated with the progression to a higher-degree AV block led to severe bradycardia, fortunately without cerebral and cardiac consequences.

The therapeutic decision, especially in tachycardia-bradycardia syndrome should be carefully considered; the patients that require antiarrhythmic therapy should be rigorously monitored, mainly those treated with amiodarone, and the 24-hour ECG monitoring should be the safest way for identifying the excessive secondary "bradicardization".

POSTOPERATIVE ARTERIAL RELAXATION AND INTRAOPERATIVE VENOUS DILATION AS INTERCONNECTED PROGNOSTIC FACTORS FOR THE MATURATION OF ARTERIOVENOUS FISTULAS (Abstract) **Aim**: To investigate if immediate arterial distention can be used as a predictive factor for the development of a good fistula. **Material and methods**: Over a 5-months period (January- May 2015) all the patients who underwent an arteriovenous fistula between the radial artery and the cephalic vein of the forearm at the Second Surgical Clinic of the Iasi Regional Cancer Institute and were willing to participate were enrolled in the study. The diameters of the vessels were measured 1 hour and 8 weeks after surgery. **Results:** We found statistically significant differences for all measured diameter variations between the calcified artery and normal artery groups ($p<0.001$ for the arterial distention at 1 hour and 8 weeks after surgery and $p=0.002$ for the venous distention 8 weeks after surgery). A linear regression also showed that the degree of arterial distention immediately after surgery and the venous distention 8 weeks after surgery were statistically correlated. **Conclusions**: Arterial distention immediately after surgery and therefore the lack of it due to the presence of arterial calcifications can be used to predict whether or not a good fistula can be achieved at a 1% statistical significance level. **Keywords**: HAEMODIALYSIS ACCESS, ARTERIOVENOUS FISTULA, PREDICTIVE FACTORS OF FISTULA MATURATION, ARTERIAL RELAXATION

INTRODUCTION

The purpose of any arteriovenous anastomosis for hemodialysis access is the development of a functional fistula which is as close to the ideal as possible. As a definition, an adequate fistula is located at a depth of 6 mm from the skin surface, has a minimum diameter of 6 mm and can accommodate a blood flow higher than 600 ml/minute (1). A major limiting factor in achieving such a fistula is the caliber of the vessels to be anastomosed, not necessarily from a technical point of view but because there are certain limits below which the development of an adequate fistula is impossible. Parmar et al. (2) showed that 45.5% of the arteriovenous fistulas created by using an artery with a diameter < 1.5 mm had failed to mature within 12 weeks, compared to an artery > 1.5 mm where

maturation was reached in all cases. They also found statistically significant difference in blood flow rates if the artery before surgery was <1.5 mm (347 ml/minute) or >1.5 mm (521 ml/min). Regarding the vein diameter, Mendes et al. (3) reported that 16% of fistulas were adequate with a vein diameter of 2 mm or less, compared to 76% of those larger than 2 mm. Fila et al. (4) showed that when the initial vein diameter was less than 2 mm only 60.2 % of the fistulas reached maturation. In this group of functional fistulas the intraoperative vein dilation leads to an average 75% increase while in the group of non-functional fistulas the average intraoperative distention of the vein was only 48 %, showing that vein elasticity is also of great importance (4).

MATERIAL AND METHODS

The aim of the study was to evaluate if arterial relaxation immediately after surgery, arterial relaxation within the first 8 postoperative weeks and intraoperative vein dilation correlate with vein distention 8 weeks after surgery, as a measure of fistula maturation.

Between January and May 2015, a number of 19 patients underwent an arteriovenous fistula between the radial artery and the cephalic vein of the forearm at the Second Surgical Clinic of the Iasi Regional Cancer Institute.

Of the 19 study patients 12 (63.2 %) were women and 7 (36.8 %) men. The mean age of the patients was 55 ± 13.63 years, range 24-80 years. Eight patients (42.11%) had diabetes. Twelve patients (63.2%) were included in the group of patients with a normal, elastic artery and 7 (36.8%) in the group with calcified artery.

Inclusion criteria: patients with end-stage chronic kidney disease in which an arteriovenous fistula between the radial artery and the cephalic vein of the forearm was created. Exclusion criteria: patients with fistulas other than one between the radial artery and the cephalic vein of forearm; patients unwilling to participate in the study.

The patients enrolled in the study were assigned to 2 study groups according to the macroscopic appearance of the arterial wall during surgery: the first group included diabetic patients with calcified arteries that were practically non-distensible, transformed into a rigid tube; the second group included patients with a macroscopically normal artery.

Before surgery the blood pressure was measured in both arms and vein diameter was measured using ultrasound (5) at a point located 4 cm above the anastomosis so as not to compromise the wound dressing when measuring the vein after surgery. The initial measurement of vein diameter was performed without a tourniquet in order to assess its ability to distend. The diameter of the artery was also measured at 4 cm above the anastomosis. The measurements were taken preoperatively, one hour postoperatively, and 8 weeks after surgery (during the first dialysis appointment). Each measurement was performed 3 times and the average of these measurements was recorded.

All of the patients underwent an arteriovenous anastomosis in a side-to-end fashion between the radial artery and the cephalic vein of the forearm. The diameter of the venous side of the anastomosis was increased by up to 50% by using a longitudinal incision in the venous wall. That was the reason why in all cases the anastomosis diameter was 50% larger than the vein diameter before surgery. The vein was

dilated by injecting an isotonic saline solution while digitally compressing the vein. After surgery, all patients were advised to perform flexion exercises for 8 weeks.

The statistical analysis of the data was performed using IBM *SPSS* version 17.0 for Windows. The statistical tests performed were the student t-test in order to check for statistically significant differences between groups and linear regression in order to assess whether or not immediate arterial and venous dilation can be used to predict the fistula outcome. For this study, a 5% significance level was considered satisfactory.

RESULTS

We compared the percentage of arterial and venous distention immediately after surgery and at 8 weeks after surgery and the percentage of the vein dilation at 8 weeks after surgery, between the patients with a macroscopically calcified radial artery and those with a macroscopically normal artery, as assessed during surgery.

The mean arterial distention 1 hour after surgery in calcified artery patients was 2.28 ± 3.23% compared with 37.52 ± 12.75% in normal artery patients. When assessed at 8 weeks after the procedure, the mean arterial distention in the calcified artery group was 9.36 ± 9.36 %, while in the normal artery group it was 97.25 ± 47.18 %.

As to vein distention we found that intraoperative distention in the calcified artery group was 202.24 ± 105.69 %, while in the normal artery patients it was 117.99 ± 112.19%. The venous distention 8 weeks after surgery in the calcified artery group was 31.85 ± 5.44 % and 95 ± 44.11% in the normal artery group.

We then analyzed the differences between these diameter variations from a statistical point of view using an independent samples t-student test. We found that the difference between the calcified artery and normal artery groups was statistically significant for all diameter variations with $p<0.001$ for arterial distention at 1 hour and 8 weeks after surgery, and $p=0.002$ for venous distention 8 weeks after surgery.

As a final step in our analysis we performed a linear regression analysis of arterial distention 1 hour after surgery and venous dilation 8 weeks after surgery and we came to the conclusion that arterial distention immediately after surgery and therefore the presence of arterial calcifications can be used to predict whether or not a good fistula can be achieve at a 1% statistical significance level ($p<0.001$, r-square 0.72). However, when comparing intraoperative venous distention and venous distention 8 weeks postoperatively we found that intraoperative venous dilation is a less effective predictor of fistula outcome ($p=0.021$, r-square 0.24).

DISCUSSION

Determining whether a fistula is adequately matured or not is very important and hemodialysis nurses can do that. In more and more studies their experience has been considered the best tool for fistula assessment, before even measuring the flow through the fistula. The clinical criteria followed are: a superficial vein, with a diameter adequate for the puncture, with a uniform thrill and a length of minimum 10 cm available for puncture (6).

Once the fistula is opened during the procedure, the wall of the vein withstands a higher pressure than the venous pressure which causes structural alterations of the wall. Depending on the capacity of the wall to distend the vein lumen it thickens by

hypertrophy of smooth muscle cells. Thus, the venous wall becomes resistant to repeated punctures and extrinsic compression (7).

When the vascular clamp is removed from the artery after the anastomosis is completed there is a rapid redistribution of the blood flow in the region depending on pressure gradients and flow resistance. The overall resistance downstream to the artery anastomosed to the vein decreases. The flow thus increases through a constant section of the artery and the speed of the flow and the shearing stress are also increased leading to a progressive dilation of the artery (8).

The mechanism through which the arterial wall becomes increasingly rigid and thus reduces the vascular compliance required to maintain adequate flows through the fistula are not entirely known. They may include fluid overload, arterial calcification, inflammation, activation of the sympathetic and rennin–angiotensin system, increased lipid oxidation, nitric oxide anomalies (9). The increased arterial wall rigidity has direct implications on fistula outcome because given the inadequate blood flow through the fistula hemodialysis is not effective. An example is the diabetic patient in which the accelerated atherosclerosis transforms the artery into a rigid tube unable to relax and increase the blood flow (10).

A key role in arterial wall relaxation is played by the nitric oxide. Its synthesis is increased by the alterations in local blood flow, as shown by many studies (10, 11, 12). It is also responsible for the activation of metalloproteinases in the extracellular matrix of the cells within the vascular wall. These lead to the destruction and reorganization of the cellular matrix that could explain the changes occurring in the vascular wall (13).

The parameters analyzed in our study were the intraoperative venous dilation, the postoperative arterial dilation measured 1 hour after the procedure and the arterial and venous dilations 8 weeks postoperatively. The choice of these parameters was based on physiological reasons, as we believed they all play a role in achieving an adequate venous distention: the intraoperative venous dilation is a measure of vein elasticity; the venous distention between the measurement performed 1 hour after procedure and 8 weeks after surgery is due to hemodynamic factors and vein elasticity; the arterial distention between the preoperative measurement and the measurement 1 hour after the procedure evaluates the immediate capacity of the artery to relax after the decrease in the resistance distal to the fistula; arterial distention 8 weeks after the procedure shows how well the artery has accommodated to the new hemodynamic conditions in order to increase the flow through the fistula.

In our study, in the patients with calcified arteries the differences between the diameter of the artery before the procedure and 1 hour after the procedure were, as expected, quite small, due to the fact that the calcified artery is basically a rigid tube. However, in the group of patients with macroscopically normal arteries, there was a significant increase in the diameter of the artery after surgery, but the increase was extremely variable, depending on each patient's hemodynamic condition, as shown by the large standard deviation.

The venous dilation was considered of great importance in our study because the vein size at 8 weeks after the procedure is very important in determining whether the fistula had adequately matured or not. It is for this reason that we tried to assess

whether arterial distention immediately after surgery and arterial distention 8 weeks after surgery can be used to predict adequate fistula maturation, assessed in our study by the distention of fistula between the measurement performed 1 hour after surgery and 8 weeks after surgery. We found that both the immediate and late arterial distention are a good predictor of late venous distention, and even better than the intraoperative venous distention. This shows that an artery capable to relax in order to increase the flow through the fistula is essential for an adequate maturation of the fistula.

An adequate increase in the diameter of the vein or artery alone does not independently result in a patent fistula.

If the vein is elastic and dilates well during the procedure it does not mean that it will produce a good fistula unless the artery is able to relax and increase the blood flow.

At the same time a healthy, non-calcified artery can in time progressively dilate a vein that appeared to be unable to dilate during the procedure. Arterial relaxation happens immediately in normal arteries and our study shows it can be used as a prognostic tool of adequate fistula maturation.

CONCLUSIONS

We have shown that good immediate arterial distention also means an adequate, matured fistula 8 weeks after the procedure. At the same time the immediate venous distention is also a prognostic factor of an adequate fistula and we believe that together the elasticity and compliance of the arterial and venous walls are inextricably linked in determining the outcome of a fistula.

SELENIUM SUPPLEMENTATION VIA BRAZIL NUT IMPROVES THYROID HORMONE LEVELS IN HEMODIALYSIS PATIENTS: A PILOT STUDY

Hemodialysis (HD) for pacients known with renal failure is associated with low levels of total and free T3 (triiodothyronine). This fact that can be explained partialy by a selenium (Se) deficit that is also a common feature for HD. Selenium is an essential micronutrient important for the thyroid hormone metabolism. This study aimed to investigate the effect of selenium supplementation via Brazil nut (rich in Se) on thyroid hormone levels on HD patients. Fourty patients with HD received for 3 months one nut daily that contained in average 58.1 mg Se. All patients presented at baseline a Se deficit, low T3. After the intervention, Se, FT4 (free thyroxine) and GPx (glutathione peroxidase) activity plasma levels arised significantly increased ($p < 0.05$), while the TSH levels were reduced but not significantly. In conclusion, by increasing Se levels an improvement in thyroid hormone levels in HD patients is obtained (Stockler-Pinto M B, Carrero J J, Carvalho L *et al* Effect of selenium supplementation via Brazil nut (Bertholletia excelsa, HBK) on thyroid hormones levels in hemodialysis patients: a pilot study. *Nutr Hosp*. 2015;32(4):1808-1812).

INCIDENCE OF REASONS FOR REVISION HIP SURGERY: PRELIMINARY STUDY (Abstract). **Aim**: To analyze the main causes and short/mid-term clinical outcomes of revision total hip arthroplasty**. Material and Methods**: All patients treated over a period of 36 consecutive months at the Orthopedic Clinic of the Iasi Rehabilitation Hospital were analyzed. The causes for total hip arthroplasty (THA) failure were grouped into one of the six categories: aseptic loosening, infection, dislocation, component wear, periprosthetic fracture, and pain. **Results:** The rate of risk for THA failure is differently influenced by factors such as age, weight index, associated comorbidities, gender, and physical activity level. Most revisions (72.4%) were for aseptic loosening. Age group distribution showed that most patients who required revision, regardless of age group, were women. **Conclusions:** Although the risk of infection is higher in the first six weeks after surgery, early infections rarely require partial or total replacement of the prosthesis. Infections that require prosthesis revision are late and deep, but the incidence of such complications is low. Loosening is the most common cause of THA failure. **Keywords:** ARTHROPLASTY, CAUSES OF FAILURE, LOOSENING, INFECTION.

Most studies on the success rate of primary hip arthroplasty show that this surgical procedure provides early resumption of joint mobility and normal functioning of the articular and periarticular structures that control the movement of the coxofemoral joint. Even though primary THA ensures restoration of hip biomechanics, complications affecting the quality of reconstruction, which lead to THA failure and require partial or total revision may occur with time (1).

Several authors have reported success rates of about 90% for primary THA 10 years after surgery, increasing to 95% in patients over 75 years (2). As to the incidence of causes for revision articular reconstruction the reported values relatively differ from one study to another, depending on the geographical area and prevalence of risk factors (3, 4, 5).

A study aimed at assessing the indications for revision and understanding the mechanisms and timing of primary THA failure revealed that high activity level is an important risk factor especially in

younger patients (6).

The aim of this study was to analyze the main causes and short/mid-tem clinical outcomes of revision THA in the Orthopedic Clinic of the Iasi Rehabilitation Hospital.

The overall objective of this study was to identify and rank the causes of primary hip arthroplasty failure in order to optimize joint reconstruction.

The study had the following subjacent goals: to identify and analyze the reasons for primary THA failure, to evaluate the mid-term clinical outcomes of revision THA,and to compare our results with those of similar studies.

MATERIAL AND METHODS

The study protocol included:

• collection, centralization and grouping of clinical data and information on the prosthetic materials used in revision hip arthroplasty;

• statistical processing of clinical data in order to determine the level of significance of the findings regarding the reasons for revision hip arthroplasty;

• creating a database on revision hip arthroplastiesin view of evaluating and correct selection ofthe prosthesis and arthroplasty technique for a reduction in the failure rate of endoprostheses.

The retrospective observational study was conducted on a total of 29 cases operated at the Orthopedic Clinic of the Iasi Rehabilitation Hospital in the interval 2011-2014.

For this study we used information from the medical records and records of surgical procedures of a consecutive series of 29 revisions performed in 24 patients. The mean postoperative follow-up was 12 months (range 6 to 24 months).

Detailed clinical and demographic data were extracted for each patient: age at first intention hip arthroplasty, sex, diagnosis, prosthesis survival time, and the exact cause/causes for primary hip arthroplasty failure.

The primary data sources included perioperative charts, operative notes, discharge summaries and relevant radiographs.

The primary diagnosis was grouped into the following categories: osteoarthritis, inflammatory arthritis (including rheumatoid arthritis and ankylosing spondylitis), osteonecrosis, hip dysplasia, post-traumatic arthritis and a miscellaneous group of other causes.

Harris hip scores were used to quantify clinical outcomes. Patients were scheduled for clinical and radiological follow-up at 3, 6 and 12 months and annually thereafter. The mean postoperative follow-up was 1 year.

In each case, the reason for failure was classified into one of the following six categories: aseptic loosening, infection, instability, component failure, periprosthetic fracture, or pain. In 3 cases in which there were multiple reasons for failure these were equally considered in systematizing the data.

RESULTS AND DISCUSSION

To analyze the incidence of reasons for revision the information on the 29 revision total hip arthroplasties included in the study were systematized. The causes of failure were:

- component loosening (septic and aseptic) of total hip prosthesis (21 cases; 72.4 %),
- periprosthetic fractures (5 cases; 17.2% - 3 cases Vancouver type B2 and 2 cases Vancouver type B3)
- luxation of hip prosthesis (2 cases; 6.9 %),
- deterioration of the femoral stem (1

case; 3.4 %).

Of the 24 patients, two thirds were women and only one third were men.

The mean age of the study patients at the time of revision was 64 years (range 46-84 years).

Age group distribution of the study patients showed that regardless of age group most of the patients who required revision were women (fig. 1).

The analyzed data showed that in the study group aseptic loosening, with an incidence of 72.4%, is the most frequent reason for revision (fig. 2).

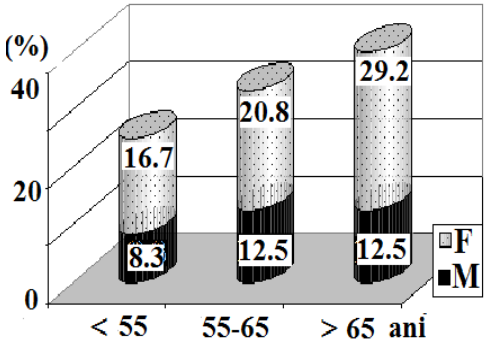

Fig. 1. Age group distribution of the study group

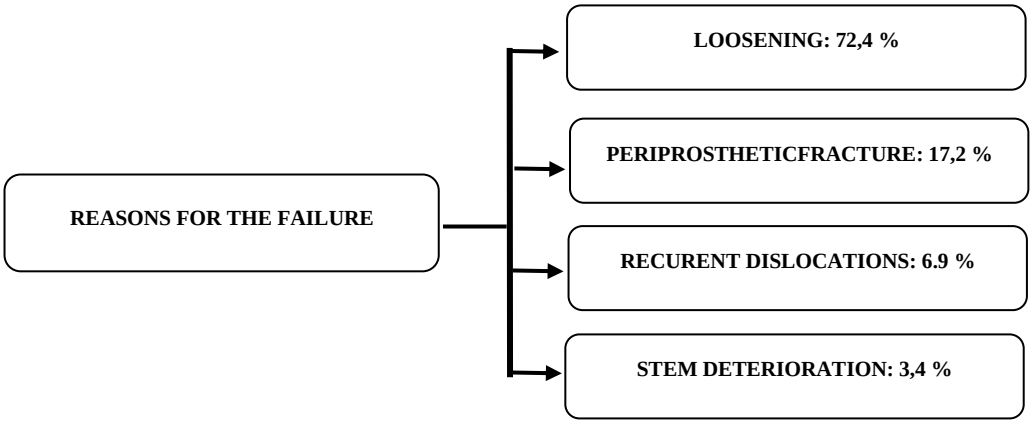

Fig. 2. Incidence of reasons for revision in the study group

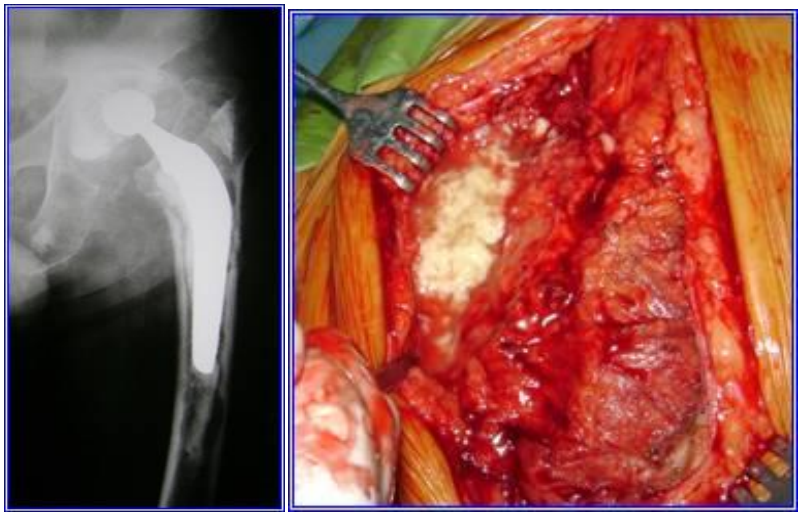
Analyzing the data on the 2.107 first intention THAs performed in France from January 1, 2010 to December 31, 2011, Delaunay et al. (7) showed that the reasons for revision in order of priority were: mechanical loosening (42%), periprosthetic fracture (12%), infection (11%) wear/ osteolysis (11%), dislocation (10%), surgical technique error (6%), implant deterioration (3%). The revision procedure used in half of the cases (49%) was all-component revision. The study also revealed that although dislocation was not the main cause for primary THA failure, it remains the most common early complication after revision.Katz et al. (8) conducted a retrospective cohort study of patients who had elective total hip replacement for osteoarthritis in the United States between July 1, 1995, and June 30,1996,and a 12 year follow-up period. The data showed that the risk of revision THA for the surviving patients was approximately 2% per year for the first eighteen months and then 1% per year for the remainder of the follow-up period. The absolute risk of death over the follow-up period (12 years) exceeded the risk of revision THA by 10 times (59% vs. 5.7%) in patients

older than 75 years at the time of primary THA and by 3 times (29% vs. 9.4%) in patients aged 65 to 75 years at the time of primary surgery.

In multivariate Cox proportional hazard models, the relative risk of revision was higher in men than in women. In patients aged 65 to 75 years at the time of primary THA the relative risk of revision was 1.23 (1.15, 1.31, CI = 95%) and in those over 75 years of 1.47; (1.37, 1.58) CI = 95%.

Corbett et al. (9) identified in the literature a number of population-based studies assessing the 10-year revision risk (2000-2010). The analysis of data in the national THA registries from England and three Scandinavian countries (Sweden, Finland and Norway) suggests revision risks stratified by age and fixation technique of 5% to 20% at ten years after surgery. Kaplan-Meier estimates showed that cemented implants had ten-year revision-free implant survival rates of 88% to 95% and the uncemented implants of 80% to 85%. In patients under 60 years at the time of primary surgery revision-free implant survival rates ranged from 72% to 86% and in those older than 60 years the rates ranged from 90% to 96% (9).

Mobilization of the hip prosthesis may be due to periprosthetic loosening or polyethylene wear. These phenomena, often due to uneven distribution of forces involved in hip biomechanics, cause unnatural tribological couples generating very small particles. The composition of such particles, polyethylene, acrylic cement, ceramic or metal, depends on the endoprosthesis type (10). Patient's immune system will recognize such particles as a foreign body and will generate an immune response. A strong response to wear particles may result in biological bone resorption (osteolysis) and loosening (fig. 3).



(Collection of Iasi Rehabilitation Hospital – Orthopedic Clinic)

Fig. 3. Hip X-ray image of a 68-year-old patient operated upon 9 years earlier with an osteolytic area and acetabular and femoral loosening on hip x-ray; intraoperative view, seropurulent discharge at the proximal femur

Loosening is more likely as the physical demand that will be placed on the joint after surgery is higher. This accounts for the higher incidence of this cause of HTA failure in younger and more physically active patients (fig. 4).

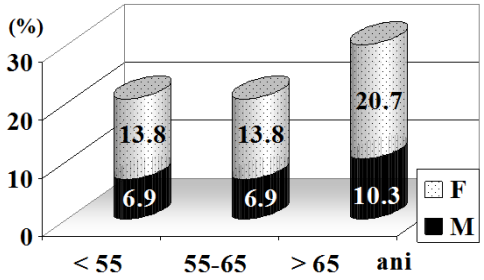


Fig. 4. Incidence of loosening by age group and sex

Although multiple dislocations are rare, some elderly, debilitated patients, or those with other locomotor deficiencies are prone to this complication. The risk of dislocation is higher during the first months after surgery. In case of repetitive dislocations revision surgery is necessary (Fig. 5).

A study by the Mayo Clinic (11) on 10,500 THAs reported a 3 times greater risk of dislocation with the posterolateral approach (4.3%) compared to the anterior (1.8%) and anterolateral (1.7%) approaches.

Dudda et al. (12) found a 6 times greater risk of dislocation with the posterior approach compared with the anterolateral approach or lateral approach with trochanteric osteotomy.

Fig. 5. Upper left hip prosthesis dislocation *(Collection of Iasi Rehabilitation Hospital – Orthopedic Clinic)*

CONCLUSIONS

In our study, data analysis shows that loosening is the most common reason for revision exceeding by one order of magnitude any of the other immediate or late complications.

The rate of the risk of revision THA differ with respect to the mechanism of failure and is influenced differently by such factors as age, weight index, associated co morbidities, gender, physical activity level.

Revision surgery for recurrent dislocations requires repositioning or even replacing of the prosthetic components.

Infection after THA can occur at any time after surgery. Although the risk of infection is higher in the first six weeks after surgery, immediate infections rarely require partial or total replacement of the prosthesis. Infections that require prosthesis revision are late and deep, but the incidence of such complications is low.

ANTIMICROBIAL ROLE OF FILAGGRIN-2 PROTEIN

Filaggrin-2 (FLG2) is a water-insoluble 248 kDa S100 fused-type protein found in the upper epidermis and eccrine sweat glands. A study by Hansmann *et al.* tested the antimicrobial activity of filaggrin-2 against *Pseudomonas aeruginosa* and other Pseudomonads and found that recombinant FLG2 C-terminal protein fragments have potent antimicrobial activity against *P. aeruginosa* and after cultivation of *P. aeruginosa* on stratum corneum, antimicrobially active FLG2 fragments are released from insoluble material by the bacteria themselves. These FLG2 C-terminal fragments have an alternative mode of action different from most other antimicrobial peptides, as they do not induce pore formation, but membrane blebbing. According to Hansmann et al., FLG2 fragments interfere with bacterial replication, inhibit their growth on skin surfaces and contribute to the skin's antimicrobial defense, explaining why *Pseudomonas* infections of healthy skin are very rare. Also, the absence of filaggrin 2 at certain body surfaces and in the case of burned skin seems to be responsible for the higher susceptibility to these infections. The study concluded that FLG2 C-terminal fragments could represent new *Pseudomonas*-targeting antimicrobials (Hansmann B, Schröder JM, Gerstel U. Skin-Derived C-Terminal Filaggrin-2 Fragments Are Pseudomonas aeruginosa-Directed Antimicrobials Targeting Bacterial Replication. PLoS Pathog. 2015;11(9):e1005159. doi: 10.1371/journal.ppat.1005159).

THE IMPORTANCE OF CLINICAL AND INSTRUMENTAL DIAGNOSTIC IN THE MAMMARY GLAND CANCER (abstract): Breast cancer is the most common oncology disease in women and is one of the major public health issues. Worldwide, is the second leading cause of cancer death in women and cancer research is a priority in all the laboratories of the world, in terms of uncovering the appearance causes of the malignant process, understanding the mechanisms of development, but most of all, the discovery of early diagnostic methods and effective treatment. Ignorance, fear of diagnosis, lack of health education and of efficient programmes for prevention and screening could cause diagnosis of the disease to be detected in the majority of cases in advanced stages, when treatment remains only palliative and very costly, in this cases the patient's suffering being immense. In this way, regarding the clinical diagnosis in stage I mammary gland cancer, in the 496 stage I MGC patients, during the primary clinical investigation the diagnosis of stage I MGC was established only in 165 (33.3%) patients, and in 232 (46,8%) patients the diagnosis of suspicion MGC was obtained. Also, in terms of instrumental diagnosis, such as mammography, ultrasonography in mammary gland cancer stage I, it seems that in accordance with literature data the pathological process features assessment in the mammary gland is problematic especially in young age. Thus, it seems that MGC represents a polymorphic and pathogenic disease and it cannot be admitted that all subgroups of patients will obtain identical results from one tactic of treatment determined for all the patients with MGC. In this way, the concept of MGC both clinical and patho morphological, combines different cell clones depending on its microstructure and biology. As a result, the evolution of the disease, the prognosis and the effectiveness of the treatment may vary in different patients at the same stage, depending on the degree of malignancy of the tumor, its histopathological structure, the degree of expression of molecular markers identification and also immune resistance. **Keywords:** MAMMARY GLAND CANCER, BIOLOGICAL RELEVANCE, DIAGNOSTIC.

Breast cancer is the most common oncology disease in women and is one of the major public health issues. Worldwide, is the second leading cause of cancer death in women and cancer research is a priority in all the laboratories of the world, in terms of

uncovering the appearance causes of the malignant process, understanding the mechanisms of development, but most of all, the discovery of early diagnostic methods and effective treatment (Devi et al., 2000).

Ignorance, fear of diagnosis, lack of health education and of efficient programmes for prevention and screening could cause diagnosis of the disease to be detected in the majority of cases in advanced stages, when treatment remains only palliative and very costly, in this cases the patient's suffering being immense.

This is also very important since mammary gland cancer (MGC) is one of the most common malignant tumors in women. In this way, in 2008 its morbidity was extremely increased especially in the Eastern Europe, where it was 38% in Ukraine, in Moldova - 25,4 %, while in Russia it was 38,2% and in Romania it was around 39.8%. Also, in the economically developed countries it represents up to 15-20 % of all cases of death by cancer in women and 3-5 % of all deaths (Fitsgibbons et al., 2001).

It is generally believed that conservative surgical treatment for the mammary gland represents a surgical operation by which the tumor with the adjacent mammary glandular tissue is removed with the evidation of the axillary and subclavicular lymph nodes, but keeping the organ (the so-called organ saving surgery).

The contemporary stage in surgery is characterized by an increasing share of organ saving operations in MGC stage I. Also, the most published sources indicate that the best results after organ saving operations were obtained in stage I of MGC (Hamilton et al., 2000; Vitucci et al., 2000). Moreover, the frequency of organ saving operations during treatment of MGC depends, in the first place, on the proportion of registered patients with the early stages of the MGC.

Moreover, due to various causes (e.g. suspicious multicentre tumor growth, affecting central quadrant, and suspicious metastatic involvement of axillary lymph nodes) the share of mastectomies in the surgical treatment of MGC remains high. Also, taking into account the fact that the average age of patients with MGC has decreased in the recent years, the organ saving surgical interventions and keeping of the mammary gland have become more and more significant, especially in reducing the mental trauma of the patients with MGC (Goldhirsch et al., 2007).

So far, there is no firm decision regarding the selection of the optimal order in the stages of treatment. In this way, these could represent very important aspects which could contribute to an increase in the survival of MGC patients.

Thus, an important aspect of the present study referred to the selection for the prognostic decisive factors in the biological development variance of the tumoral process for the elaboration of optimal treatment schemes in stage I MGC.

MATERIAL AND METHODS

The material of this study includes clinical and laboratory data analysis, the informational value of various investigation and treatment methods on 680 patients, selected between 1996 and 2004.

The patients included in the study were divided into 3 groups: the retrospective group, the prospective group and the control group.

In this way, the **retrospective group** included 496 stages I MGC patients, diagnosed and treated during 1996-2004. The

retrospective group was divided into 2 groups according to the type of clinical development of tumoral process after treatment: the 1st group including 419 patients without progress for 5 years after the treatment, and the 2nd group including 77 patients with the progressing tumoral process after treatment.

On the other side, the **prospective group** included 66 stages I MGC patients, diagnosed and treated between 2007-2008. For the patients in the prospective group there were assessed the molecular expressions of the HER2/neu molecular markers, CEA tumoral markers, CA-15.3, hormonal receptors RE and RP, hormonal homeostasis and immunological indices.

Finally, **the control group** comprised of 118 patients, from which 56 patients with Ha, Ilb, or lila stage MGC, and 62 patients with benign diseases.

In the control group the immunological and homeostasis hormonal parameters were studied for comparison with the stage I MGC.

A special inquiry was developed for this study, which included 150 parameters regarding special body or tumor features, the informational of various methods of investigation and the results of different treatment variants applied.

Data analysis

The decisive prognostic factors determination was performed by discriminate analysis. By applying discriminate analysis - within the groups of the retrospective lot the decisive prognostic factors of the clinical evolution variance were determined in the stage I MGC patients.

RESULTS

In this way, regarding **the clinical diagnosis in stage I mammary gland cancer,** in the 496 stage I MGC patients, during the primary clinical investigation the diagnosis of stage I MGC was established only in 165 (33.3%) patients, and in 232 (46,8%) patients the diagnosis of suspicion MGC was obtained. In other cases, the pathological process in the mammary gland was found as benign disease - fibro-adenoma (6.0%), fibrocystic disease nodules in 8.7% or other variations - in 5.2% cases (tab. I).

TABLE I

The variance of the clinical diagnosis variants in stage I MGC as depending by age

No	Clinical diagnosis	The age of patients						Total	
		< 35 years old		35 - 49 years old		> 50 years old			
		31 patients		224 patients		241 patients		496 patients	
		No. abs.	%	No. abs.	%	No. abs.	%	No. abs	%
1	Cancer	6	19.4	61	27.2	98	40.7	165	33,3
2	Cancer susp.	10	32.3	107	47.8	115	47.7	232	46.8
3	MFC	3	9.7	33	14.7	7	2,9	43	8.7
4	FA	11	35.5	14	6.3	5	2.1	30	6.0
5	Other*	1	3.2	9	4.0	12	5.0	26	5.2

Also, in terms of instrumental diagnosis – mammography, ultrasonography in mammary gland cancer stage I, it seems that in accordance with literature data the patholog-

ical process features assessment in the mammary gland is problematic in young age, especially due to the proliferating changes in the mammary glandular tissue adjacent to the tumor which contribute to the lessening of the clinical picture, including the palpable one, which decreases the possibility of accurate clinical assessment regarding the character of the pathological process in the mammary gland.

Additionally, by analyzing the frequency of correct clinical diagnosis of stage I MGC during the clinical primary investigation by age, we found the following: for the patients up to 35 years, the correct diagnosis of MGC was established only in 19.4% cases, while for the patients aged between 35-49 years old in 27.2% cases.

Moreover, in the patients aged over 50 years old, when the adjacent background is presented by adipose metaplasia of mammary glandular tissue, which allows a correct assessment of the size, density, surface and character of the tumor, the frequency of accurate diagnosis assessment was the highest-40,7% cases. Therefore, during menopause, for the glandular tissue metaplasia, based only on clinical data the correct diagnosis of stage I MGC was established in less than half of cases.

Also, analysis for the frequency of the correct diagnosis setting at the first clinical investigation in relation to the tumor dimensions found that in tumors with a diameter < 0.5 cm the clinical diagnosis was correct only in 11.6% cases, while from 0.6 – l.0 cm the frequency of correct MGC diagnosis setting essentially increased up to 41.6% cases and in tumors l.l-2.0 cm in 38.4% cases (tab. II).

TABLE II

Clinical diagnosis variants in stage I MGC, as depending of the tumor dimensions

No	Clinical diagnosis	The dimensions of the tumors						Total	
		< 0.5 cm		0.6-l.0 cm		l.l-2.0 cm			
		43 patients		166 patients		219 patients		428 patients	
		No. abs.	%	No abs.	%	No abs.	%	No abs	%
1	Cancer	5	11.6	69	41.6	84	38.4	158	36.9
2	Cancer suspicion	17	39.5	72	43.4	112	51.1	201	47.0
3	MFC	10	23.3	14	8.4	10	4.6	34	7.9
4	FA	6	14.0	4	2.4	6	2.7	16	3.7
5	Other*	5	11.6	7	4.2	7	3.2	19	4.5

In addition, the instrumental investigation, mammography in particular, is considered a diagnostic method with higher possibilities than the clinical ones and it is recommended as a method for the preclinical detection of patients with suspected mammary glands cancer, inclusively within the framework of prophylactic investigations for women after age 35, when the adipose metaplasia of breast glandular tissue occurs.

Also, within the complex investigations mammography was performed in 287 (57.9%) patients out of whom the correct diagnosis of mammary gland cancer was established for 70 cases.

In this way, by analyzing the frequency of the mammography correct diagnosis of

stage I mammary gland cancer based on patients age, the correct diagnosis of stage I mammary gland cancer for the patients under 35 years of age was 50%; for the age group between 35-44 years was 66.9% cases, and for patients older than the age of 50 was of 74.1% cases.

Additionally, through the analysis of the mammographic findings, depending on the tumor size, the following results were obtained: in tumors with size TIa: < 0.5 cm the correct mammographic conclusion of cancer of the mammary gland was established 4 times more frequently compared to clinical examination corresponding to 52.2% respectively 11.6% cases.

Also, for tumor size T Ib: 0.6-1.0 cm the mammographic correct diagnosis was established in 70.7% cases, while the correct diagnosis registered a even higher frequency for tumor sizes Tic: 1.1 - 2.0 cm, which means 76.2% of the cases (tab. IV).

TABLE III

Mammographic findings in stage I MGC, as determined by the patients age

No	Mammographic conclusions	The age of patients						Total	
		< 35 years old		35 - 49 years old		> 50 years old			
		8 investigated patients		136 investigated patients		143 investigated patients		287 investigated patients	
		No. abs.	%	No abs.	%	No abs.	%	No abs	%
1	Cancer	4	50,0	91	66,9	106	74,1	201	70,0
2	FAM	1	12,5	36	26,5	29	20,3	66	23,0
3	FA	3	37,5	9	6,6	8	5,6	20	7,0

$\mathbf{X^2} = 2.96$ $\mathbf{p} > 0.05$

TABLE IV

Mammographic findings in stage I MGC patients, after to the tumor diameter.

Mammographic conclusions	The dimensions of the tumor						Total	
	< 0.5 cm.		0.6-l.0 cm.		l.l-2.0 cm.			
	No. abs.	%	No. abs.	%	No. abs.	%	No. abs.	%
Cancer	12	52,2	70	70,7	96	76,2	178	71,8
MFC	9	39,1	19	19,2	24	19,0	52	21,0
FA	0	0	9	9,1	5	4,0	14	5,6
Solitary chistum	2	8,7	1	1,0	1	0,8	4	1,6
Total investigations	23	100	99	100	126	100	248	100

Also, we did analyze these results from the point of view of the age, as well as for the size of the tumor.

In this way, as in patients up to 35 years and, in particular to 30 years, the mammographic investigation may be contraindicated due to glandular breast tissue without signs of pronounced metaplasia, the method of instrumental diagnosis in 85 patients was the mammary glands UGS. Thus, the correct conclusion of MGC presence was established in only 40 of the cases, which does not essentially improve the frequency of correct diagnosis, when compared to

clinical diagnosis.

Moreover, in patients up to 35 years the correct MGC conclusion was 27.3%, while between 35-49 years it was 39.5% and over 50 years it was 44.4% cases. Also, the MGC was suspected in 9.4% of the USG investigated patients, while 38.8% of the cases were concluded by the MFC and 7.1% by FA, 4.7% cases through solitary cyst presence.

Therefore, independently of age, the correct diagnosis of MGC by MG investigation was more informative than by USG investigation (tab. V).

TABLE V

Ultrasound findings in patients with stage I MGC, as depending to age.

USG Conclusions	The age of the patients						Total	
	< 35 years old		35 -49 years old		> 50 years old			
	11 patients investigated		38 patients investigated		36 patients investigated		85 patients investigated	
	No. abs.	%	No. abs.	%	No. abs.	%	No. abs.	%
Cancer	3	27.3	15	39.5	16	44.4	34	40.0
Cancer suspicion	2	18.2	1	2.6	5	13.9	8	9.4
MFC	4	36.4	17	44,7	12	33.3	33	38.8
FA	2	18.2	2	5.3	2	5.6	6	7.1
Solitary chistum	0	0	3	7.9	1	2.8	4	4.7

In addition, with regards to the tumor size, the MGC ultrasonographic diagnosis for tumor size < 0.5 cm proved to be correct in 25% cases with an informative value 2 times lower than that provided by mammographic investigation for tumors with the same dimensions, but 2 times more frequent by than clinical examination for tumor size of 0.5 - l.0 cm, where the diagnosis was correct in 37.8% cases and for tumor diameter between 1.1-2.0 cm - 46.7% cases (tab. VI).

TABLE VI

Ultrasonographic assessment for stage I MGC patients, as depending to the size of the tumor

USG Conclusions	Tumoral dimensions							
	< 0.5 cm		0.6-1.0 cm		1.1-2.0 cm		Total	
	8 patients investigated		37 patients investigated		30 patients investigated		75 patients investigated	
	No. abs.	%	No. abs.	%	No. abs.	%	No. abs	%
Cancer	2	25.0	14	37.8	14	46.7	30	40.0
Cancer suspicion	1	12.5	4	10.8	2	6.7	7	9.3

FA	0	0	3	8.1	2	6.7	5	6.7
Solitary chistum	2	25.0	1	2.7	1	3.3	4	5.3

DISCUSSION

Our results presented in this study, as seen through the 5-year survival, within each stage of the MGC are determined, firstly, by the type of applied treatment. This is very important, since the variant of applied treatment, the possibility for the administration of a neoadjuvant treatment depend on the informational value of the applied diagnostic methods.

Additionally, in the extended forms of MGC, ultrasound and mammography semiotics does not raise any difficulties and the correct conclusions could reach up to 92-98% cases.

Also, early forms of MGC semiotics in these two instrumental methods are rather poorly represented, which decreases the frequency of correct conclusions to 20.75% (Charafe-Jauffret et al., 2009). At the same time, the correct conclusions in the USG and MG investigations along with the clinical picture allow us to determine the exact place for the aspiration biopsy for cytological confirmation of the tumor process.

Additionally, another very important aspect of the present study referred to the selection for the prognostic decisive factors in the biological development variance of the tumoral process for the elaboration of optimal treatment schemes in stage I MGC.

In this way, it is generally accepted that the actual methods of MGC treatment which include the surgical component, radiotherapy, chemotherapy (CT) and hormone therapy (HT) could ensure a 90 - 95% rate of over 5 years survival in stage I of MGC (Leitner et al., 1995).

At the same time, the selection of the surgical intervention volume for the radiotherapy and chemotherapy place in the treatment of stage I MGC cannot be considered definitively determined. In this way, in several works of actuality the authors demonstrate that early stages MGC patients can be successfully cured only by surgical intervention (Baselga et al., 2009). Other researchers regard as mandatory the inclusion of radiotherapy and chemotherapy in the treatment schemes of early stages MGC patients (Colleoni et al., 2004).

Moreover, some authors considers applying radiotherapy only in patients which were subjected to organ saving surgery (Spooner et al., 1997), while others commented that in the cases of older patients aged over 55 years with tumors with sizes up to 2.0 cm, the mammary gland sectoral resection is effective without radiotherapy (Fisher et al., 2009).

For these reasons it is only generally recommended to perform chemotherapy in combination with radiotherapy for the action against the tumor pre-clinical metastases, especially since The Oncology Centers have not yet accumulated a sufficient number of randomized studies, in order to provide a meta-analysis sustained answer about the concrete treatment scheme for these patients.

In addition, establishing immunological hormonal homeostasis peculiarities depending on the degree of expression of molecular markers can be used to clarify the mechanisms of unfavorable clinical course in tumors with different degrees of expression of the RE, RP hormonal receptors and the HER2/neu molecular marker.

Moreover, within the international conferences in San-Gallen in 2005, 2007, 2009 on mammary gland cancer treatment, the criteria for the application of radiotherapy and chemotherapy in the MGC were discussed (McCloud et al., 2009).

In this way, as criteria for determining the treatment tactics of stage I MGC pa-

tients are considered the factors that characterize the tumor – the molecular markers indices, molecular receptors indices, tumor size and must be individually assessed.

Thus, in patients with tumor diameter < 1.0 cm and negative lymph nodes only the surgical treatment is recommended.

Also, although the literature data indicate increased frequency of hormonal disorders in MGC patients, the hormone therapy is yet limited to the indication of the anti-estrogens or progestins. In this way, it is necessary that hormonal therapy also include hormonal homeostasis regulation, since MGC patients may present hypothyroidism, hyperprolactinemia and other hormonal imbalances with various causes.

Also, it is necessary to take account of the immunological status particularities, because immunological status influences the results of treatment.

In addition, in the literature there are concrete data are about the fact that in MGC (including stage I), the degree of expression of molecular markers affects clinical development.

In this way, compared with stages II to IV, in stage I MGC, the expression of RE and RP is more pronounced (Rosen et al., 2009). This can be explained by the fact that, alongside the tumoral progression, the degree of tumor differentiation decreases.

Thus, this could represent an inverse relationship, as the low degree of differentiation contributes to high rates of tumor growth, which is why at the addressing point, these have a higher local or local/regional spread (Hughes et al., 2001).

CONCLUSIONS

MGC represents a polymorphic and pathogenic disease and it cannot be admitted that all subgroups of patients will obtain identical results from one tactic of treatment determined for all the patients with MGC. Thus, the concept of MGC both clinical and patho morphological, combines different cell clones depending on its microstructure and biology. As a result, the evolution of the disease, the prognosis and the effectiveness of the treatment may vary in different patients at the same stage, depending on the degree of malignancy of the tumor, its histopathological structure, the degree of expression of molecular markers identification and also immunoresistance.

CARDIAC PARAGANGLIOMAS

Extra-adrenal paragangliomas (PGLs) are uncommon neuroendocrine tumors. These tumors can originate from either the sympathetic or parasympathetic paraganglia. **Parasympathetic** PGLs are usually found in the head and neck region and do not release catecholamines. They are also referred to as nonchromaffin PGLs or chemodectomas in the literature. **Sympathetic** PGL, a synonym of pheochromocytoma, accounts for 0.1% to 0.2% of all patients with hypertension. This tumor is situated mostly along the sympathetic trunk in the abdomen, and exerts similar clinical and histopathological features as its adrenal counterpart. Less than 2% of PGLs are located in the chest, in which the cardiac PGLs (CPGLs) are extremely rare. The majority of these reports are single case studies or small series. CPGLs may develop catecholamine-related symptoms or respiratory obstruction symptoms. The tumors in most cases were found during imaging studies. It is rather difficult to clarify the accurate anatomical location via routine preoperative images such as computed tomography (CT) and echocardiography.In this review, in all reported cases were discussed clinical presentations, imaging findings, pathology, location, therapy, outcomes, and treatment patterns of CPGLs. The study found that most CPGLs were functional, preferably located in left retro-pericardium, and mostly fed by right coronary artery and left circumflex coronary artery. The combination of MIBG, MRI, and coronary angiography could well outline the lesions. Complete resection was the most effective strategy to cure this disease (Wang JG, Han J, Jiang T, and Li YJ. Cardiac Paragangliomas. *J Card Surg* 2015; 30: 55–60).

PYODERMA VEGETANS DEVELOPED ON CHRONIC LEG ULCER (Abstract): *Pyoderma vegetans* is a rare disorder that more commonly affects middle-aged persons, with a male predilection. It is characterized by vegetating lesions that coalescence into a plaque with eroded surface, covered by purulent discharge and crusts. The etiology of this disease is not known with certainty, but it is often associated with bacterial infections in immunocompromised patients. We report the case of a 73-year-old men who presented to the Iasi Dermatology Clinic with a large, irregular, relatively well-defined dermohypodermic ulcer, with infiltrated sclerosing borders, accompanied by pain, with the floor covered in the Northern part by a proliferative, vegetative bleeding area, and the rest by a yellowish secretion and cellular debris, located on the left leg. Bacteriological examination of ulcer secretion identified *Pseudomonas aeruginosa*. Anatomopathological examination confirmed the development of *Pyoderma vegetans* on chronic leg ulcer. Under specific treatment for chronic leg ulcer and eradication of infectious focus the outcome was favorable both in terms of trophic ulcer scarring and *Pyoderma vegetans* healing. **Keywords**: PYODERMA VEGETANS, CHRONIC LEG ULCER.

Pyoderma vegetans is a rare condition, first described by Hallopeau in 1898 (1); it is more common in middle-aged persons and there is a male predilection (5). *Pyoderma vegetans* is clinically characterized by vegetating lesions that coalescence into a plaque with eroded surface, covered by purulent discharge and crusts (2). It can occur at any level, but there is a predilection for limbs and infected loss of substance, traumatic or of any other nature (2, 3). The etiology of this disease is not known, but is often associated with bacterial infections in immunocompromised individuals (3, 4, 5, 6). *Pyoderma vegetans* has been associated with ulcerative colitis (7, 8), T-cell lymphoma (9), and alcoholism with malnutrition (10), HIV infection (11), chronic myeloid leukemia (12) and lupus nephritis (13).

CASE REPORT

We present the clinical case of a 73-year-old male patient residing in a rural area, who presented to the Iasi Dermatology Clinic with a large, irregular, relatively

well-defined trophic ulcer, with infiltrated sclerosing borders, intensely vegetative, bleeding area in the Northern part, located on the left leg. The patient had both a family history (mother) and personal history of chronic venous insufficiency.

The patient was known with chronic venous insufficiency and superinfected chronic left leg ulcer since age 48 years old, with a fluctuating course (ulcer decreased in size or increased in size and depth), and therapeutically neglected. The patient said he noticed during the last year an intense proliferation of the floor of ulcer, bleeding and pus discharge.

Dermatological physical examination revealed on the left leg a large dermohypodermic ulcer (15 X 10 cm), irregular, relatively well-defined, with infiltrated sclerous borders, painful, the floor covered in the Northern part by a proliferative, vegetative, bleeding portion, and the rest by an yellowish secretion and cellular debris (fig. 1).

Fig. 1. Trophic ulcer with a vegetative Northern area

The ulcer was surrounded by a painful erythemato-edematous placard, imprecisely defined, inflammatory signs present, covered here and there by crusts. Asymptomatic erythematous macules, violet-colored and hyperpigmented, isolated and coalesced into plaques, that did not disappear on vitro pressure were present on both legs.

Laboratory findings were: inflammatory syndrome, mild hyperglycemia and presence of *Pseudomonas aeruginosa* in ulcer discharges. Venous Doppler ultrasound did not detect any signs of superficial and deep vein thrombosis in the lower limbs. Skin biopsy revealed a fragment with deep ulceration, covered by necrotic debris with leukocytes and granulation tissue, epidermis at ulcer edges is uneven with papillomatous thickening and subjacent dermis with abundant polymorphous inflammatory infiltrate.

The findings of local physical examination and laboratory investigations corroborated the following positive diagnoses: chronic venous insufficiency CEAP class VI, trophic left leg ulcer superinfected with *Pseudomona aeruginosa*, *Pyoderma vegetans* on the left leg, periulcer cellulitis, stasis dermatitis.

Treatment consisted in surgical debridement by scalpel excision of the slough followed by systemic drug therapy (antibiotic according to antibiogram, phlebotropic and vasodilator agents) and topical drug therapy (periulcer dermo-corticoid, nitration of vegetative lesions with 1% silver nitrate crystals for the beginning and then, silver nitrate ointments as daily dressings) in combination with rigorous local hygiene with water and dermatological soap and avoidance of prolonged standing.

Under proper treatment, the course was favorable with an approximately 50% ulcer closure within 30 days, flattening and progressive disappearance of *Pyoderma vegetans* lesions after the infectious focus was cleared up (one-month bacterial examination was negative), and periulcer erythema-

tous placard gradually diminished to disappearance (fig. 2, 3).

Fig. 2. Ulcer appearance after 30 days of treatment

Fig. 3. Ulcer appearance after 4 months of treatment

DISCUSSION

Venous ulcer is the most severe manifestation of chronic venous insufficiency, being a substance loss secondary to trophic skin changes due to venous stasis (14). It affects the lower third of the leg, with a predilection for the left leg (47%). It is associated with ochre and purpuric dermatitis, sclerodermiform dermo-hypodermimitis, eczematiform dermoepidermitis, and more rarely with white atrophy and thrombophlebitis (14). The main complication of venous ulcer is a secondary bacterial infection (2). Often, bacteriological examination of ulcer discharge reveals gram-positive bacteria, such as *Staphylococcus aureus* in about 56% of cases, and gram-negative bacilli, such as *Pseudomonas aeruginosa* and *Proteus* (3).

It was suggested that *Pyoderma vegetans* is a response to massive bacterial colonization or epidermal invasion in an immunocompromised patient (15). The most common microbial agents isolated are staphylococci and beta-hemolytic streptococci. Other suspected agents are *Klebsiella spp*, *Bacteroides spp*, enterococci, *Pseudomonas aeruginosa* and *Corynebacterium spp* (5, 16). A case associated with *Trichophyton mentagrophytes* has also been reported.

Some authors believe that the microbiological agent is not primarily responsible for the disease and the infection develops secondary to an immune dysfunction. In support of this theory, in some of cases serum immunoglobulin levels were decreased and phagocytic dysfunction was observed (5, 16, 17).

The association of chronic venous ulcer with and *Pyoderma vegetans* is rare.

The diagnosis of the disease depends primarily on the exclusion of other diseases that can present as chronic vegetative lesions, including squamous cell carcinoma, Kaposi disease, achromic malignant melanoma, tuberculosis vegetans, pyoderma gangrenosum, and pemphigus vegetans (4, 5, 8). The histopathological characteristics of *Pyoderma vegetans* are pseudoepitheliomatous hyperplasia, and the presence of numerous abscesses both in the hyperplastic epidermis and dermis. The abscesses may contain neutrophils or eosinophils (4, 5).

Pyoderma vegetans lesions can heal spontaneously, but usually recur and become chronic. There are no standard treatment modalities. The literature emphasizes the importance of treating the underlying

disease (5). Thus, the treatment of *Pyoderma vegetans* occurring on a chronic leg ulcer is primarily based on venous ulcer therapy.

The three phases in the management of venous ulcer are: cleansing and debridement, granulation phase, and epithelization and healing. Debridement is commonly performed to remove slough, eschar and bacterial biofilms from the ulcer bed with the aim of increasing wound healing. The most common commonly used are: surgical debridement using scalpel, scissors or curette, which is the most rapid and precise, but can be painful, and autolytic or enzymatic debridement, which are slow and can be facilitated by the use of moisture-donating dressings or protease preparations, respectively. Granulation tissue must be kept permanently moist. It is used a hydroactive wound dressing that provides a moist wound environment for optimal healing, thus being highly effective in the granulation phase. During the epithelialization phase dressings are applied to make sure that moisture is retained over a wound. Hydroactive ointment dressing, hydrogel dressing, or hydrocolloid dressing (designed for already epithelized wounds) are the best choices (3, 14).

No standardized treatment plan for *Pyoderma vegetans* is available, although antibiotic therapy has been frequently used with variable results. Good results have been reported in the literature when administering the following associations: intravenous ceftriaxone and topical aluminum acetate soaks, ampicillin and x-ray radiation, ciprofloxacin and fluocortolone, and etretinate and systemic corticosteroid therapy (4, 5).

CONCLUSIONS

In the reported case, the diagnosis of *Pyoderma vegetans* is both clinical and bacteriological, and anatomopathological. The outcome was favorable with both chronic leg ulcer and *Pyoderma vegetans* healing.

FUSARIUM MYCOTOXINS DIETARY INTAKE THROUGH BEER CONSUMPTION IN EUROPE

Mycotoxin contamination of food and beverages represents a serious world-wide problem. Mycotoxins are secondary metabolites naturally produced by various species of fungi, including *Fusarium* genus. Deoxynivalenol is the most widely detected mycotoxin in the cereals used in beer industry. Mycotoxins are thermally stable and present a good water solubility, therefore the contamination of beer might occur in any step of the brewing process. Mycotoxins are incriminated for their hepatotoxic, carcinogenic, nephrotoxic, neurotoxic and immunosuppressive effects. Although deoxynivalenol was not classified by the IARC as being carcinogen to humans, it is still responsible for a series of deleterious effects for the organism such as: weight loss, endocrine dysfunctions and immune alterations. Rodríguez-Carrasco *et al*. determined the content of 14 *Fusarium* toxins and their metabolites in a total of 154 beer samples produced in Europe, in order to estimate the dietary intake of these mycotoxins. For this purpose, they developed an analytical method which consisted in a QuEChERS (Quick, Easy, Cheap, Effective, Rugged, Safe) extraction technique followed by gas chromatography-tandem mass spectrometry analysis; the analytical method was validated. Only two mycotoxins were found in a high number of beer samples: deoxynivalenol in 59.7% of samples and HT-2 toxin in 9.1 % of samples. However, their average concentrations (17.2 μg/L for deoxynivalenol and 2.8 μg/L for HT-2) represent only 5% of the deoxynivalenol PMTDI (provisional maximum tolerable dietary intake) and 7-12% of the HT-2 TDI (tolerable dietary intake) for European population. The authors concluded that a moderate consumption of beer does not pose any health risk for the Europeans. Nevertheless, beer consumption represents a significant mycotoxin source for heavy beer drinkers (Rodríguez-Carrasco Y, Fattore M, Albrizio S, Berrada H, Manes J. Occurrence of *Fusarium* mycotoxins and their dietary intake through beer consumption by the European population. *Food Chem* 2015; 178: 149-155)

HISTOPATHOLOGICAL DIAGNOSIS CRITERIA IN ENDOMETRIAL HYPERPLASIA (Abstract**):** Endometrial hyperplasia is a condition of the abnormal proliferative lesions of the endometrium. **Aim**: To highlight the value of histopathological examinations with assessment of the ways to obtain endometrial biopsies and the appreciation of the contribution of different histopathological techniques that can be used to establish a correct and complete diagnosis. **Material and methods:** The study was conducted in a group of 50 patients diagnosed with endometrial hyperplasia. In all cases the bioptic curettage was performed using a curette to obtain more abundant material for the histopathological examination. **Results**: Histopathological diagnosis guides the therapeutic attitude and has an important prognostic value. The study group was characterized by histoarchitectonic heterogeneity, presented even in the same case. Histoarchitectonic and cytological changes differentiate endometrial hyperplasia from physiological proliferative endometrium. **Conclusions**: The diagnosis of certainty between the four types of endometrial proliferation established by the WHO can only be done through the histopathological examination. **Keywords:** HISTOPATHOLOGICAL EXAMINATION, ENDOMETRIUM, HYPERPLASIA.

In the female genital apparatus, the endometrium undergoes cyclic proliferation, differentiation, degeneration and regeneration, processes regulated by the hypothalamic-pituitary-ovarian axis. The disruption of this cyclical development leads to the occurrence of dysfunctional uterine bleeding, which often has endometrial hyperplasia as morphological substrate.

The endometrial cycle undergoes physiological changes with age. Perimenopause and post menopause affects the endometrial cycle, female gonads and have a systemic impact. Hormonal imbalances also lead to morphological and functional changes in secondary sexual characteristics (1). In this context, the "aging face" phenomenon is accelerated due to the faster loss of subcutaneous supportive adipose layer and a decrease in quality of fibrous connective structures.

Endometrial hyperplasia represents abnormal proliferative lesions of the endometrium, leading to increased mucosal thickness, alterations in glandular architecture and changes in the gland-to-stroma ratio

(2). The lesion is hormone-dependent, and as a result it is reversible, but can progress to an invasive carcinoma in the presence of genetic changes that cause a monoclonal glandular proliferation (3). A category of patients with endometrial proliferation consists of those with a congenital malformation of the uterus. This type of malformation correlates with the concomitant existence of one or more malformations at other levels.

There are two types of hyperplasia, an atypical one, closely related to adenocarcinoma and a nonatypical one, which is little linked with the carcinomatous lesion (4). The notion of simple endometrial hyperplasia refers to nonatypical hyperplasia without glandular architectural abnormalities, whereas complex glandular hyperplasia defines nonatypical hyperplasia with abnormalities of glandular architecture (5). The presence of cytological atypia is the most important factor related to progression to cancer, especially in postmenopausal women (6).

The high degree of morphological variability of endometrial proliferation, even within the same tissue sample, is responsible for the difficulty in defining and establishing clinical and morphological diagnostic criteria. All forms of hyperplasia present certain morphological features showing an increase in gland-to-stroma ratio, irregularities in the shape and the size of the gland.

The macroscopic examination usually reveals an enlarged uterus and, on the hysterectomy specimens the endometrium is pale, diffuse thickened or polyploid, with a smooth, velvety or granular surface (7).

The microscopic examination highlights architectural alterations, characterized by glandular complexity and the amount of stroma that separates the glands, distinguishing simple and complex forms of hyperplasia, regardless of the presence of atypia.

Hyperplasia without atypia represents excessive proliferative response to uncompensated estrogen stimulation. The endometrium responds in a diffuse way with a balanced increase of both glands and stroma (10). *Simple hyperplasia* usually involves the entire endometrium with a diffuse thickening of the endometrium. Microscopically appears glandular proliferation with irregular shapes and sizes, separated by abundant stroma. *Complex hyperplasia* presents a disordered glandular proliferation, to the detriment of the stroma. The endometrial glands are agglomerated with an increase in architectural complexity separated by a relatively reduced stroma, the gland-to-stroma-ratio is 3/1 (8).

Atypical hyperplasia is distinguished from the precedent by cytological atypia of the glandular epithelium, represented by the loss of axial polarity, nuclear pleomorphism that often has irregular contours, prominent nuclei and distinct or dense chromatin. Atypia appears almost always focal.

MATERIAL AND METHODS

The study was conducted in a group of 50 patients aged 24 to 70 years, diagnosed with endometrial hyperplasia admitted to the Iasi "Cuza-Voda" Hospital. All patients underwent comprehensive clinical and laboratory investigations, and the certainty diagnosis was based on the histopathological examination of bioptic curettage or surgical specimens.

The routine general physical examination has been supplemented in many cases with specialized examinations (gastrointes-

tinal, cardiovascular, renal, etc.). In all cases the bioptic curettage was performed with the curette to obtain more abundant material, the practice demonstrating that the aspiration method is a less favorable opinion. The specimens were embedded in paraffin, then special stains were made: hemalums-eosin, tri-color van Gieson, periodic acid-Schiff (PAS) coloring.

RESULTS

The histopathological examination of the collected fragments aims to identify the nuclear changes occurring at the cytological level and to assess the degree of their diffusion.

Approximately 2/3 of the studied cases were identified with simple endometrial hyperplasia. Young women, up to 40 years of age, had heterogeneous histopathological aspects with simple hyperplasia zones with average glandular density; the glands retain their regular contour and circular lumens. In the same cases, it appeared on sections glands with irregularly contoured, even with a corrugated lumen (fig. 1).

Cases which has a high-density gland have an uneven and narrow lumen (fig. 2).

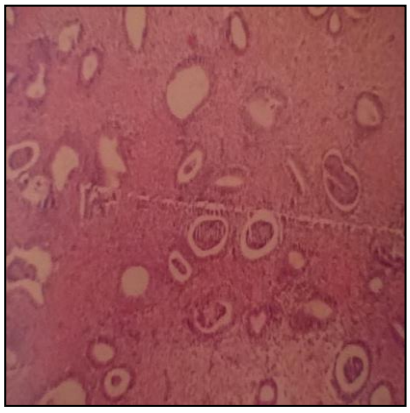

Fig. 1. Simple hyperplasia, regular contour glands and medium frequency; HE 20x

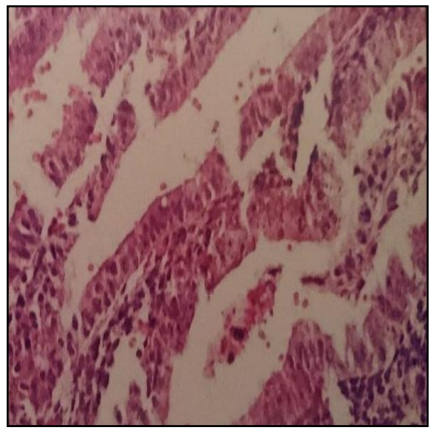

Fig. 2. Endometrium with simple hyperplasia; HE 40x

The endometrial epithelium appears simple, prismatic, tall, with fusiform nuclei perpendicular to the basal membrane (fig. 3). These glands may have endoluminal papillary proliferations.

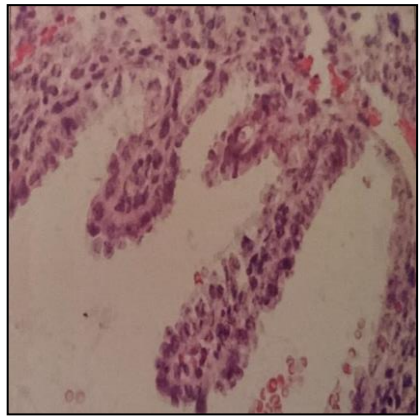

Fig. 3. Endometrium with dilated gland and papillary proliferation; HE 40x

The surface epithelium presents a decrease in height inversely proportional to age. The epithelia of older people have a homogeneous appearance, starting from glands with irregular shape and wide lumen in the premenopausal and going to areas

with regular appearance and narrow lumen in older people. In this situation, intraluminal proliferation persists.

One third of the studied cases had complex hyperplasia. This type of hyperplasia has a characteristic appearance of the glands, arranged back to back and separated by a minimal thickness stroma. Their lumens are extremely irregular due to the significant endoluminal papillary proliferation (fig. 4).

Fig. 4. Complex endometrial hypertrophy, with rare intraluminal proliferation; HE 40x

The glands also exhibit many cystic dilations that give the appearance of heterogeneity. Characteristic of this type of endometrial proliferation is the existence of glandular branches and even intergranular communication.

In both forms of hyperplasia, there is a degree of stromal fibrosis directly proportional to the age of the patient.

DISCUSSION

The importance of this study is revealed by the fact that it is unanimously accepted (9) that simple endometrial hyperplasia may progress to atypical endometrial hyperplasia, the latter being considered precancerous status. In the classic diagnosis of endometrial hyperplasia, the gland-to-stroma ratio is used.

Histopathological diagnosis guides the therapeutic attitude and has an important prognostic value. The study group is characterized by a histoarchitectonic heterogeneity. Characteristic from this point of view are the variety of shapes and glandular diameters and the intraglandular ramifications. The diagnosis of certainty of simple endometrial hyperplasia by the gland-to-stroma ratio should ideally be made between days 10-14 of the physiological endometrial cycle.

Another histopathological criterion of differentiation of the two types of hyperplasia is related to the structure of the gland, which in simple hyperplasia must be tubular, right and without branches. Variations in contour and lumen diameter occur in both types of hyperplasia.

Complex endometrial hyperplasia is histopathological diagnosed, primarily by the loss of individuality of the flanders, with the appearance of intergranular branches and communications. The type of atypical complex proliferation is marked by the existence of papillary proliferations of the glandular epithelium. Also, the epithelium appears arranged in a pseudo-stratified or even stratified form. Complex hyperplasia may present elongated cells with “cane-like” nuclei arranged in narrow bundles. Between stromal cells may be present clear cells, these being lipid-containing macrophages (10).

The presence of nuclear atypia by increase in nuclear volume and change in the nuclear/cytoplasmic ratio with budding of the core, thickening of its membrane, and the coagulation of chromatin are criteria of proliferative atypia. The nucleus migrates to the geometric center of the cell, and the cytoplasm acquires a basophilic appearance. These are malignant or premalignant changes and call into question the differen-

tial diagnosis between endometrial carcinoma and well-differentiated epidermoid carcinoma (11, 12, 13, 14). The histopathological differentiation criteria of the two possible diagnoses refer to the fact that in endometrial carcinoma papillary proliferations are extremely pronounced, with atypical cells and mitosis, and the glands get a cribriform aspect

In neither of these two situations a secretory glandular epithelium was found, no matter the age of the patient.

Another important aspect we watched was the perilesional vascularization. As in other neighboring neoplasms, such as rectal cancer, peritumoral vascular branches acquire characteristic, proliferative aspects of paraneoplastic neovasculogenic (15). These aspects have been noticed by using the PAS reaction to reveal the basal glandular membrane.

CONCLUSIONS

Endometrial hyperplasia is a non-invasive, non-physiological, estrogen-dependent endometrial proliferation. In our study results that histoarchitectonic and cytological changes differentiate endometrial hyperplasia from the physiological proliferative endometrium. The diagnosis of certainty between the four types of endometrial proliferation established by the WHO can only be done through the histopathological examination.

NEWS

HYPERCHOLESTEROLEMIA – GENETIC DISEASE

Hypercholesterolemia is a common disorder which was reported in 39% of the worlds' adult population in 2008. Most of the patients with familial hypercholesterolemia (FH) have a mutation in the LDLR gene which is dominantly inherited. Mutations in the APOB and PCSK9 genes accounts for a smaller percentage of autosomal dominant FH. This review explored the recent evidence of association of the genetic variants with hypercholesterolemia and the 3 lipid traits: total cholesterol (TC), HDL cholesterol (HDL-C) and LDL-C and the biological effects of these genes in lipid homeostasis. The focus is mainly on the genes with a recognized or a potential role in lipid metabolism for which the association with the serum lipid traits; TC, LDL-C and HDL-C was observed in candidate gene association studies, genome-wide association studies (GWAS), genetic linkage studies and other studies with a case–control design. These include the genes encoding apolipoproteins, lipoprotein receptors and receptor related proteins, lipid transporters and lipid transfer proteins, the enzymes and proteins with a regulatory role in lipoprotein metabolism as well as the proteins that regulate the expression of those genes. The function of these genes in lipid metabolism and the association of single nucleotide variants (SNVs) in these loci with serum lipid traits, are not yet clearly identified. In summary, GWAS and meta-analyses have identified over 190 SNVs associated with serum TC, LDL-C and HDL-C levels in about 60 genes. Fourteen non-synonymous coding variants were identified in 10 genes that accounts for 7% of the variants in lipid related genes described in GWAS. Significant challenges remain. The known genes account for only a proportion of the cases and a substantial amount of missing heritability still exists (Paththinige CS, Sirisena ND, Dissanayake VHW. Genetic determinants of inherited susceptibility to hypercholesterolemia – a comprehensive literature review. *Lipids in Health and Disease* (2017); 16:103).

NAPKIN PSORIASIS- CASE REPORT (Abstract): Psoriasis is a chronic inflammatory disease that can affect up to 1% of children. Genetic (family history of psoriasis) and environmental factors (bacterial or viral infections, stress, and trauma) are frequently involved in its occurrence. Napkin psoriasis is a particular form of psoriasis affecting mainly children younger than 2 years of age and can be classified together with other diseases under diaper rash. We present the case of a 4-month-old infant, born at term, naturally, weight and height within the normal range, who was brought to the Dermatology Clinic for the occurrence of erythematosquamous lesions in the anogenital area, buttocks and upper third of the thighs, with subsequent dissemination of lesions. The onset of symptoms began a few days after a respiratory tract infection. Initially he received treatment with systemic antibiotic and topical corticosteroid and antibiotic with unfavorable outcome. Laboratory tests revealed iron-deficiency anemia, leukocytosis, thrombocytosis, accelerated ESR, marked hepatic cytolysis, hyperphosphatemia and nasal carriage of Staphylococcus aureus. A systemic antihistamine and nonspecific desensitization treatment was administered. Topical treatment consisted in the removal of predisposing factors and irritants (diaper, urine) by rigorous hygiene, application of topical non-fluorinated corticosteroid and use of emollients, with favorable course of the lesions. The peculiarity of the case is that the diagnosis of psoriasis was based on history, physical examination and laboratory tests, in the absence of a pathology examination to confirm the diagnosis. Pathology examination could not be performed due to patient's age as biopsy required general anesthesia. **Keywords**: PSORIASIS IN CHILDREN, NAPKIN PSORIASIS, DIAPER RASH

Psoriasis is a chronic inflammatory disease affecting the growth and differentiation of the epidermis, with polygenic predisposition and various triggering factors (infections, medicines, physical or mental trauma, stress) (1). It evolves through successive bouts with a high individual variability in frequency. Although less common in children than in adults, the frequency of psoriasis at early ages remains quite high.

In approximately one third of patients the onset is during the first 20 years of life (2). In 25-45% of patients the disease starts before age 16 years, 10% before age 10 and 2% before age 2 (2). Studies conducted in Denmark and India reported onset between age 6 and 10 in most patients, whereas according to studies conducted in Australia and the Middle East the onset was before age 4. Congenital psoriasis with onset at birth or during the first days of life is very rare. Plaque psoriasis is the most common form both in adults and in children (68.6% of cases). However, initial lesions in children may be fewer and less scaly and thus difficult to diagnose in some cases. In a study conducted in China guttate psoriasis was found in 28.9% of patients, erythrodermal psoriasis in 1.4%, and palmoplantar pustular psoriasis in 1.1% of children (3). There are differences regarding sex distribution between various reports. Some authors believe that it is more common in women (4, 5), as in adults (6), others believe that gender distribution is relatively equal in children (7, 8, 9). Psoriasis may occur in newborns and infants and is difficult to diagnose due to the particular clinical features. Newborns and infants mainly develop the so-called napkin psoriasis or diaper psoriasis characterized by anogenital lesions, the diaper area, as an intensely erythematous placard, slightly scaly, dry, and well-defined. According to data reported by Morris *et al.* (8) this form of psoriasis is most common in children under two years of age.

CASE PRESENTATION

We present the case of a 4-month-old male infant residing in a rural area admitted to the Dermatology Clinic of the Iasi "Sf. Spiridon" Emergency Hospital for the emergence of a placard erythemato-squamous in the anogenital area, buttocks and upper third of the thighs. From patient's personal history we found that he was born at term, naturally, birth weight 3000 g, height 50 cm, APGAR score 9, with favorable postnatal development, breast-fed for one month then formula-fed, vaccinated according to the immunization schedule, but the prophylaxis of rickets with vitamin D3 incorrectly administered. From the previous medical history we mention acute nitrite poisoning at age 2 months.

The skin disease started approximately 2 weeks before admission as a symmetrical erythematosquamous placard with well-defined margins in the anogenital area, buttocks and upper third of the thighs (fig.1) with local discomfort at diaper changing and washing the genitals expressed by crying and restless. The rash appeared a few days after the onset of respiratory symptoms (rhinorrhea, initially watery then mucopurulent, cough, low-grade fever, and change in bowel habits). Shortly after, plaques and placards with the same features appeared at distance (armpits, elbow crease bilaterally, anterior and posterior neck, scalp, anterior and posterior thorax, periocular and retroauricular regions). Home treatment was initiated by the family physician, consisting in antibiotics, calcium gluconate and topical dermocorticosteroids and antibiotic ointment for 5 days with unfavorable outcome. Because skin lesions persisted the mother decided to seek specialist advice at the Dermatology Clinic.

On admission the infant was afebrile, eutrophic, weighed 7,500 g, was 62 cm tall, and his general health status was slightly impaired. General physical examination at admission revealed a superficial physiological generalized microadenopathy, pale tint to the skin and mucous membranes, tempo-

ro-occipital craniotabes, anterior fontanelle 3/4 cm in diameter, with sagittal dehiscence, normotensive, closed posterior fontanelle, seromucous rhinorrhea, rare nonproductive cough, symmetric rib cage excursions, RR = 40/min, systolic murmur grade II-III / 6 to the base of the heart and apex, HR = 130 min. On local examination the following were seen: erythemato-squamous plaques and placards, well-delimited, covered by pearly-white thick, multi-layered scales, Auspitz signs present at Brocq methodic scaling, located in the anogenital area, buttocks, inner thighs, axillary region, elbow crest bilaterally, peri-ocular region bilaterally, lower third of the abdomen, and posterior thorax (fig. 2, 3).

Fig. 1. Erythematosquamous placard in the anogenital area, buttocks and upper third of the thighs

Fig. 2, 3. Erythematosquamous plaques and placards located in the anogenital area, buttocks, inner thighs, trunk, face, limbs

Laboratory findings:

- Iron-deficiency anemia (serum iron = 23mg/dL).
- leukocytosis (26,190 / mm^3).
- marked hepatic cytolysis (ALAT = 266U/L, ASAT = 133U/L), drug-induced.
- hyperphosphatemia (P = 6.28 mg/dL), and high ALP (760UI/l), in the context of

deficiency rickets.

- thrombocytosis (T = 723,000 mm^3).
- VSH acceleration (17mm/h, 43mm/2h).
- nasal exudate: Staphylococcus aureus carriage.

Although the diagnosis of psoriasis is confirmed by pathological examination, this could not be performed due to patient's age as biopsy required general anesthesia. Typical clinical appearance of the lesions, history and laboratory tests were enough to make the diagnosis of napkin psoriasis.

Systemic treatment with antihistamines and nonspecific desensitization treatment, removal of local predisposing factors and irritants (diaper, urine) by rigorous hygiene, application of topical nonfluorinated dermocorticosteroids gradually tapered to avoid rebound phenomenon and use of emollient wash gels, bath emulsion and face and body creams were initiated. The course was obviously favorable since treatment day 2 with significant improvement of skin lesions (fig. 4), the baby being much quieter. At discharge the patient was referred to a pediatrician for the assessment and treatment of respiratory disease, anemia, deficiency rickets and the other changes detected by laboratory tests.

Fig. 4. Improved appearance of lesions after 2 days of treatment

DISCUSSION

The clinical forms of pediatric psoriasis are the same as in adults: plaque, guttate, pustular, erythrodermic, reverse, arthropathic. Usually children have a family history of this condition, according to Morris *et al.* (8) 71% of patients having a family history. Genetic and environmental factors are incriminated in the development of psoriasis in children. The lesions are clinically similar to those in adults: well-delimited erythematosquamous plaques and placards, positive Auspitz sign, but initial lesions may be less scaly and less infiltrated than in adults. Another difference is that in children the lesions are usually symptomatic, itchy, and the prevalent locations are the scalp, extensor surface of the limbs, trunk, face and ears. A particular form is located in the diaper area, being reported in 45% of children aged less than two years.

The ocular involvement is noticed in one third of the patients with psoriasis. Dry eye, conjunctivitis, episcleritis and anterior uveitis are the most frequent findings. No ocular signs have been noticed in our patient.

In newborns and infants diaper area is a unique topographic region in terms of skin lesions, as multiple diseases prevalently occur at this level, all called diaper rash. According to some authors diaper rash can be classified into three categories (10): diseases caused directly or indirectly by the wearing of diapers (candidal intertrigo, irritant contact dermatitis), lesions located elsewhere, but can be exaggerated in the groin area due to the irritating effects of wearing a diaper (atopic dermatitis, seborrheic dermatitis, psoriasis), and lesions that appear in the diaper area irrespective of diaper use (bullous impetigo, Langerhans cell histiocytosis, *acro-dermatitis entero-*

pathica, congenital syphilis, scabies). Often the positive diagnosis is based only on history and physical examination, the clinician being faced with difficulty in making a correct diagnosis. In the case of recalcitrant diaper dermatitis on the groin, unresponsive to treatment, a possible diagnosis of psoriasis should be suspected.

CONCLUSIONS

The occurrence of psoriasis in children is possible, but few cases have been reported in infants. Although it is recognized that the onset of psoriasis in children is more common in families with psoriasis, in the here presented case the genetic component could not be demonstrated. Although initially difficult to make a certain diagnosis, through careful and thorough history (with the help of the mother), clinical and laboratory assessment we concluded that our patient had a form of psoriasis- napkin psoriasis. Key factors in triggering psoriasis are bacterial, viral or fungal infections. In our patient the incorrectly treated respiratory infection led to impaired liver function and favored the appearance of psoriasis. Treatment of psoriasis in children requires special attention and close cooperation between the dermatologist, pediatrician and parent, this triad being the key to successful treatment. The diagnosis of psoriasis is based on clinical criteria, no specific laboratory tests being available except for pathology examination, which in newborns and infants is difficult to perform as it requires general anesthesia. These young patients should be followed-up closely, parents should be informed about the disease and its possible progression; in some cases it progresses to pustular psoriasis, and in 15% of cases the children will develop other forms of psoriasis in later life.

MAIN NEUROENDOCRINE FEATURES, DIAGNOSIS AND THERAPEUTIC POSSIBILITIES IN THE CRONIC FATIGUE SYNDROME, AN UNDERDIAGNOSED ENTITY (Abstract): Chronic fatigue syndrome is characterized by severe, persistent fatigue which is not relieved by rest and is not associated to other medical conditions. Other common symptoms are including concentration and memory impairment, muscle and multiple joints pain, extreme exhaustion after physical or mental exertions, irritable bowel syndrome-like symptoms and depression, anxiety, mood swings and panic attacks. Etiology of the syndrome is not yet clear, post-viral and stress hypotheses were not verified. Diagnosis is confirmed in case of new onset of severe fatigue, for six consecutive months or more; fatigue is leading to significant reduction of the activity levels and is accompanied by other four or more of the specific associated symptoms, which are also lasting for six months or longer. The management of the disease is based on cognitive behavioral therapy, graded exercise therapy and pacing; medication plays a minor role in therapy. The occupational status is severely affected, more than half of the cases being unable to work. Full recovery rate is in average of about 5 %. **Keywords:** CHRONIC FATIGUE SYNDROME (CFS), HYPOTHALAMIC-PITUITARY-ADRENAL AXIS (HPA axis), HYPOCORTISOLISM

Chronic fatigue syndrome (CFS) is the term used to define a significantly disabling medical condition, characterized by persistent fatigue and other troubling symptoms which are lasting at least six months in adults and three months in children or adolescents. The fatigue is not due to exertion, is not relieved by rest and is not tributary to other medical conditions (1). Other terms used to designate the syndrome are myalgic encephalomyelitis or post-viral fatigue syndrome. Although genetic, infectious and psychological hypotheses were proposed, the etiology of CFS is not known and data are supporting the idea that the syndrome should have multiple causes (2).

In 1934, an out-break of a then so-called atypical poliomyelitis took place at the Los Angeles County Hospital; numerous doctors and nurses were affected and the disease resembled a lot with what is now described as chronic fatigue syndrome. In 1955, another out-break at the Royal Free Hospital in London was called benign myalgic encephalomyelitis. The term of chronic fatigue syndrome was first introduced in 1987 (3).

NEUROENDOCRINE FEATURES, POSSIBLE ETIOLOGY

Main endocrinological research findings in chronic fatigue syndrome are mild hypocortisolism, a blunted adrenocortico- tropin (ACTH) response to stressors and enhanced negative feed-back sensitivity to glucocorticoids. Yet, there is no specific or uniform dysfunction of the HPA axis in CFS and approximately half of the relevant studies did not show evidence of hypocortisolism, or of an abnormal response to various types of challenge tests.

Prospective studies suggest that HPA axis is not a factor involved in the pathogenesis of the early stages of CFS, but it is believed that it might play a role in perpetuation and enhance of the symptoms later on, in the course of the disease (4).

A 2011 meta-analysis evidenced a mild but statistically significant hypocortisolism in chronic fatigue syndrome; hypocortisolism being associated with a weaker response to cognitive behavioral therapy (5).

At the level of the central nervous system, a hyperserotonergic state and hypoactivity of the HPA axis are characteristic, but still there is no answer if these abnormalities are a cause or a consequence of the syndrome. Alterations in serotonin signaling can develop physiologic and behavioral changes in these subjects (3).

Polymorphism in genes encoding serotonin pathways may show genetic predisposition in the pathophysiology of CFS. Gene-related dysfunction of HPA axis which regulates the stress response might be involved in CFS (6).

A prospective study found that after viral and non-viral infections, some of the cases met the criteria for CFS, concluding that post-infective fatigue syndrome is a valid model for the investigation of one possible pathway to CFS. Nevertheless, prevalence and roles of both infection and stress in the etiology of the syndrome are not known (7).

All racial and ethnic groups are affected by the disease; lower income groups of population show a slightly higher risk to develop chronic fatigue syndrome. Between 60 and 85 % of cases of CFS are women but it seems that the prevalence among men is underreported. The disease is occurring more frequently between the ages of 40 and 59; CFS is developing more rarely among children and adolescents than among adults. Blood relatives of people with chronic fatigue syndrome seem to be more predisposed to develop the disease than the rest of the population (7, 8). National health organizations estimated that more than one million Americans and a quarter of a million people in the UK have chronic fatigue syndrome; even more, it is estimated that approximately 80 % of the existing cases are undiagnosed (8).

DIAGNOSIS

The onset of CFS is abrupt, frequently accompanied by a flu-like illness, while a large number of cases begin with several months of severe adverse stress (9).

The three most important diagnosis criteria are: a new onset of severe fatigue for six consecutive months or more, not related to effort, not substantially relieved by rest and which is not determined by other medical conditions; the fatigue is the cause of significant reduction of the previous activity levels. These criteria are associated with four or more of the following symptoms, lasting six months or longer: post-exertion malaise, physical or mental effort bringing on extreme, prolonged exhaustion and sickness; impaired memory or concentra-

tion, unrefreshing sleep; muscular pain, multiple joints pain, headaches of a new type or more severe, recurrent sore throat, cervical or axillary tender lymph nodes.

Other common symptoms are: brain fog, difficulty in maintaining orthostatic condition (dizziness, balance problems or fainting); irritable bowel syndrome-like symptoms, such as bloating, stomach pain, constipation, diarrhea and nausea; chills and night sweats; visual disturbances (sensitivity to light, blurring, eye pain); allergies or sensitivities to foods, odors, chemicals, medications or noise; depression, anxiety, panic attacks, mood swings. Cognitive symptoms are especially deficits of attention, memory and reaction time. Processing speed of complex and simple information is impaired (10, 11).

A common diagnosis of CFS is characterizing a disease in which functional capacity of the affected subjects is varying a lot. While there are cases which had relatively normal lives, there are others who are totally bed-ridden and are unable to take care for themselves. The majority of the persons with CFS diagnosis are drastically reducing work, school and family activities, for long time periods. Severity and disability of the syndrome are the same in both genders (11, 12).

Many cases are suffering from disabling chronic pain. Important reduction in the level of physical activity and in the complexity of the conducted activities, were noticed. The impairment is comparable to that found in late-stage AIDS, lupus, rheumatoid arthritis, chronic obstructive pulmonary disease and end-stage renal disease (13). CFS affects the functional capacity and the well-being of an individual, more than major medical conditions such as multiple sclerosis, congestive heart failure and type II diabetes mellitus (14).

Since there are no characteristic laboratory abnormalities to diagnose chronic fatigue syndrome, the recommended tests are used to exclude other causes for typical symptoms. Conditions which must be excluded are hypothyroidism, anemia, diabetes, psychiatric disorders – major depression, anorexia nervosa, bulimia, bipolar disorder, alcohol and other substances abuse. Multiple chemical sensitivity, Gulf War syndrome and post-polio syndrome have symptoms similar to those of CFS (14).

THERAPEUTIC POSSIBILITIES

Most often, even under therapy, a full recovery from chronic fatigue syndrome is rare. Cognitive behavioral therapy, graded exercise therapy, as well as pacing have been moderately effective for many cases. These therapeutic methods are useful in monitoring and self-consciousness, in managing the symptoms and adapting the level of activity to the possibilities of the subject (15). Since the syndrome is polymorphous and shows different manifestations in different subjects, the therapy should be adapted to the needs of each individual.

Medication plays a minor role in management of the syndrome. Antidepressants and immune-modulators are used; the role of antidepressants remains controversial (16, 17).

PROGNOSIS

Evolutions with remission and relapse, which make more difficult the management of the syndrome, are frequent. In remission, the extending of the activities may easily worsen the symptoms, with relapse.

Occupational disability is important, since more than half of the cases are unable to work, while almost two-thirds of the cas-

es are limiting their work; less than a fifth of the cases are working full-time (11).

The average full recovery rate in people with chronic fatigue syndrome is of 5 % (range 0-31 %). In the conducted studies, an improvement with consequently increase of the quality of life, is reported in 39.5 % (18).

Yet, the etiology, pathophysiology, nomenclature and diagnostic criteria of the chronic fatigue syndrome are a matter of controversy among specialists (18).

ATYPICAL PRESENTATION OF SYSTEMIC LUPUS ERYTHEMATOSUS: PAROTITIS AND SECONDARY SJOGREN'S SYNDROME (A CASE REPORT) (Abstract): Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by auto antibodies directed against self-antigens, immune complex formation and immune deregulations and may affect joints, skin, kidneys, heart, lungs, nervous system, and immune system. The onset can be variable and the symptoms can occur for many years. Parotitis as the initial manifestation of systemic lupus erythematosus (SLE) is a rare condition and can be associated with Sjogren's syndrome. In this article we present the case of a young patient who was diagnosed with Sjogren's syndrome retrospectively, after she met the criteria for SLE. **Keywords**: SYSTEMIC LUPUSERYTHEMATOSUS, PAROTITIS, SJOGREN'S SYNDROME.

Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by auto antibodies directed against self-antigens, immune complex formation and immune deregulations and may affect joints, skin, kidneys, heart, lungs, nervous system, and immune system (1). The onset can be variable and the symptoms can occur for many years (2). Parotitis as the initial manifestation of systemic lupus erythematosus (SLE) (3) is a rare condition (4) and can be associated with Sjogren's syndrome (5).

The Systemic Lupus International Collaborating Clinics group revised and validated the ACR SLE classification criteria in 2012 (6). According to the revision, a person is defined as having SLE if any 4 or more of the 11 criteria are present, respectively or simultaneously, during any interval of observation. Parotitis associated with Sjogren's syndrome is a rare condition in childhood (7, 8).

Sjogren's syndrome may be a primary disorder or may be secondary to other autoimmune disorders, such as systemic lupus erythematosus (9). Thus, it is required to be excluded a number of underlying causes of that disease (most of them of infectious origin). The natural history of SLE is unpredictable (10). Two of the most common complications are lupus nephritis (11) and cerebral damage.

We present the case of a young patient

with SLE in which the initial manifestation was parotitis and Sjogren's syndrome.

CASE PRESENTATION

We report the case of a 10-year old girl who presented with bilateral parotid swelling, symmetrical, non-traumatic and non-thrombocytopenic purpura on the lower limbs, accentuated by physical effort and orthostatic position, without fever (fig.1). Her symptoms have progressed gradually over the past 12 months.

The patient's past medical history is only remarkable for parotitis diagnostic, one year ago. She also accused intermittent arthritis, ocular manifestations consisting of itching and pain, recurrent epistaxis and photosensitivity. She has no other family history of medical illnesses, particularly heart disease or connective-tissue disease.

Fig. 1. Bilateral parotid swelling

The patient's physical examination reveals a normal nutritional state (BMI=21 kg/m2), "butterfly rash", bilateral swelling parotid, gingivostomatitis, an arterial blood pressure of 105/65 mmHg, a heart rate of 72 beats per minute, a respiratory frequency of 20 per minute, symmetrical purpura on the lower limbs; clinical examination did not reveal any tenderness of the abdomen, no hepatomegaly or splenomegaly and no arthritis.

Traumatic and toxic causes have been excluded, clinically and anamnestically. Multiple bacterial and viral infectious agents have been associated with the development of parotitis. We therefore determined serologies for HIV 1 and 2, cytomegalovirus (CMV) and Epstein-Barr (EBV) viruses' infection and IgG fractions were positive for CMV and EBV. Mumps was excluded anamnestically (disease was present in her medical history) and the clinical examination did not correspond to a condition manifested by acute symptoms such fever, shivering, myalgia, pain and local skin changes. Tuberculosis was excluded by negative history for TB contact, negative tuberculin intradermal reaction (IDR) and normal chest X-ray. Other bacterial infections were excluded. Mikulicz syndrome was also ruled out by clinical appearance of the parotid glands, absence of both lacrymal and submaxillary glands'swelling and lack of other syndromes (chronic lymphocytic leukemia, sarcoidosis). Maxillofacial consultation excluded sialolithiasis and reported gingivostomatitis, tooth cavities and dry mouth (fig. 2).

Fig. 2. Gingivostomatitis

Ophtalmological examination has found xerophtalmia and dry eyes. The diagnostic of Sjogren's syndrome could not be confirmed by biopsy.

Laboratory tests showed other pathological associated issues which pleaded for an autoimmune disease: an important inflammatory syndrome (erythrocyte sedimentation rate - ESR of 131 mm per hour), C-reactive protein (CRP) was positive in all determinations, a very high value of total serum proteins (122 g/l), hypergammaglobulinemia (51.7%), mild normochromic, normocytic anemia (haemoglobin - Hb of 9 g/dL), plasmocytic expansion on bone marrow biopsy. Bence-Jones protein was not determined, but multiple myeloma is usually met in adults over 40 years. Other serologies like p-ANCA and c-ANCA antibodies were negative. Liver function tests revealed mild hepatocytolysis (ASAT 45 U/L, ALAT 63 U/L), kidney function (urea, creatinine, clearance of creatinine) was normal. The abdominal ultrasound examination revealed no pathological findings.

Our case meets 5 of the 11 required ACR criteria for SLE: "butterfly rash", arthritis, photosensitivity, immunological changes such as anti-nuclear antibody titer (ANA) over 32 (positive titer over 1), anti-deoxyribonucleic acid antibodies (dsDNA) positive titers. These findings are classical for SLE. We believe those findings to be consistent with lupus associated with Sjogren's syndrome.

We also excluded other viral infections (hepatitis B, C) and we evaluated the status of lupus-target organs (heart – the cardiac ultrasound exam was normally, kidney – function and ultrasound exam) for initiating the therapy with corticosteroids. Cortisone therapy included methylprednisolone pulses, three consecutive administrations (30 mg/kg/day), following the oral medication.

Clinical and paraclinical evolution was slowly favorable with remission of arthralgia, decreased parotid swelling, improvement of biological inflammatory syndrome (ESR decreased at 70 mm/h), anemia (Hb of 11.4 g/dl). But a number of adverse effects and complications of immunosuppression were present: over-weight (8 kg), stretch marks, a prolonged evolution of gingivostomatitis, despite local treatment and oral hygiene, which could lead to a series of infectious complications such maxillary sinusitis, chronic rhinitis, conjunctivitis and urinary infections. She had no pancreatic involvement during evolution, the pancreatic ultrasound and levels of pancreatic enzymes were normal.

After two years of evolution the patient showed renal impairment: persistent hematuria and proteinuria, low levels of C'3 fraction of complement. It required renal biopsy for staging of lupus nephritis and so she was transferred to the Nephrology Clinic.

DISCUSSION

Primary Sjogren's syndrome occurs in the absence of another underlying rheumatic or immune disorder, while secondary Sjogren's can be associated with other diseases, such as systemic lupus erythematosus (SLE), scleroderma, rheumatoid arthritis (RA).

Thus, there is an overlap of Sjogren's syndrome with many other immune mediated diseases and it is sometimes difficult to determine whether a clinical manifestation is a primary consequence of Sjogren's syndrome or is due to one of its overlapping disorders.

Almost half of patients with Sjogren's syndrome also present with cutaneous find-

ings, such as dry skin (xeroderma), palpable and nonpalpable purpura, and/or urticaria (12).

Primary disease is a rare condition in childhood; only 145 cases of primary disease have been described in the international pediatric literature (13, 14). The majority of patients with Sjogren's are in conjunction with other autoimmune diseases, which are considered secondary to Sjogren's syndrome.

Individuals with secondary Sjogren's syndrome may have systemic lupus erythematosus, scleroderma, and primary biliary cirrhosis; therefore it takes a whole battery of tests and investigations for these patients to exclude other disorders.

Also, long-term, Sjogren's syndrome can lead to complications that affect teeth, kidneys, eyes, lungs and joints and even to lymphoma (15). Another rare manifestation in lupus is cerebral vasculitis.

In the literature there have been documented only few cases of atypical onset of Sjogren's syndrome (16).

In two of these cases the age of diagnosis was 10 years, similar to the age of our case.

In our experience and evidence with 40 cases of systemic lupus erythematosus this is the only case with associated Sjogren's syndrome.

AMNIOTIC MEMBRANE AND FINGERTIP INJURIES

A group of researchers from Department of Orthopaedic Surgery, Shiraz University of Medical Sciences conducted a study that evaluated the efficacy of amniotic membranes (AM) as a biologic wound dressing material for coverage of fingertip injuries, which are the most common hand injury, represent management challenges for hand surgeons. The study included 30 patients with full-thickness zone 1 fingertip skin loss. The patients were divided into 2 groups using the block randomisation method. In the first group, a skin graft was used for coverage and in the second group, AM was used. All patients were operated on by the same hand surgeon between February 2012 to October 2012. The minimum follow-up period was 6 months. Two point discrimination (T.P.D), light touch, healing time, days lost from work and infection rate were evaluated and recorded. Fingertips in both groups were assessed. T.P.D, light touch and days lost from work were significantly lower in the AM group than in the skin graft group. Healing time was lower in the skin graft group. In the both groups, no infection was detected. Patients of both groups were satisfied of their treatment and healing progress. The authors showed the effectiveness and safety of AM for the treatment of fingertip amputation, which can produce better sensation and functional outcomes than skin graft transplantations. BIPOLAR DISORDER, NOT SO RARE DIAGNOSIS: SUBTYPES OF DIFFERENT DEGREES OF SEVERITY, DIAGNOSIS, THERAPY

Ioana Cristina Amihăesei
University of Medicine and Pharmacy "Grigore T. Popa" – Iaşi
Faculty of Medicine
Discipline of Histology

BIPOLAR DISORDER, NOT SO RARE DIAGNOSIS: SUBTYPES OF DIFFERENT DEGREES OF SEVERITY, DIAGNOSIS, THERAPY (Abstract): Bipolar disorder is manifesting as a mood disorder, typically showing episodes of mania, alternating with depressive episodes. The subtypes are including bipolar I disorder (one or several manic episodes) and bipolar II disorder (hypomanic episodes and one or several major depressive episodes). Nevertheless, sub-threshold diagnosis criteria may include another 5.1, up to 6.4 % of the population as having a bipolar spectrum disorder diagnosis. Anyone who received the diagnosis is not considered cured afterwards (just in remission). Diagnosis is considering the symptoms of mania, hypomania and depression. Therapy is based on lithium, anticonvulsants, for the manic symptoms, lamotrigine for the depressive episodes and antipsychotics. Under medication, most of the affected subjects are living a normal life; to a certain degree, medication may also prevent the relapses. **Keywords:** BIPOLAR DISORDER, MANIA, HYPOMANIA, MAJOR DEPRESSIVE EPISODES.

Bipolar disorder is considered a mental illness manifested as a mood disorder, also known as bipolar affective disorder, manic-depressive disorder, or manic depression. Typically, subjects with bipolar disorder show episodes of mania alternating with periods of depression. Approximately 4 % of the general population is affected by bipolar disorder. Prevalence is the same in men and in women and in different cultures and ethnic groups.

Variations in moods and energetic level were observed as part of the human personality, since ancient times. Terms like melancholia and mania have origins in Ancient Greek language. At the beginning of the 19th century, a French psychiatrist Jean-Etienne Dominique Esquirol described lypemania, an affective monomania and became the first to contour the modern depression (1).

In 1854 Jules Baillarger detailed to the French Imperial Academy of Medicine a biphasic mental illness, manifested with periodic mood changes between mania and depression; he used the term of "dual-form insanity", named afterwards by Jean-Pierre Fairet "circular insanity"(2). The concept was further developed by the German psychiatrist Emil Kraepelin, who used the concept of cyclothymia and he studied the evolution of the untreated bipolar cases. Adolf Meyer introduced the concept of bipolar disorder, as a result of genetic factors influenced by social and psychological factors.

In 1957, the German Psychiatrist Karl Leonhard was the first to define the subtypes of bipolar disorder, he also introduced the concept of bipolar and unipolar, to characterize the forms with exclusively depressive episodes.

EPIDEMIOLOGY

Approximately 4 % of the population has one of the bipolar disorder types at a certain period in their life. Further analysis of data from the USA is showing that 0.8 % of the population experience at least an unique manic episode (the diagnosis criterion for bipolar I) and 0.5 % have a hypomanic episode (the diagnosis criterion for bipolar II or cyclothymia).

When sub-threshold diagnostic criteria were included (such as one or two symptoms over a short time-period), another 5.1 % up to 6.4 % were considered as having a bipolar spectrum disorder (3). A recent analysis of data from US National Comorbidity Survey showed that 1 % of the population had lifetime prevalence criteria for bipolar I, 1.1 % for bipolar II and 2.4 % for sub-threshold symptoms. Data are similar in both sexes and in different cultures and ethnic groups. However, the severity of the disease may vary widely across the globe. Late adolescence and early adulthood are peak years for the onset of bipolar disorder (4).

Bipolar disorder can cause suicidal ideation that leads to suicidal attempts. One out of three patients with bipolar disorder reports past attempts of suicide, or succeeds it. The annual average suicide rate is 0.4 %, 10 to 20 times higher than in the general population. The standardized mortality ratio from suicide in bipolar disorder is reported to be between 18 and 25 (5).

SUBTYPES

There is no clear consensus in what concerns how many types of bipolar disorder do exist. The concept of bipolar disorder is referring to a spectrum of disorders; the newest classification includes three specific subtypes and a non-specified form.

Bipolar I disorder is characterized by one or several manic episodes. Further is registered if there were several episodes and the type of the most recent episode. A depressive or hypomanic episode is not required for diagnosis, but it often occurs.

Bipolar II disorder is characterized by the missing of the manic episodes; instead are appearing one or several hypomanic episodes and one or more major depressive episodes. Hypomanic episodes do not show as severe manifestations as mania does, and usually do not impair drastically social and/or professional life and do not manifest psychotic symptoms. This can make bipolar II disorder harder to diagnose; hypomanic episodes may look like periods of successful achievements, being less reported, unlike distressful depressive episodes.

Cyclothymia is described like a history of hypomanic episodes, alternating with episodes of depression, which do not meet diagnosis criteria for major depressive episodes. A low degree of mood cycling does exist, which is observed as a personality trait and is interfering with functioning of the individual.

Bipolar disorder NOS (not otherwise specified) is the diagnosis established when the disorder is not meeting the criteria for a specific subtype (6).

DIAGNOSIS

Signs and symptoms of bipolar disorder include abnormally elevated (manic or hypomanic) mood estates which impair

normal functions of daily life. Numerous cases experience also depressive episodes, although not all. A test suitable for the diagnosis does not exist, and the diagnosis may be difficult to establish, even for the psychiatric specialists. It is also hard to differentiate the depression found in the bipolar disorder, from the pure unipolar depression. An earlier age of onset is often predicting depression as the first few episodes. Since bipolar diagnosis needs a manic or hypomanic episode, many bipolar patients are first diagnosed and treated as having major depression (7).

Mania is the characteristic feature of the bipolar disorder, being a period of elevated or irritable mood, which can take the form of euphoria and is lasting at least one week. Patients usually have an increase in energy and a decreased need for sleep (most of them need just three or four hours of sleep per night). Some can go days without sleeping. Usual symptoms are pressured speech with the feeling of racing thoughts. Attention is affected, and the individual is easily distracted. Rational capacities may be impaired and the subjects may be engaged in risky behaviors, which otherwise are not characteristic for them. They may experience alcohol, cocaine or other stimulants, or sleeping pills abuse. The behavior may be aggressive, intolerant or intrusive. They may feel unstoppable, or ”chosen” and „in a special mission”, or may have another delusional ideas. Hyper sexuality may appear. At extreme, a manic estate can manifest psychosis, a break with reality, the process of thinking being affected together with the mood; sometimes this may lead to violent behaviors. Manic states may induce severe anxiety and irritability, or euphoria and grandiose ideas. Specific rating scales can measure the severity of the manic symptoms. Sleep disturbances, psychomotor and appetite changes may announce the onset of a manic episode, two or three weeks before (8).

Hypomania is a mild to moderate state of elevated mood, manifested by optimism, pressure of speech and activity and a reduced need for sleep. Unlike mania, most of the times hypomania does not interfere with normal functioning of the subject. People with hypomania are usually more productive, while manic subjects show attention troubles, which are impairing daily activities. Hypomanic subjects do not have delusions or hallucinations. Because it generally generates a state of well-being, hypomania is rarely reported as a pathologic condition. Only when depression is accompanying it, or if the mood changes are uncontrollable, hypomania may lead to search for specialized assistance. Untreated, a hypomanic episode may last from a few days to several weeks. Usually, symptoms may last a few weeks, up to a few months (9).

The depressive phase of bipolar disorder appears as persistent feeling of sadness, anxiety, guilt, anger, isolation or hopelessness. Disturbances of sleep and appetite are common, as well as: fatigue and lack of interest for enjoyable activities, decrease of concentration capacity, apathy, depersonalization, loss of interest in sexual activity, social anxiety, irritability, lack of motivation and morbid, suicidal thoughts. In severe cases psychosis may appear, known as severe bipolar depression with psychotic features. Psychotic symptoms are represented by usually unpleasant delusions or more rare, hallucinations. A severe depressive episode may last from two weeks, up to more than six months, if untreated (10).

Mixed affective episode is a condition in which symptoms of mania and depression occur simultaneously. Classical examples are weeping during mania and racing

thoughts during a depression phase. Mixed episodes are the most dangerous of the bipolar phases, since during this; the risk of suicide attempts greatly increases (5).

The later diagnosis of bipolar disorder may be preceded by different pathologic conditions developed during childhood, such as mood abnormalities, major depressive condition and ADHD (attention deficit hyperactivity disorder) (11).

Bipolar disorder should be differentiated from other mental disorders which do manifest similar symptoms, like schizophrenia, attention deficit hyperactivity disorder (ADHD) and borderline personality (12).

Bipolar disorder diagnosis is officially defined such that anyone who has a history of hypomania and depression receives this diagnosis, whatever their functioning and vulnerability are. This is considered „an ethical and methodological issue", as long as no one is considered as being recovered from bipolar disorder, only in remission, according to official criteria. This situation is delicate, since brief hypomanic episodes are widespread in population and not associated with any dysfunction (13).

THERAPY

Several medications are used in the treatment of bipolar disorder. Lithium is effective in the therapy of acute manic episodes and in preventing manic relapses; it is also decreasing the risk of suicide and self-harm in bipolar disorder (14).

Sodium valproate, which was initially used as anticonvulsant, is now an usually prescribed drug, effective in treating manic episodes (15).

Lamotrigine is to a certain degree, effective in the treatment of the bipolar depression (16). According to the severity of the disease, anticonvulsants can be used in combination with lithium, or alone.

Antipsychotics are used in the therapy of mania, although the long term effects are not clear. Olanzapine is used for prevention of relapses, even if it is not as effective as lithium.

Antidepressants showed no higher efficacy than that of the mood stabilizers. Benzodiazepines are used as adjuvants to medications.

Psychotherapy is targeting the alleviation of main symptoms, recognition of relapse risk and maintenance of remission. Psycho education and cognitive behavioral therapy are efficient in preventing relapses (17).

RECOVERY AND RECURRENCE

Studies showed that 50 % of hospitalized (which means most severe cases) had full recovery in six weeks, and 98 % in two years. In two years, 72 % had symptomatic recovery (lack of all symptoms) and 43 % functional recovery (prior occupational and living status). Nevertheless, 40 % experienced a new episode within two years of syndrome recovery and 19 % evolved without recovery (18).

ORAL APIXABAN FOR THE TREATMENT OF ACUTE VENOUS THROMBOEMBOLISM

Apixaban, an orally administered factor Xa inhibitor, may be, according to a recent study, an alternative to the standard treatment of venous thromboembolism. In this study, double-blind, randomized, was compared apixaban (at a dose of 10 mg x 2/day 7 days followed by 5 mg x 2/day 6 months) with conventional therapy (subcutaneous enoxaparin followed by warfarin) in 5395 patients diagnosed with acute venous thromboembolism. Apixaban proved noninferior to conventional therapy ($p < 0.001$). Major bleeding occurred in 0.6% of patients receiving apixaban and 1.8% of those who received conventional treatment. Rates of other adverse effects were similar in the 2 groups. The results of next studies will provide data on the safety and efficiency of administration to selected groups of underweight patients with cancer or with a creatinine clearance below 50ml/min. (Agnelli G, Buller HR, Cohen A, et al., Oral Apixaban for the treatment of acute venous thromboembolism, *N Engl J Med* 2013; 369: 799-808)

CURRENT STATUS IN VITAMIN D AND REGULATORY T CELLS (IMMUNOLOGICAL IMPLICATIONS) (Abstract): There has been a continuous effort to understand possible non-Ca metabolism roles of vitamin D, including its role in the immune system and, in particular, in T cell-medicated immunity. Vitamin D receptor is found in significant concentrations in the T lymphocyte and macrophage populations, when we refer to immune system, and pretty much in any human tissue and cells. Until the eighties, *no one* had imagined that vitamin D might play a role in the functioning of the immune system. Today we accepted that the normal immune system harbors a regulatory T cell (Treg) population specialized for immune suppression. Currently, the most commonly known regulatory T-cell lineage is called $CD4^{+}CD25^{high}FoxP3^{+}$ regulatory T cells. Several autoimmune disorders have been linked to a deficiency in vitamin D_3. In some autoimmune diseases, including multiple sclerosis (MS), a compromised Treg function is believed to be critically involved in the disease process. Vitamin D insufficiency has ramifications not only for bone health, but also in other non-skeletal areas of vitamin D function, such as immune cells, muscle cells and, perhaps, adipocytes. As a final conclusion, further researches in the field of vitamin D, Tregs, immunity (inflammatory processes, rejection, autoimmune diseases, etc.), either *in vitro* on cell cultures or *in vivo* using lab animals or volunteers are still necessary. **Keywords:** VITAMIN D, REGULATORY T CELLS (TREG), AUTOIMMUNE DISEASES, VITAMIN D RECEPTOR (VDR), FORK-HEAD BOX P3 (FOXP3), ADIPOGENESIS, ADIPOCYTE

In recent years there has been an effort to understand possible non-Ca metabolism roles of vitamin D, including its role in the immune system and, in particular, on T cell-medicated immunity. Vitamin D receptor is found in significant concentrations in the T lymphocyte and macrophage populations, when we refer to immune system, and pretty much in any human tissue and cells. However, its highest concentration is in the immature immune cells of the thymus and the mature CD8 T lymphocytes. Until 1980, *no one* had imagined that vitamin D might play a role in the functioning of the immune system. The function of vitamin D was largely considered to be in the area of calcium, phosphorus, and bone metabolism. It prevents rickets in children,

osteomalacia in adults, and hypocalcemic tetany. Continued pursuit of the metabolism of vitamin D resulted in the understanding that vitamin D must first be hydroxylated in the liver to form 25-hydroxyvitamin D_3 ($25(OH)D_3$), the major circulating form of the vitamin (1). This form of vitamin D was subsequently found to be metabolically inactive and must be further converted to a final active form, 1□,25-dihydroxyvitamin D_3 ($1,25(OH)_2D_3$) (2, 3). The attempt to understand how the active form of vitamin D carries out its functions led to the discovery of vitamin D receptor (VDR) in 1974 and 1975 (4, 5). It became clear that this $1,25(OH)_2D_3$ (radiolabelled) is localized almost entirely in the nucleus in a specific fashion in target tissues. This localization was also found in other tissues not previously considered targets (6, 7). For example, keratinocytes of skin, islet cells of the pancreas, lymphocytes, and promyelocytes, adipocytes, etc. showed specific nuclear localization of $1,25(OH)_2D_3$ and the presence of VDR. The discovery of VDR in these tissues resulted in the idea that vitamin D hormone had functions beyond calcium and phosphorus metabolism, which prompted investigations into the noncalcemic actions of vitamin D (8). Noting VDR in promyelocytes, Abe et al. and Tanaka et al. (9, 10). demonstrated that vitamin D hormone can suppress proliferation of promyelocytes and cause their differentiation into the monocyte. Similar effects of vitamin D hormone on several cancerous cell lines ensued (11). A role of vitamin D hormone in cellular differentiation thus became known.

It is now widely accepted that the normal immune system harbors a regulatory T cell (Treg) population specialized for immune suppression (12). Tregs exert functions in the induction and maintenance of immune tolerance (13-16). The family of Tregs is represented by a heterogeneous cell population that includes adaptive and naturally occurring Tregs (13-16). According to the current paradigm, adaptive Tregs develop from naïve T cells in the periphery and can produce IL-10 and transforming growth factor β (TGF β), whereas naturally occurring Tregs originate in the thymus as $CD4^+CD25^+$ cells and perform their suppressive functions through cell-to-cell contacts and membrane-bound TGF β and cytotoxic T-lymphocyte antigen-4 (CTLA-4) (13-16). The transcription factor FoxP3 is necessary for the development of this subpopulation of $CD25^+$ Tregs, being their characteristic marker (17).

Vitamin D and Tregs interactions and possible pathways

Broadly speaking, Tregs have the capability to suppress the activity of the immune system and to regulate self-tolerance. However, it is not possible to unambiguously define Tregs as a homogeneous group, since T cells of different phenotypes have been shown to exhibit immune regulating potential (18). Currently, the most commonly known regulatory T-cell lineage is called $CD4^+CD25^{high}FoxP3^+$ regulatory T cells. The fork-head box p3 (FoxP3) transcription factor is the cell lineage–determining master transcription factor of this T-cell subtype (18). Generation of Tregs is shown to depend on the cytokine transforming growth factor (TGF)-β (19). A new population of Tregs has been described lately that is under the regulation of interleukin IL-35 (TR_{35}) (18). Although the first report showed them to be $FoxP3^+$, a more recent study suggests that T_{R35} cells

are independent of FoxP3 (20). Because not much information exists regarding the influences of dietary products on generation or function of this population, within this report, Tregs are defined as $CD4^+CD25^+$ $FoxP3^+$ T cells unless otherwise stated (18).

Vitamin D_3 can be generated in the skin through processes using ultraviolet B (UVB)-mediated photolysis of a cholesterol derivative and a spontaneous isomerization step. Vitamin D_3 needs to be enzymatically active to its hormonal form! Because endogenous production of Vitamin D depends on UVB exposure, the concentration is highly influenced by environmental factors such as seasonal sunshine length and latitude, behavioral factors such as time and surface area of exposed skin, skin pigmentation and age.

Vitamin D_3 is also taken up through diet. These factors lead to great variations in its circulating form and calcidiol, spurring an ongoing discussion about "natural," "normal" and "desired" levels of Vitamin D and its derivatives. A daily intake of 100 µg (4,000 IU) is suggested as a safe dose, elevating the $25(OH)D_3$ levels to desired concentrations in most humans (21). This number is higher than the recommended nutrient intake of between 5 and 15 µg/day (200–600 IU) by WHO (World Health Organization).

This section deals with the role of Vitamin D and its derivatives on the immune system, focusing on their effects on $FoxP3^+$ Treg generation and function in different diseases. UVB light exposure as well as local calcipotriol (a synthetic derivative of calcitriol) treatment can lead to vitamin D receptor (VDR)-dependent induction of $FoxP3^+$ Tregs in the skin (18). Vitamin D_3 supplementation is reported to reduce the CNS autoimmune disease EAE (experimental autoimmune encephalomyelitis) in females but not in males or ovariectomized female mice. The disease protection correlated with high local $1,25(OH)_2D_3$ (active form) levels in the inflamed spinal cord, but not in serum. It was suggested a slower degradation of $1,25(OH)_2D_3$ process in the CNS, mediated through a suppression of the enzyme CYP24A1, a 24-hydroxylase with $1,25(OH)_2D_3$–inactivating properties (18, 22, 23). The protective effect in females could be restored in ovariectomized females through estrogen supplementation (24).

An additional pathway for the treatment effect of $1,25(OH)_2D_3$ has been shown by induction of high numbers of $FoxP3^+$ Tregs in combination with IL-2 (25). In support of this, dietary administration of 1α-(OH)-vitamin D_3, an active vitamin D_3 analog, led to reduced diabetes in non-obese diabetic mice and increased $FoxP3^+$ T cells (26). Previously, it was shown that a $1,25(OH)_2D_3$ analog also had a therapeutic effect in a spontaneous autoimmune non-obese diabetic model, resulting in an increased protective $CD25^+$ Treg population (28).

A combination of $1,25(OH)_2D_3$ and the anti-inflammatory corticosteroid dexamethasone synergistically induced primarily IL-10–producing $FoxP3^-$ Tregs (28, 29). Anyway, in an experimental IBD (inflammatory bowel disease) model, $1,25(OH)_2D_3$ and dexamethasone had a FoxP3 expression–promoting effect in the gut (30). Not only was the amount of FoxP3 expression increased by $1,25(OH)_2D_3$ treatment, but the potency of $FoxP3^+$ Tregs was accentuated, even in a Th2-driven *in vivo* asthma model (31).

The $1,25(OH)_2D_3$ precursor calcidiol

[25(OH)D_3] is mainly 1α-hydroxylated in the kidney to its active form, but also it has been shown to be processed in immune cells (18). $CD3^-$ and $CD28^-$ activated T cells as well as dendritic cells (DCs) are able to produce 1,25$(OH)_2D_3$ from its precursor, but T cells could not directly produce precursor from Vitamin D under these conditions (18). To support this, it is shown that 1α-hydroxylase is highly up-regulated in activated human T cells (32). Furthermore, 1,25$(OH)_2D_3$ up regulates VDR expression, which has been shown to correlate with the protective effects of 1,25$(OH)_2D_3$ in EAE (18). Nevertheless, it is reported that 1,25$(OH)_2D_3$ induces $FoxP3^+$ Treg conversion. Was also showed that multiple sclerosis (MS) patients have lower levels of calcidiol and 1,25$(OH)_2D_3$ during active disease, suggesting that Vitamin D_3 metabolites might play a role in controlling Treg formation and the inflammatory process. This role is further underlined by findings about positive correlations of serum calcidiol and Treg function in MS patients (32, 33). Upper studies also received support in a retrospective analysis of serum samples preceding disease onset and from epidemiological studies showing an inverted correlation of sun exposure and MS prevalence (34). Although CNS-specific conversion of encephalitogenic T cells into $FoxP3^+$–induced Tregs is described (18), its correlation to local vitamin D levels is still obscure. The instability of pancreas-retrieved Tregs has been suggested (35), but it is not reported if this is correlated to levels of vitamin D derivatives in pancreas of diabetic mice. Studying the endogenous levels of vitamin D derivatives in other target tissues of immune attacks, such as in gut, joint and lung, and their role in induction of tissue-induced Tregs could be valuable.

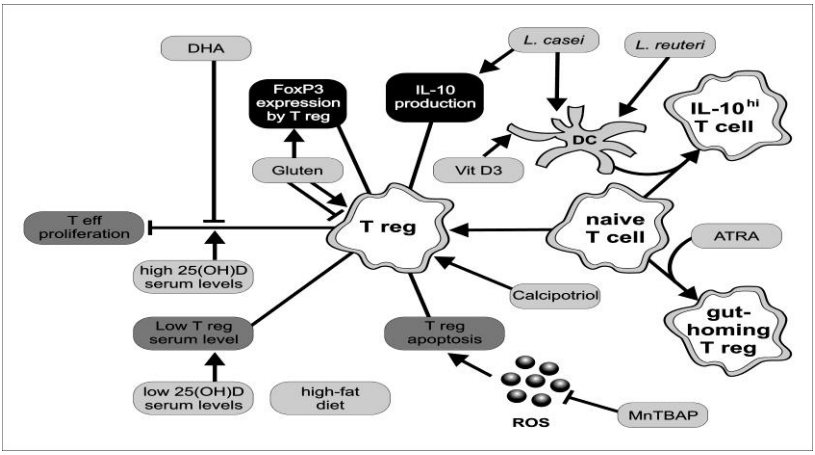

Fig. 1. Overview of dietary components and conditions (represented by dark grey boxes) influencing regulatory T cells (Tregs). The Treg-modulating effects of dietary components could be direct by mediating expansion and/or suppressive function of Tregs or indirect via modulation of DCs and their subsequent actions on Tregs. Additionally, the indirect influence of dietary components could be mediated by regulation of naive T cells to convert to Tregs or by blocking the function of inflammatory effectory T cells (Teffs). The positive anti-inflammatory effects of Tregs are mediated by expression of FoxP3 and production of IL-10 (indicated by black boxes). ROS = reactive oxygen species. $IL\text{-}10^{hi}$ = high expression of IL-10. (18 modified)

Vitamin D + Treg cells in autoimmune diseases

Several autoimmune disorders have been linked to a deficiency in vitamin D_3 (17, 36).

In some autoimmune diseases, including multiple sclerosis (MS), a compromised Treg function is believed to be critically involved in the disease process. In vitro, the biologically active metabolite of vitamin D has been shown to promote Treg development. A poor vitamin D status has been linked with MS incidence and MS disease activity (33). Moreover, high circulating levels of vitamin D have been associated with lower risk of multiple sclerosis (32).

Vitamin D is an important regulator of the immune system in general and multiple sclerosis in particular. Experimentally, invariant natural killer T (iNKT) cells have been shown to be important suppressors of autoimmune diseases such as experimental autoimmune encephalomyelitis (EAE; an animal model of MS), as shown in literature. On the other hand, in experimental allergic asthma iNKT cells are required for disease induction and are therefore pathogenic. The active form of vitamin D (calcitriol) suppresses EAE. The development of EAE symptoms is accelerated in vitamin D deficiency. Interestingly experimental asthma is less severe in vitamin D deficiency although there is no effect of calcitriol on disease severity. The data suggest that an important target of vitamin D in EAE and asthma are the iNKT cells. Vitamin D and/or vitamin D receptor deficiency results in the impaired development of iNKT cells. Vitamin D is critical very early during development of the immune system. Low levels of vitamin D *in utero* resulted in significantly reduced numbers of iNKT cells that failed to recover when calcitriol was used to supplement neonatal or adult mice. The data suggest that one of the consequences of early vitamin D deficiency is a reduction in the numbers of iNKT cells that develop. The iNKT cells are required for the beneficial effects of calcitriol in EAE. The important role of vitamin D on iNKT cells could impact the development of human immune-mediated diseases including MS and asthma (37).

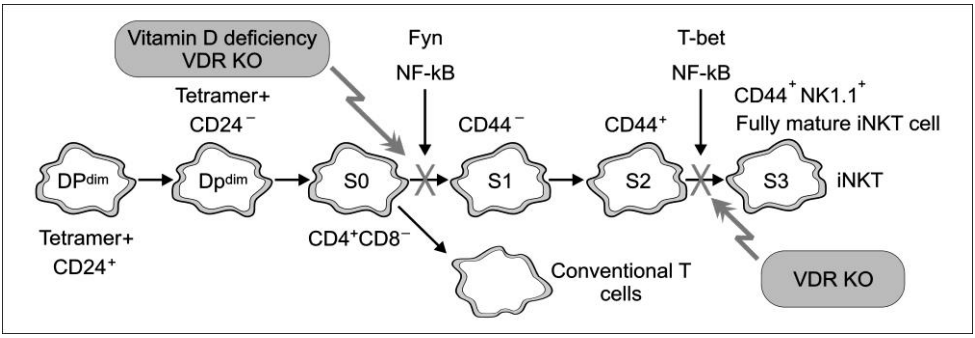

Fig. 2. Vitamin D and vitamin D receptor (VDR) targets in invariant natural killer T (iNKT) cell development (38, 39 modified).

iNKT cells develop in the thymus following several different phenotypic changes. The earliest iNKT cell precursor, DPdim expresses the invariant T-cell receptor (tetramer +) and $CD24^+$. The early iNKT cells down-regulate CD24 and diverge from the

other CD4/CD8 DP cells that go on to become conventional T-cells. Expression of two transcription factors (Fyn and NF-kB) is important in the movement of iNKT cells from stage (S) 0 to S1. Vitamin D and VDR deficiency affect the number of iNKT cells that rapidly expand and enter the S1 stage in maturation. There is no effect of vitamin D deficiency on the further maturation of iNKT cells. VDR knockout (KO) iNKT cells have an additional block in maturation at the S2 stage and fail to fully develop into mature iNKT cells. T-bet and NF-kB expression is associated with the transition of iNKT cells from S2 to S3. VDR KO iNKT cells express significantly less T-bet than there fully mature S3 wild-type counterparts (see Fig. 2) (37, 39).

Vitamin D3 is known to induce Treg cells by rendering antigen-presenting cells with immunologic tolerance (tolerogenic), its direct effect on human naturally occurring Treg cells is unclear. Some groups investigated if and how $1,25(OH)_2D_3$ can directly affect the proliferation and function of human naturally occurring Treg cells *in vitro*. So they demonstrated that these Treg cells express vitamin D receptors that were up-regulated following anti-CD3/CD28-bead stimulation. $1,25(OH)_2D_3$ inhibited proliferation of Treg cells even when exogenous interleukin-2 was provided. Treg cells were more susceptible to the inhibitory effect of $1,25(OH)_2D_3$ than conventional T cells. $1,25(OH)_2D_3$ neither affected the anergic state nor the suppressive function of Treg cells but induced a subtle increase in interleukin-10-secreting cells. The cell-division-inhibiting effect of $1,25(OH)_2D_3$ on Treg cells was also demonstrated *in vivo* by supplementing vitamin D-deficient HIV-1-infected patients with 2000 IU cholecalciferol (vitamin D_3), conform with literature. Increased serum $1,25(OH)_2D_3$ levels were associated with a drop in the number and percentage of Treg cells, which may be attributed to a decrease in the proliferating $FoxP3^+$ Treg cell population (40).

Treg cells are characterized by a $CD25^{high}$ $CD4^+$ phenotype and signature transcription factor, fork-head box protein 3 (FoxP3). They are a part of the immune system and are crucial in the regulation of immune homeostasis (40). It has been demonstrated that the regulatory function of $CD4^+$ $CD25^+$ Treg cells is hindered in autoimmunity, allergy and infectious diseases, indicating that these cells play a huge role in immune-mediated pathology. In last years, evidence has conducted researchers to the potential therapeutic application of Treg cells either in potentate their regulatory activity in inflammatory diseases such as autoimmunity, allograft rejection, graft versus allergic diseases and/or host disease also in blocking their suppressive activity related to tumor immunity or vaccine development (40).

VITAMIN D AND ADIPOGENESIS

Despite the ability to synthesize vitamin D in the skin and the availability of vitamin D in some foods, vitamin D deficiency is increasingly recognized as a widespread global nutritional problem, as shown in literature (41). Vitamin D insufficiency has ramifications not only for bone health, but also in other non-skeletal areas of vitamin D function, such as immune cells, (42) muscle cells and, perhaps, adipocytes (43, 44).

Studies conducted in Japan almost 20 years ago indicated that treatment of 3T3-L1 pre-adipocytes in culture with $1,25(OH)_2D_3$, the bioactive form of vitamin D, affected differentiation and adipocyte metabolism. (47). These early studies indi-

cated that nM concentrations of 1,25-$(OH)_2$-vitamin D could inhibit adipogenesis and reduce the accumulation of triacylglycerol by 50% compared to fully differentiated control cells. In addition, treatment of pre-adipocytes with other vitamin D metabolites, such as 24,25-$(OH)_2$-vitamin D, could also inhibit pre-adipocyte differentiation, but at higher concentrations than $1,25(OH)_2D_3$ that paralleled their reduced affinity for the vitamin D receptor. These early studies also noted that specific $1,25(OH)_2D_3$ binding was evident in pre-adipocyte 3T3-L1 cells, but there was no evidence of specific binding for $1,25(OH)_2D_3$ in mature adipocytes (42). This finding is consistent with the idea that any influence of vitamin D on adipogenesis would likely be exerted early in the pre-adipocyte to adipocyte transition when more VDR was available. Theoretically, the sensitivity of the pre-adipocyte to $1,25(OH)_2D_3$ would be increased by a greater amount of vitamin D receptor or other limiting VDR-associated proteins. More than a decade ago, it was shown that one of the early effects of $1,25(OH)_2D_3$ treatment of 3T3-L1 pre-adipocytes was an increase in vitamin D receptor mRNA expression in pre-adipocytes, which occurs within 4h of treatment in cell culture (42). Little was appreciated, however, about any direct importance of the unliganded VDR in adipogenesis, or the molecular details whereby $1,25(OH)_2D_3$ treatment inhibited differentiation of pre-adipocytes.

DISCUSSION

Summarizing all written up, we could say that definitely exist profound metabolic links via multiple metabolic and signaling pathways between vitamin D (provided as food intake or endogenous produced), its active hormonal form $1,25(OH)_2D_3$, VDR from various cells (bone, muscle, hepatocytes, epithelial cells, neurons, white cells, adipocytes), various other signaling proteins (cytoplasmic and nuclear) or enzymes, transcriptional and translational factors in nuclei, and various genes (vitamin D direct related or others).

So, various groups studied different aspects of vitamin D intake amount, in those various levels in its pathway (metabolically, signaling, etc.) and its effect over immunity (hence its relation with Tregs), beyond vitamin D effects on calcium metabolism. Various groups oriented their research over vitamin D and adipogenesis and inflammation related to adipose tissue. Numerous groups studied interrelations between vitamin D and Tregs in many autoimmune diseases, infections, allergies, organ rejection and so on.

Starting from all this work done or still in progress, we could summarize it is still necessary to study on *in vitro* and *in vivo* (on lab animals and voluntary patients) the non-calcemic effects in metabolism by vitamin D (and her derivatives) in an healthy organism or in many diseases, to either ameliorate there, the effects of that disease (or medication related disease) or as co-treatment even.

CONCLUSIONS

The work in the field of vitamin D, Tregs, immunity (inflammatory processes, rejection, autoimmune diseases, etc.) is still necessary either *in vitro* on cell cultures or *in vivo*, using lab animals or volunteers. Also, studies on the relation between vitamin D, Tregs and adipocytes are still needed, this avenue requiring a huge amount of work, to which our research group is hoping to contribute in the future.

CORRELATION GENOTYPE – PHENOTYPE IN TRISOMY X: A RETROSPECTIVE STUDY OF A SELECTED GROUP OF 36 PATIENTS AND REVIEW OF LITERATURE (Abstract): Trisomy X (47,XXX) is a gonosomal aneuploidy characterized by the presence of an extra X chromosome in a female person. Usually the diagnosis is established made postnatally by chromosome analysis in patients with suggestive clinical signs. Clinical signs vary by age. In prepubertal patients have a growth retardation associated with uncharacteristic facial dysmorphism, mild mental retardation with behavioral disorders**,** plus clinical signs of ovarian dysgenesis**,** postpubertal. **Aim:** We analyzed retrospectively the genotype - phenotype correlations for a selected group of 36 patients diagnosed with trisomy X (homogeneous or mosaic) by cytogenetic methods (X chromatin and karyotype). **Material and methods:** Analysis of the clinical data of 36 patients diagnosed with trisomy X and correlation with the results of X chromatin and karyotype. **Results**: Clinical signs detected in patients with homogeneous trisomy X 47,XXX (22.22%), mosaic 46,XX/47,XXX (16.66%) or 47,XXX/48,XXXX (5.55%) were prepubertal, growth retardation associated with dysmorphic facial (upslanted palpebral fissure, epichantus, thin lips) and postpubertal, signs of ovarian dysgenesis (secondary amenorrhea, early menopause). The phenotype of patients with different gonosomal mosaic corresponding to Turner syndrome, incorporating a cell line with trisomy X (55.55%) was variable, correlated with the type of chromosomal abnormalities detected. **Conclusions**: The results of our study are similar to those obtained in other studies and emphasizes that phenotypic variability of patients with trisomy X feature makes it difficult to genotype - phenotype correlations. **Keywords**: HOMOGENOUS AND MOSAIC TRISOMY X, X CHROMATIN, KARYOTYPE.

Trisomy X, which determines the triple X syndrome is an gonosomal aneuploidy characterized by the presence of an extra X chromosome in a female (1). This syndrome has a frequency of approximately 1/1000 female births, but only 10% of cases are diagnosed. In 90% of cases, the extra X chromosome results from a maternal nondisjunction in meiosis I, associated with increased maternal age at conception (1-3).

Prenatal diagnosis can be achieved through amniocentesis or chorionic villi biopsy. Postnatal diagnosis is achieved by chromosomal analysis of peripheral blood in patients presenting a suggestive clinical picture, variable by age. Prepubertal pa-

tients have hypotonia, delayed development (motor / language), uncharacteristic facial dysmorphism (upslanted palpebral fissure, round facies, hypertelorism, epicantus, ear anomalies), IQ at the lower limit of normal, cognitive impairment or behaviour, anxiety, and scoliosis. Postpubertal patients display the characteristic signs of gonadal dysgenesis: menstrual disorders (early menarche, irregular periods, early menopause) or reproductive disorders (infertility or repeated miscarriages) (1,2, 4-10).

Cytogenetic tests - sex chromatin test (Barr test) and chromosomal analysis (karyotype) – confirm the diagnosis of trisomy X.

The X chromatin test is positive, and evidence cells with one or two Barr bodies (11-13), the results being correlate with the karyotype. The most common chromosomal abnormality is free homogeneous trisomy 47,XXX, but in 10% of cases abnormalities are identified in mosaic 46,XX/47,XXX, 47,XXX/48,XXXX, 45,X/47,XXX or 45,X/46,XX/47,XXX (4,5).

The differential diagnosis is made with the other polysomy X, which may have clinical signs common with trisomy X but dysmorphic changes are more severe and patients have hypostature, severely affected intellect and sterility associated with disorders of sexual differentiation (1,13).

The presence of premature ovarian failure and developmental and behavioral disorders, requires differential diagnosis with fragile X syndrome and tall stature requires differential diagnosis with Marfan syndrome (1,13).

Prenatal detection of trisomy X requires an adequate genetic counseling for the patients who are to be given information about the disease, any neurodevelopmental and psychological issues problems, as well as information on the risk of recurrence in a future pregnancy, which is <1% (4,10). Also, information will be provided about the possible occurrence of premature ovarian failure and the risk of 1-5% to have offspring with trisomy X or trisomy XXY (5, 12).

The **Aim** of our retrospective study was to make a genotype - phenotype correlation for a selected group of 36 patients diagnosed with trisomy X (homogeneous or mosaic) through cytogenetic testing (X chromatin and karyotype).

MATERIAL AND METHODS

Between January 1965 and December 2012, 36 patients were diagnosed cytogenetically with homogeneous or mosaic trisomy X (5.35% of the total of 672 patients evaluated for the presence of clinical signs evocative for an ovarian dysgenesis) in Iasi Medical Genetics Centre.

Clinical evaluation of patients included anthropometric measurements, assessment of pubertal development and evidence of clinical signs suggestive for a gonadal dysgenesis.

Cytogenetic evaluation included the *X chromatin test* (Barr bodies) and the G banding *chromosome analysis* (450-550 bands/metaphase). *The X - chromatin (Barr body)* was analyzed on buccal mucosa smear with at least 300 cells being analyzed (14). The karyotype was also performed in the presence of an abnormal test (frequency less than 10% of Barr bodies or presence of 2 or 3 Barr bodies). *Chromosomal analysis* based on a short-term culture of activated T-lymphocytes (72 hours) was performed according to the Moorhead technique (1960), adapted in our laboratory. Metaphases were examined by optical microscope and selected cells were karyotyped. For each case a minimum of 16 metaphases were analyzed. In cases of detected cells with different number of chromosomes X, the number of cells analyzed was increased to 32, 64 or even 96.

RESULTS

Based on the analysis of the karyotypes register of Cytogenetics Laboratory of the University of Medicine and Pharmacy "Grigore T. Popa" Iaşi, we identified 36 patients with trisomy X (homogeneous and mosaic) (tab. I).

In most cases (69.44% to 25 patients), there was a reference diagnosis related to a gonadal dysgenesis, and in three cases (8.33%) there were purimalformative syndromes.

We note that the clinical suspicion of triple X syndrome existed only in 2 cases (5.55%). We believe that this data can be correlated with phenotypic polymorphism of trisomy X.

The age of patients at diagnosis ranged from 1 month to 42 years. In prepubertal period (0-12 years) 11 cases were diagnosed (30.55%), 12 other cases (33.33%) were diagnosed during puberty (12-16 years) and 13 cases (36.11%) were diagnosed in the post pubertal period (over age 16) (tab. I).

The X chromatin test performed on buccal mucosa smear test (Barr body) was positive in all cases, revealed the presence of 1, 2 or 3 Barr bodies, and the results were compared with the chromosomal analysis results. In cases where a cell line with X monosomy was identified, the percentage of X chromatin test was positive, but low (<10%).

The karyotype was 47,XXX in 8 patients (22.22%), 46,XX/47,XXX in 6 cases (16.66%), 47,XXX/48,XXX in 2 patients (5.55%) and revealed various gonosomal mosaics containing a cell line with trisomy X and one line with X chromosome monosomy, in 20 cases (55.55%) (tab. I).

For patients diagnosed in the prepubertal period (0-12 years) the main clinical signs were growth retardation (90.9%) and facial dysmorphism with abnormally shaped ears (72.72%), thin lips (63.63%), hypertelorism (54.54%), epichantus (54.54%) and upslanted palpebral fissure (63.63%) with just only one patient having tall stature (9.09%). Moderate mental retardation was detected in 3 patients (27.27%) - all showing the karyotype 46,XX/47,XXX; only one patient presented borderline intelligence (9.09%) and karyotype 45,X/46,XX/47,XXX, while the remaining patients presented a normal intellect. In the case of a patient with mosaic 47,XXX/48,XXXX a psychomotor retardation was detected. Two patients had psychiatric disorders, and one was diagnosed with mosaicism 46,XX/47,XXX presented behavioural disorders (narcissism and masturbation). Other abnormalities detected were: skeletal (45.45%), genitals (36.36%), cardiac (18.18%) and reno-urinary (9.09%).

In cases of patients with trisomy X, diagnosed pubertal (12-16 years) and postpubertal (over 16 years) the main clinical signs were ovarian dysgenesis: late menarche (24%), delayed puberty (28%), reduced development of breasts (40%), reduced pubic hair growth (36%), reduced / absent axillary hair growth (40%), irregular menstrual cycles (24%), primary amenorrhea (24%) and secondary amenorrhea (20%). Postpubertary, facial dysmorphism was uncharacteristic with upslanted palpebral fissure (8 cases -32%), down-slanted palpebral fissure (4 cases -16%), abnormal ear shape (4 cases, 16%) and thin lips (5 cases -20 %). Tall stature was present in 20% of cases (5 patients), and growth retardation in 32% of cases (8 patients). Psychiatric disorders were present in 4 patients (16%), one of them having a free homogeneous trisomy 47,XXX and presenting sexual identity disorders without cognitive impairment.

DISCUSSION

The frequencies of the different types of chromosome abnormalities detected in our study compared to other studies are shown in Table II. We note that the frequency of trisomy 47,XXX (22.22%) was similar to

that detected by Robinson et al, 1982 - 18.03% (20), and the frequency of mosaic 45,X/47,XXX (25%) was similar to that detected by Sybert - 33.33% (19). For other types of mosaic trisomy X, the frequency varied in all three studies.

TABLE II

Frequency of chromosome abnormalities detected in female patients with homogeneous and mosaic trisomy X in the present study compared to other studies in the literature

Type of chromosomal abnormality	Present study	Sybert (19)	Robinson et al. (20)
Number of cases (%)	36	87	61
47,XXX	8 (22.22%)	-	11(18.03%)
46,XX/47,XXX	6 (16.66%)	-	2 (3.27%)
47,XXX/48,XXX	2 (5.55%)	-	-
45,X/46,XX/47,XXX	9 (25%)	68 (91.17%)	2 (3.27%)

45,X/46,XX/46,X,r(X)/47,XXX	1(2.77%)	-	-
45,XX,dic/45,X/46,XX/47,XXX	1(2.77%)	-	-

The characteristic phenotypic variability of trisomy X and reduced number of patients (36 cases) generated difficulties in genotype-phenotype correlations. These issues are compounded by the fact that there may be somatic mosaics undetectable in the absence of analysis of other tissues, respectively, the existence of patients with homogeneous trisomy X or cryptic mosaics undetectable in peripheral blood.

In prepubertal period the major clinical features were: growth retardation (small to medium), mild craniofacial dysmorphia and mild mental retardation associated with behavioral disorders. In the post pubertal period the elements suggestive for trisomy X were ovarian dysgenesis sometimes associated with mild mental retardation and psychiatric disorders.

Clinical signs detected in patients with homogeneous and trisomy X mosaic included in our study were similar to those presented in the literature. The only discordant element was in values of stature. Bibliographic data indicates the presence of a tall stature, detected in 80-89% of patients (1). From 8 patients with homogeneous trisomy X, 7 had normal stature and only one showed a slight decrease of stature (-1.5 SD), probably correlated with premature birth (15). Of the 6 patients with mosaic 46,XX/47,XXX, five showed a normal staturo-ponderal growth and one had tall stature (+1.81 SD). One of the 2 patients (2.85%) with polysomy X and mosaic 47,XXX/48,XXXX, presented a normal stature, ponderal hypotrophy (- 3.65 SD) and microcephaly (- 8.25 DS) associated with mild mental retardation, whereas patients diagnosed with polysomy X and

karyotype 47,XXX/48,XXX,+mar presented a tall stature (+ 3.86 SD), ponderal hypertrophy (+ 2.04 SD) and facial dysmorphism (hypertelorism, bilateral epichantus, upper lip eversion, macrostomia, dysplastic ears with preauricular tags or pits) and borderline intelligence.

Cognitive deficits associated with severe psychomotor retardation are rare in trisomy X, but 5-10% of cases may have a borderline intelligence with IQ = 85-90%, but overall IQ is lower than the first-degree relatives (1,16,17).

There are no serious mental disorders, but patients have issues with language and neuromotor development but this can be corrected with appropriate support from the family (17). In our study we detected an intellectual deficit with moderate mental retardation or borderline intelligence in 5 patients. Only 2 patients had psychiatric disorders manifested by neurasthenic syndrome and behavioural disorders (narcissism and masturbation) and one patient presented sexual identity disorders.

In patients with homogeneous polysomy X intellect is severely affected and sterility is are associated with disorders of sexual differentiation and dysmorphic manifestations (13), but this was not observed in our patients with mosaic polysomy X: 47,XXX/48,XXXX and 47,XXX/48,XXX,+mar.

The frequency of skeletal anomalies detected - 45.45% (5 cases) - was similar to that reported in the literature by Tartaglia et al, 2010 (1) - 42-65%. Only one patient (9.09%) presented urinary stasis and the frequency of reno-urinary had genital abnormalities and one of them presented an anal imperforation associated with rectovaginal fistula. The most common heart defect detected in patients with trisomy X were atrial and ventricular septal defects, pulmonary stenosis and aortic coarctation (1,18). Two of our patients had cardiac defects (atrial septal defect and mitral insufficiency, respectively, tricuspid insufficiency and mitral valve prolapse).

In 20 patients (55.55%) with gonosomal mosaicism having different cell lines with trisomy X and monosomy X, the phenotype was variable and correlated with the type and the proportion of cell lines present. Data from the literature show that 10% of patients with trisomy X have an abnormal mosaic, the most common being 46,XX/47,XXX or 47,XXX/48,XXXX or different gonosomal mosaics corresponding to Turner syndrome: 45,X/47,XXX or 45,X/46,XX/47,XXX (4.5). On the other hand, 3-4% of the patients diagnosed with Turner syndrome had a cell line with 47,XXX trisomy (1,19).

All 9 patients diagnosed with Turner syndrome and karyotype 45,X/46,XX/47,XXX had hypostature (between [-1.88] - [-3.75 DS]), normal intellect and absence of lymphedema in neonatal period. Four patients were diagnosed prepubertal, and 5 patients postpubertal, the main clinical signs in the latter being delayed puberty, primary amenorrhea and premature ovarian failure.

Sybert analyzed 17 patients with trisomy X mosaic and indicated that the average age of diagnosis in patients with trisomy X was higher than in Turner syndrome, most of the cases being detected in adulthood because of reproductive disorders. In patients with Turner syndrome having a cell line with trisomy X lymphedema was not detected and hypostature was identified only in 14% of patients. In addition, mental retardation was not identified in any of the cases with mosaic having a 47,XXX cell line (19).

In our study, in cases with karyotype 45,X/47,XXX (9 cases), neonatal lymphedema was absent and moderate hypostature was present in 7 cases. Two of the patients had borderline intellect. The diagnosis was established in the postpubertal period in 7 cases, and two patients were diagnosed in the peri pubertal period in the presence of a deficiency of secondary sexual characters.

The presence of spontaneous menarche in patients with trisomy X mosaic was detected by Sybert in 70% of cases, compared with 11% of patients with monosomy 45,X and 34% for those with mosaic 45,X/46,XX. Functional cell death is earlier than in normal women, generating secondary amenorrhea.

Often, the reproductive function is deficient, particularly correlated with primary sterility or increased frequency of spontaneous abortions (19).

In our study we identified two patients with pregnancy: one patient with mosaic 46,X,dic(X)/45,X/46,XX/47,XXX who had a stillborn baby with plurimalformative syndrome and one patient with 45,X/47, XXX mosaic whose pregnancy was terminated by miscarriage.

Unlike homogeneous trisomy X associated with deficits of learning, language and visual or auditory perception, in patients with mosaic trisomy X type 45,X/47,XXX or 45,X/46,XX/47,XXX, we I have not detected such issues, an aspect revealed by Sybert (19).

CONCLUSIONS

The results of our retrospective study, consistent with the literature, emphasize the difficulty of establishing a genotype - phenotype correlations for homogeneous and mosaic trisomy X.

Prepubertal, the diagnosis was established on the basis of growth retardation associated with uncharacteristic facial dysmorphism and mild mental retardation associated with behaviour disorders and, postpubertal, on by the presence of signs of ovarian dysgenesis associated with mild mental retardation and psychiatric disorders.

We emphasize the importance of Barr testing as a screening test in school age girls having borderline intellect or learning difficulties, that would allow early detection of trisomy X, thus enabling psychological, or psychiatric assistance, useful for social integration.

Early cytogenetic diagnosis of trisomy X would allow the female sex hormone replacement therapy, useful for improving socialization and, possibly the potential for reproduction

PERCUTANEOUS HERBERT SCREW OSTEOSYNTHESIS IN TRANS-SCAPHOID PERILUNATE FRACTURE-DISLOCATIONS

O. Alexa, B. Veliceasa
University of Medicine and Pharmacy "Grigore T. Popa" – Iasi

Discipline of Orthopedics-Traumatology

PERCUTANEOUS HERBERT SCREW OSTEOSYNTHESIS IN TRANS-SCAPHOID PERILUNATE FRACTURE-DISLOCATIONS (Abstract): Trans-scaphoid perilunate fracture-dislocation is the most common variety of fracture-dislocations of the wrist. Because of the carpal scaphoid fracture association, post-reduction stability is poor, often requiring surgery. Of the several surgical techniques used over time, percutaneous screw fixation for scaphoid fracture is currently preferred. **Material and methods**: Six cases of trans-scaphoid perilunate fracture-dislocation were surgically treated by percutaneous reduction of the scaphoid fracture and percutaneous insertion of Herbert screw in a proximal to distal manner. Postoperative immobilization was followed by rapid resumption of wrist mobility. Results: Four of the six patients have resumed normal, painless mobility of the wrist within 3 to 6 weeks post immobilization; in the remaining two cases there were a slight wrist stiffness attributed to persistent slight rotatory deficiency between the fractured scaphoid fragments. **Conclusions**: The percutaneous Herbert screw fixation provides a firm fixation with good compaction of scaphoid fracture, enough stability to allow minimal soft tissue and local damage, early mobilization following minimal immobilization, and thus rapid healing. **Keywords**: TRANS-SCAPHOID PERILUNATE FRACTURE-DISLOCATIONS, PERCUTANEOUS OSTEOSYNTHESIS, HERBERT SCREW.

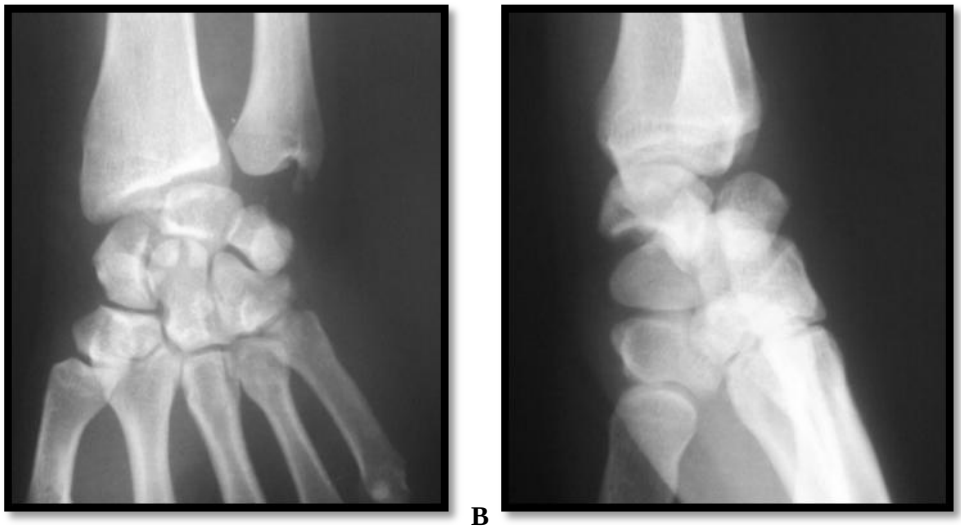
Trans-scaphoid perilunate fracture-dislocation**s** are the most common pattern of carpal fracture-dislocation (1, 2). These injuries can lead to poor functional results (3, 4) as a result of wrist arthritis; therefore, overtime, treatment was focused on anatomical fracture reduction, stable fixation and rapid mobilization.

Closed reduction and cast immobilization often result in loss of reduction (44% - 68%) and/or scaphoid nonunion (23% - 27%) (5). Therefore, open reduction and internal fixation seem to be a reasonable alternative to the previous technique, but these methods are accompanied by soft tissue damage by extensive dissection and implicitly interruption of vascular supply.

Other techniques used in these fracture-dislocations were closed reduction with percutaneous fixation of the fracture, the advantages being minimal dissection, stable fixation and early mobilization. Initially, these techniques used Kirschner pins, but as these did not provide adequate interfragmentary compression cannulated screws that were successfully used in isolated fractures of the scaphoid were preferred (6).

MATERIAL AND METHODS

In the interval August-December 2012 6 patients presented to our unit with trans-scaphoid perilunate fracture-dislocations, the fracture line separating the scaphoid proximal pole from scaphoid body. Patients were aged 19 to 34 years; the incriminated mechanism was fall exerting an axial load with hyperextension and ulnar deviation of wrist. For diagnosis we used the Mayfield classification, five cases being stage 2 (fig. 1) and one stage 4.



A **B**

Fig. 1. Wrist radiography (A - anterior-posterior and B – lateral views): trans-scaphoid perilunate fracture-dislocation Mayfield stage 2

In all cases the course of treatment consisted in emergency closed reduction of the carpal dislocation and plaster splint immobilization.

Post-reduction, radiological control showed in most cases a persistent misalignment between forearm bones and the first row of carpal bones and between the first and the second row of carpal bones observable by Gilula line interruption (fig.2). This was attributed to the imperfect reduction of the scaphoid fracture, causing dislocation instability and requiring surgery. To avoid extensive dissection, given its local vascular implications, we preferred a minimally invasive technique that consisted in percutaneous reduction of the scaphoid fracture and its fixation with a Herbert screw.

There was generally a waiting period of 4-7 days, while the hand was immobilized in brachiopalmar, proclive plaster splint; inflammatory and analgesic treatment was instituted. During this period edema had resolved facilitating our attempts at closed reduction of the scaphoid fracture.

Surgery was performed under loco-regional anesthesia (infra-clavicular plexus). Orthopedic fracture reduction was achieved and maintained with a temporary percutaneous olecranon forceps. A guide pin was introduced through the scaphoid tuberosity, then advanced to the proximal pole and exteriorized on the dorsal wrist, later serving to the introduction of the Herbert screw in proximal to distal direction (fig. 3).

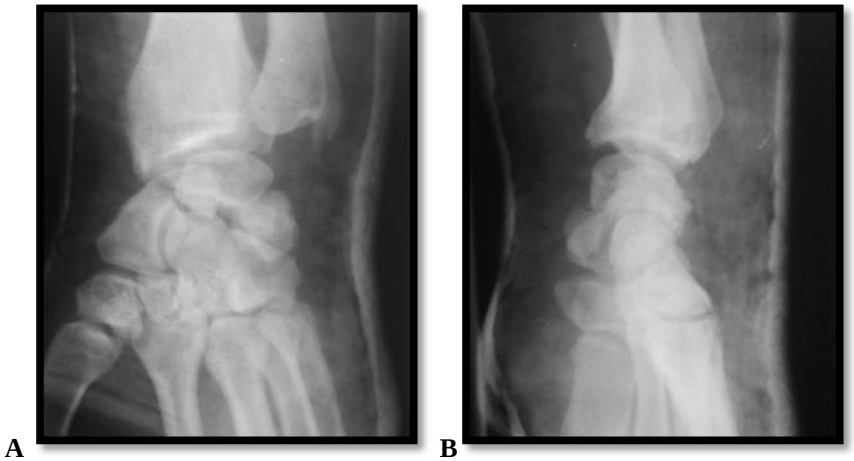


Fig. 2. Post-reduction wrist radiography: A - anterior-posterior view - reduction of the scaphoid fracture with interfragmentary diastasis and maintaining a persistent interruption of Gilula lines, B – lateral view – reduction of the trans-scaphoid perilunate fracture-dislocation.

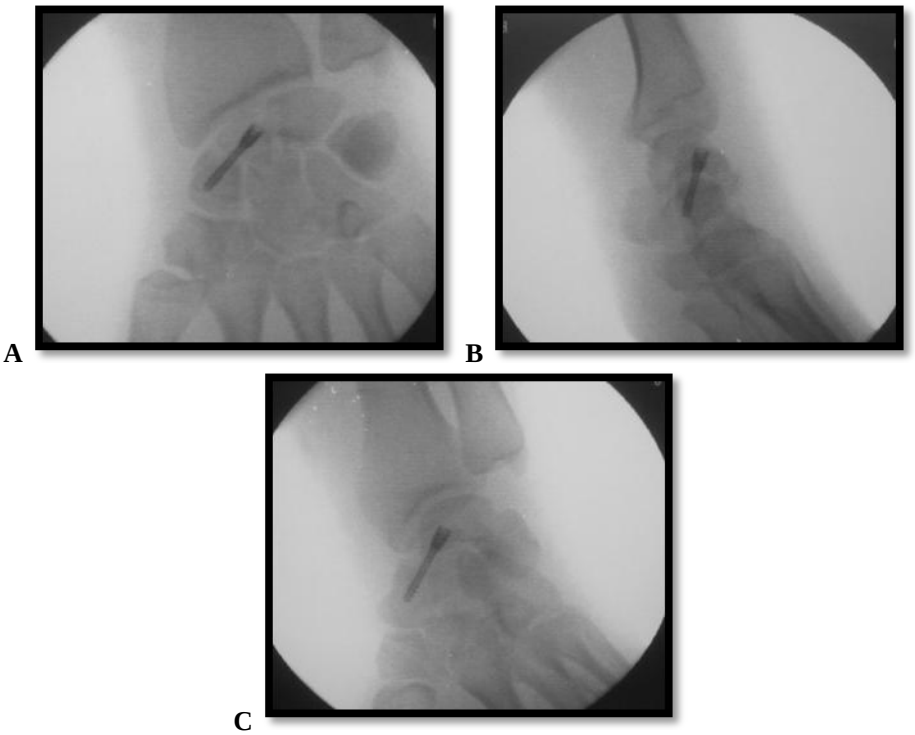

Fig. 3. Post-surgery wrist radiography: A - anterior-posterior view, B – lateral view, C – scaphoid view): good reduction of scaphoid fracture with compactness and good alignment between the carpal bones

Dislocation stability was then examined, only one of the six cases requiring additional stabilization with Kirschner pins. Post-reduction, in two of the six patients there was a slight rotator deficiency between the fractured scaphoid fragments.

Postoperative immobilization consisted of brachiopalmar plaster splint kept for 3 weeks and antebrachiopalmar plaster splint for another 3 weeks, followed by physiotherapy.

Four of the six patients have resumed normal, painless mobility of the wrist within 3 to 6 weeks post immobilization; in the remaining two cases there were a slight wrist stiffness attributed to persistent slight rotator deficiency between the fractured scaphoid fragments.

DISCUSSION

Currently, most authors believe that for best results, all dislocations or perilunate fracture-dislocations of the wrist must be reduced and rigidly fixed as soon as possible. It is sometimes necessary to delay definitive treatment because of the general condition of the patient, excessive swelling of the hand and wrist, or the need for adequate surgical care.

Hee et al. (8), in 1999, in a study on16 cases with trans-scaphoid perilunate fracture-dislocations obtained good results by open reduction and fixation with Herbert screw or Kirschner pins alone or with screw. Inoueet al (9) in a study of 29 patients treated by open reduction and internal fixation with Herbert screw observed good functional results in patients immobilized for 4 weeks postoperatively compared to those immobilized for more than 5 weeks.

Lam et al. (10) introduced in 2002 the cannulated percutaneous screw fixation of the scaphoid fracture, a difficult technique that can be an alternative to open reduction technique of recent trans-scaphoid perilunate fracture-dislocations.

Wong (11), in 2008, in a retrospective study of 21 patients treated by closed reduction of the carpus dislocation associated with closed reduction and percutaneous screw fixation of scaphoid fracture followed by closed reduction and stabilization with Kirschner pins of the carpal dislocation obtained an average Mayo score of the wrist of 80, with three excellent and two poor results, concluding that minimally invasive techniques can be considered a good reverse shuttle to open techniques.

Excellent results with minimally invasive techniques were reported by Chouet al. (12). They used in a series of 24 patients a technique involving percutaneous screw fixation of the scaphoid fracture and axial fixation with Kirschner pins of the carpal dislocation performed 7 days after injury. Clinical results were evaluated based on the range of motion, pain, functional status, and Mayo scores, the authors concluding that this technique is an appropriate treatment for acute trans-scaphoid perilunate fracture-dislocations of the carpus.

CONCLUSIONS

The percutaneous technique with Herbert screw offers a good protection of soft tissue with minimal local implications and firm fixation, good compaction of scaphoid fracture providing a rapid healing with good stability post-reduction, with minimum immobilization and possibility of early mobilization.

NEWS

OLFACTORY DYSFUNCTION AND NEURODEGENERATIVE DISORDERS

Olfactory dysfunction is common, about 5% of the general population having anosmia and becomes more common with advancing age. Since many patients with neurodegenerative diseases - including Parkinson's or Alzheimer's - have early olfactory loss, testing for disturbances of the sense of smell is becoming important in neurology. Olfactory dysfunction is considered an early sign of neurodegenerative disorder that may facilitate diagnosis years before the onset of motor or cognitive disturbances. The use of anti-inflammatory drugs, surgery and olfactory training can help as the treatment for olfactory loss. (Hüttenbrink KB, Hummel T, Berg D, Gasser T, Hähner A. Olfactory dysfunction: common in later life and early warning of neurodegenerative disease. *Dtsch Arztebl Int*. 2013; 110(1-2): 1-7. doi: 10.3238/arztebl.2013.0001).

2. Discipline of Pharmacology

ALZHEIMER – CERTITUDES AND HYPOTHESES (Abstract):Alzheimer's disease is a degenerative, progressive and irreversible condition, which affects cognitive functions. It was first described in 1907, by the German physician Alois Alzheimer. Although at the time, it was considered a rare disease, in 2010 in the world were estimated 35.6 million cases of dementia, most of these with the diagnosis of Alzheimer's disease. Typical neuropathologic lesions are represented by the amyloid plaques, neurofibrilar tangles and synapses and neurons losses. It was hypothesized that the amyloid protein has prion-like properties. Even from the first descriptions of the disease, atypical features were observed – the second case described by the physician Alois Alzheimer, had only plaques, the tangles were missing. About 19 % of the healthy old subjects present in the brain the same lesions as Alzheimer's cases, while in 10 % of the cases of disease, in necropsy are present only the plaques or only the tangles. These aspects are even more paradoxical, as the certain diagnosis is established only at necropsy, on anatomopathological lesions. Even so, the international diagnosis criteria, based on clinical aspects, can establish a certain, probable or a possible diagnosis. It exist an early-onset form, as well as a late-onset form of disease (which appears after 80-85 years of life); genes are involved in the genesis of the disease. A lot of money are spent to find an efficient medication in the treatment of the disease (tramiprosate – an amyloid-antagonist, Dimebon, gamma-secretase inhibitors or a vaccine – a synthetic form of the amyloid protein); for the moment the used medication may at its best only to temporary improve the symptoms. Some scientists believe that approx. 30 % of the cases are wrongly diagnosed with Alzheimer, being in fact other forms of dementia, or that we deal with several biologic processes, generating rather an Alzheimer's syndrome, meanwhile others are unsatisfied by a poor diagnosed disease and its popular receipt as a part of the normal aging process. **Keywords**: ALZHEIMER'S DISEASE, DEMENTIA, AMYLOID PLAQUES, NEUROFIBRILAR TANGLES, AMYLOID β PEPTIDES.

EPIDEMIOLOGICAL LANDMARKS, HYPOTHESES AND CONTROVERSIES

Being a degenerative, progressive and irreversible disease, which is dramatically damaging the intellectual functions, the Alzheimer's disease was first described in 1907, by the German physician Alois Alzheimer, being then considered a rare entity. Now is considered an epidemical disease, with major social impact, and which threatening is growing together with the phenomenon of global aging of the human population.

2009 World Alzheimer Report has estimated 35.6 million dementia affected individuals for 2010, and this number was estimated to double at each 20 years, thus resulting 65.7 million in 2030 and 115.4 million in 2050. Large part of this growth is attributed to the increase in number of the dementia affected people in the countries with low and medium incomes/inhabitant. In the same report, the specialists are underlying the under diagnosis of this disease, as well as the stigmatization of the affected people and of their families, all over the world, independent of the size of the country, or the level of wealth. Alzheimer's disease was diagnosed in all the countries, of any culture and race, in which the diagnosis screening was done. The level of awareness of the disease, as a severe medical condition is greatly variable, from one country to another. In low and medium developmental level countries, the degree of awareness is decreased, dementia being still considered a normal estate of the normal aging process (1).

Recognized risk factors are: the advanced age, the genotype Apo E epsilon 4, cranial trauma, cardiovascular risks (smoking, diabetes, high blood pressure, and hyper cholesterolemia), and possible metal exposure, especially to aluminum. The gene for the E apolipoprotein on the 19 chromosome is a protein, which is modulating the transport of the phospholipids, with role in the synaptic remodeling. Apo E epsilon 4 is associated with a high risk for Alzheimer's disease (3).

Classical neuropathological features

- amyloid plaques and neurofibrilar tangles, with synapses and neurons losses.

- granulovacuolardegenerescence of the hypocampus and deposition of amyloid in the vessels, are usually present as well.

- the amyloid plaques are made of 40-43 aminoacidsoligopeptides, derived through proteolysis from a much larger precursor amyloid protein fraction – APP – amyloid precursor protein. The precursor protein is coded by a single gene and is made of several sequential forms, fractions of the plasma membrane integral proteins type I. The amyloid is made of 28 aminoacids of the big extracellular aminoterminal domain of the APP and of the first 12-15 aminoacids of the intramembranary region.

- the associated microtubular tau protein, under a hyperphosphorylated, modified form, is the major protein component of the spiralated filaments in the structure of the neurotubules, thus in the structure of the neurofibrilar tangles. The normal tau protein is not glycosilated, while in the brain of the Alzheimer's patients, this protein appears under a glycosilated form. Although the abnormal phosphorylation is leading to the inhibition in the assembly of the microtubules, the glycosilation is mantaining the helical structure. Normal tau protein is involved in the axonic growth. The abnormal phosphorylated form of the tau protein is forming the spiralated filaments pairs of the neurotubules, and it appears in the neurons of the hippocampus, medial temporal lobe, parietotemporal region and in the associative frontal cortex, leading to the death of the interneurons. These zones are affected by the loss of the synapses, with the injury of the synaptic passages of the neurotransmitters (2).

- mutations at the level of three proteins – presenilin 1, presenilin 2 and the precursor protein of the β amyloid, were identified in the familial form of the Alzheimer's disease. These mutations are increasing the extracellular concentration of the β amyloid and are enhancing its brain deposition (3).

ETIOPATHOGENIC HYPOTHESES

1. Although the hypothesis which is stating that the β amyloid peptides (Aβ) are the primary causal agents of the Alzheimer's disease is supported by the large majority of the researchers, a large number of data is showing that it is rather unlikely, the Aβ peptides to be the single etiologic factor of the disease.

2. There are proofs which support the fact that factors which are unrelated to amyloidosis, including genetical factors, are important in the pathogenesis – defects of the endolysosomal metabolism, the alteration of the intracellular signal cascades, damaging in the releasement of the neurotransmitters, are all contributing to the appearance of the synaptic dysfunctions and/or neurodegenerescence and hence to the dementia of the Alzheimer's disease (4).

3. A hypothesis is launching the possibility of the development of the neurofibrilar tangles, as a result of the age-related dysfunction in the function and viability of the microglial cells. The neurodegenerescence would be from this point of view, the result of a decline of the immune functions, rather than a hyperactivity of of the immune system (5). The death of the cholinergic neurons of the Meynert basal nucleus is resulting into the deficiency of acetylcholine, characteristic for the disease; a transmitter involved in the memory process (7). The loss of the serotoninergic neurons of the median zone of the raffe and of the adrenergic neurons of the locus coeruleus is determining the serotonin and the norepinephrine deficits. The exact role of the inflammation in the pathogenesis of the disease is still controversial; although studies which evidentiate the microglial activation do exist (as a marker of the brain immune response), prednisone, as well as NSAID (non steroid alantin inflammatory drugs) were ineffective in the treatment of the disease (6).

4. New studies have even proposed a prionic hypothesis in the pathogenesis of the Alzheimer's disease. It was noticed that the peripheral deposits of beta-amyloid, from different tissues, others than the brain, may finally reach „to infect" the brain. Injection of the amyloid-containing brain tissue, obtained from old mice, in the abdomen of younger animals, had led several months later to the detection of the amyloid in the brain of younger injected animals. The studies which used transgenic mice (genetically induced to produce Aβ human amyloid) had led to the prion-like qualities of the amyloid protein hypothesis. Prions show protein structure and are transmissible, as it is happening in the Creutzfeld-Jakob disease. Yet, there are no proofs that the Alzheimer's disease or the brain amyloid angiopathia are transmissible (between mammals or humans) in the same way as the prionic diseases (8).

DIAGNOSIS – DISEASE OR SYNDROME ?

The diagnosis is established upon the clinical criteria stated by the National Institute of Neurological and Communicative Disorders and the Alzheimer's Disease and Related Diseases Association, in the USA. It is estimated that these criteria are establishing the diagnosis, with an accuracy of 90 %. On the basis of these criteria, the diagnosis is certain, probable, or possible, but the certitude of the diagnosis is obtained only through necroptic examination of the anatomo-pathologic lesions. Nevertheless, were signaled cases of subjects with minor memory troubles, but who had

typical Alzheimer's disease lesions, in necropsy.

The major clinical manifestation is represented by the memory loss, first for the recent events, but afterwards for the past events, as well. Language troubles are first manifesting by the search of the right words, to name different objects, evolving into communication disability, limited vocabulary, nominal aphasia and difficulties of understanding.Apraxia is developing (the inability to perform simple daily activities, such as combing the hair), acalculia (the inability to perform simple arithmetic calculations) visual and spatial disorientation (disorientation in what concerns the position in space of the body).

The mood troubles are including depression, anxiety, apathy, which may appear early in the development of the disease, while in the advanced stages, hallucinations are frequent, together with psychotic symptoms; aggressiveness and sexual behavioral troubles are most unpleasant for the caring persons. In the advanced or terminal stages, is appearing the frontal lobe syndrome, and the sphincters incontinence, myoclonus, convulsions, up to the vegetative estate, when all cognitive activities are disappearing (10).

Ten cardinal symptoms
of the Alzheimer's disease

- decline of the rational thinking
- difficulties in accomplishing complicate tasks
- language troubles
- time and spatial disorientation
- decline of the abstract thinking
- loss of the recent memory affecting daily tasks
- personality changes
  mood and behavior troubles
- changes in perception of the reality
  loss of the initiative

MRI examination is revealing the progressive atrophy of the hippocampus, which is an important zone of the memory processes (10). Dosages of the Aβ peptide and of the tau protein, in the cerebrospinal fluid, are considered biomarkers for the Alzheimer's disease, being estimated that their use, will increase the accuracy of the diagnosis. Decrease of the levels of the Aβ peptide and increase of the tau protein, in the cerebrospinal fluid, are the proof of the evolution of the disease, being the consequence of the deposition of the amyloid peptide into the brain, and of the excretion of tau protein by the neurons which undergo degenerescence (11).

Anatomopathologic lesions, which represent the certitude diagnosis, might be present in healthy old-aged subjects (19 % among these), as well as in subjects who developed another type of dementia. In the necroptic examination, in about 10 % of the cases of Alzheimer's disease are present only the amyloid plaques (otherwise, the second case described by Alois Alzheimer had only plaques in necropsy), or only the neurofibrilar tangles.

The book written by dr. Peter Whitehouse and Daniel George, „The Myth of Alzheimer's: What You Aren't Being Told about Today's Most Dreaded Diagnosis" (2010, http//booksandideas.com) is putting the question whether the concept itself of Alzheimer's disease is clear enough, and if there are not rather several different pathologic processes, since not even A. Alzheimer was not sure that he had described something different from the senile dementia. Dr. Whitehouse is considering that too often, this is a label, in the same way like that of dementia, and that it must be reevaluated in what measure the

Alzheimer's lesions are not a part of an individual aging process.

Early onset and late onset Alzheimer's concepts appeared as a consequence of the fact that, the majority of the Alzheimer's disease diagnoses are now established in patients over 85 years old, while the cases described by Alzheimer were relatively young – 51, respectively 54 years old. Even in the early onset forms, it is difficult to state that the pathologic process is really distinct, from that one in the senile dementia.

Based on the similarity of the brain lesions, in the sixth decade of the XX century, especially under the pressure of the Anglo-Saxon specialists, the concepts of Alzheimer's disease and that of senile dementia were unified. This contributed to the perception of the Alzheimer's disease as a separate medical condition, since the term of senile dementia had such deep negative connotations. There are differences in the symptoms of the two types of Alzheimer's disease – in young patients, the troubles of language, gesture, recognition of faces/objects are predominating, while in the case of old-aged patients, memory troubles are clearly predominating. There are studies which conclude that approximately 30 % of the Alzheimer diagnosed patients do have in fact, another type of dementia.

There are voices who state that we should talk about the „Alzheimer's syndrome", which would include several types of diseases (12, 13).

THERAPY, BETWEEN FAILURES AND PROMISES

Among the factors which decrease the risk for Alzheimer's disease, with some degree of efficiency is signaled – the brain stimulation (examples – chess, puzzles) and regular physical exercise (14, 15, 16). The therapy is targeting on one hand to reduce the risk of development of the disease, by using food supplements, NSAID (such as aspirin, ibuprofen, which unfortunately in several studies, did not prove to be efficient) and the treatment of the acetylcholine deficit, by administration of cholinesterase inhibitors and antagonists of the receptor N-methyl-d –aspartate (NMDA) on the other hand, and experimental medication, hoped to be a real revolution in the therapy of the disease.

Some studies investigated the real prevention efficiency of group B vitamins, of high doses of E and C vitamins, of the choline, omega 3 fatty acids (DHA), of the statines and NSAID; unfortunately, the results were not those which were expected (17,18,19).

Cholinesterase inhibitors (Donepezil, Rivastigmine tartrate, Galantamine) and the antagonists of the receptor – NMDA - (Memantine – Namenda) are determining only a temporary improvement of the cognitive functions, and of the behavior (20).

From the recently experimented medications, Tramiprosate, an oral administration, small molecule antagonist of the amyloid, is considered promising; this is linking the soluble amyloid β peptide (Aβ) thus interfering with the cascade effect of the amyloid, its deposition, and with the brain toxic effects of the peptide. The signaled side effects were mild – mouth dryness, slight depression and increase of the sweat secretion (21).

Dimebon is another small molecule, with oral administration, which was commercialized in Russia in the 80^{s}, for its antihistaminic properties and was dropped off, as other superior antihistaminic agents were

developed. 70 % of the Alzheimer's patients who took Dimebon for one year, have improved their estate, or at least have stabilized their Alzheimer's symptoms (22).

Gamma-secretase inhibitors – LY 450 139, were developed by the Eli Lilly company as a modifier of the disease evolution; the medication inhibit the gamma-secretase, enzyme involved in the formation of the Aβ peptide. From 51 patients who received a 100/140 mg daily dose, for 6-12 weeks, in 43 cases who finished the trial, was registered the marked decrease of the blood Aβ levels (58.2% from those who received 100 mg/day and 64.6 % from those who received 140 mg/day). Minor side effects, such as rash, fatigability and sleepiness appeared (23).

A new approach in the Alzheimer's disease was to furnish an alternative source of energy to the glucose-deprived neurons. Ketasyn (AC-1202) is providing ketonic bodies to the glucose-deprived neurons; they can be metabolized, even when glucose cannot be. AC-1202 is converted into ketonic bodies (beta-hydroxibutirate) as a glucose-alternative for the energy-compromised neurons. Good results were obtained in patients who had not the E4 variety of the apolipoprotein gene (ApoE epsilon 4) which appears in half of the Alzheimer's disease patients. AC-1202 has significantly improved the memory and the cognitive capacity in negative ApoE 4 patients. The subjects who took AC-1202 for 9 months have registered a very small progress of the disease. The side effects were minimal; sometimes appeared gastro-intestinal troubles (24).

In the case of the vaccine AN 1792, which uses a synthetically form of the amyloid's protein, some patients developed an aseptic meningo encephalitis, reason for which the trial was stopped. In 59 patients, anti Aβ antibodies had detectable levels after 4.5 years; it was observed a more reduced dependence on the caring personnel and a slower decline of the memory tests. Among the vaccinated patients who developed antibodies, 75% did not need institutionalization, being able to remain at home, compared to only 53% in the placebo group. The necroptic studies of the deceased cases, after the finalization of the trial, showed reduced deposition of amyloid in the brain. Now are conducted experiments to elaborate safer vaccines. It is unknown why not all the vaccinated cases responded to the vaccine; probably the particular features of the aging process and the individual variability of the immune system are making the difference (24).

There are numerous studies which investigate the prophylactic and curing potential of plants, used in the traditional medicine (chinese, indian, european) in Alzheimer's disease. *Ginkgo biloba* has the property to neutralize the neurotoxic effect of the amyloid peptides, largely attributed to its antioxidant action. Galantamine, an alkaloid of the Amarylidaceae family was used in the southern Russia and in Bulgaria in the treatment of the poliomyelitis; its properties of acetylcholinesterase inhibitor were signaled in the fifties and consequent studies had led to the commercialization of Galantamine. Different components from *Panax ginseng, Lyciumbarbarum, Uncaria rhyncophylla, Yokukansan* and a lot of other plants, used in the oriental traditional medicine, as well as *Salvia officinalis, Crocus sativus* (saffron), *Mellisaofficinalis*, used in the european traditional medicine, proved useful in the therapy of the memory troubles and in the improvement of the cognitive dysfunctions of Alzheimer's

disease (25) .

While some researchers are deploring the insufficient financing of the research efforts in the Alzheimer's disease (for example the winner of The Nobel Prize for medicine for 2010, Robert G. Edwards), others, like dr. Peter Whitehouse, believe that in fact Alzheimer's disease is overestimated and should be considered an aspect of the aging process.

MOLECULAR EPIDEMIOLOGICAL SURVEILLANCE FOR TUBERCULOSIS BY WHOLE GENOME SEQUENCING

Tuberculosis (TB) is a contagious disease caused by *Mycobacterium tuberculosis* characterized by a high rate of incidence and mortality worldwide. Although the World Health Organization (WHO) established a global program for controlling and monitoring tuberculosis, the decline in the number of cases has been slow. Thus, the TB control strategies have targeted the development of molecular techniques to monitor disease transmission. Genotyping methods analyzed a small part of the bacterial genome for specific identification of strains, but they may not be able to determine the origin a tuberculosis outbreak or how it spread in population. A longitudinal molecular epidemiological study conducted by Niemann and collaborators showed that whole genome sequencing (WGS) provides more information about transmission chain of TB than classical genotyping methods: IS6110 RFLP (restriction fragment length polymorphism) and 24-locus MIRU-VNTR (mycobacterial interspersed repetitive unit–variable number of tandem repeats). The authors a study demonstrates that WGS is able to characterize clinical isolates with high discriminatory power, at strain level. Using WGS method, the researchers have estimated that the *M. tuberculosis* has a time-dependent genomic variation with a rate at 0.4 mutations per genome per year and with a doubling time of 22 hours, or 400 generations per year. Based on the results of the study, the same authors concluded that, in the context of decreasing sequencing costs, WSG can be an effective method for TB surveillance by identification of outbreak-related transmission chains (Roetzer A, Diel R, Kohl TA et al. Whole Genome Sequencing versus Traditional Genotyping for Investigation of a Mycobacterium tuberculosis Outbreak: A Longitudinal Molecular Epidemiological Study. *PLoS Medicine*, 2013;10:e100138 DOI: 10.1371/journal. pmed.1001387).

FAMILIAL SYNDROMIC PAPILLARY THYROID CARCINOMA - REPORT OF TWO CASES (Abstract) **Aim**: to describe two cases of familial papillary thyroid carcinoma. **Material and methods**: patients were investigated by fine needle biopsy, MRI imaging and tumor biopsy, (first case) and histological examination of colonic and thyroid tumors (first case) and histological examination of thyroid tumor (second case). **Results and discussion**: case presentation: first case, 68 years old man had a colonic polyposis (attenuated form with only a few polyps) and a thyroid nodule. After hemicolectomy for a supposed colonic carcinoma with liver and lung metastases, histological examination revealed no malignant colonic disease. Two month later the diagnosis of invasive thyroid tumor with lymph node metastases was made, but only an open biopsy was done because tumor invasiveness demonstrated on MTI imaging. The biopsy identified a papillary thyroid carcinoma. Case 2: the son of the patient (30 years old) without known diseases was invited to be assessed for thyroid disease. Ultrasound examination discovered a large nodule with microcalcifications. Microscopic examination done after total thyroidectomy revealed a cribriform morular variant of papillary thyroid carcinoma, a variant that is known to be associated with FAP. Radioiodine ablation was made followed by suppressive thyroxine treatment. In the second case adenomatous polyposis was not found yet. In our knowledge these are the first cases of familial thyroid papillary carcinomas in our setting. Familial history allowed an earlier diagnosis and a good management of the disease in the second case. **Conclusions**: according to the literature and our first experience, screening for thyroid cancer must be done in all patients with FAP and in those with a FAP proband in the family. **Keywords**: FAMILIAL NONMEDULLARY THYROID CARCINOMA, FAMILIAL ADENOMATOUS POLYPOSIS, CRIBRIFORM, MORULLAR VARIANT, PAPILLARY THYROID CANCER.

Follicular-derived thyroid cancer represents 60-95% of all thyroid malignancies and at least 5 % of the patients have familial disease (1). Familial nonmedullary thyroid cancer (FNMTC) may be classified into two categories (1, 2, 3, 4): a. Non syndromic familial tumor syndromes with preponderance of FNMTC: familial papillary thyroid

carcinoma (FPTC) with or without oxyphilia, FPTC associated with renal papillary renal neoplasia, FNMTC type 1. b. Syndromic familial tumor syndromes in which nonmedullary thyroid carcinoma occurs with a known frequency: familial adenomatous polyposis – FAP and Gardner's syndrome, PTEN-hamartoma tumor syndrome, Carney's complex and Werner's syndrome.

Familial adenomatous polyposis (FAP) and Gardner's syndrome (a FAP variant) are produced by a loss of function germline mutation of APC (adenomatous polyposis coli) gene, a tumor suppressor gene located on the chromosome 5q21(2) . First mutation of APC gene was described in 1991 and 800 mutations were identified thereafter (5). It is an autosomal dominant disease with an incidence which varies between 1/8300-1/11300-1/37600 which may be responsible for up to 1% of colonic cancers. Classic form develops in the second decade of life and is characterized by occurrence of hundreds or thousands of adenomatous colonic polyps. Attenuated FAP shows fewer polyps, occurs later in life and carries a lower risk of colonic cancer (6). Extracolonic diseases occur in 70 % patients with FAP (5).

First case of an association between FAP and thyroid cancer was reported by Crail (quoted by Half 2009(6)). FAP-associated thyroid cancer occurs especially in women, at young age, and has a particular histology (2, 7, 8). Women with FAP have a 160 times higher risk developing thyroid cancer compared with general population (6).

FAP-associated thyroid carcinoma is a syndromic form of FNMTC and occurs with the following reported incidence: Nose V. 2012 2-12% (2), Herraiz M et al. 2007: 7 % (9), Steinhagen E. et al 2012: 6.1 % (10), Harb WJ and Sturgis EM 2009: 5%(11), Jarrar AM et al 2011: 2.6 %(12). These incidences are considered high enough to justify screening for FNMTC in all patients with FAP (Nose V 2011) by ultrasound neck examination and fine needle biopsy (FNB) even in small nodules (9).

Histological appearance of FAP-associated NMTC is similar in close relatives (13) and has a cribriform morular pattern with papillary architecture, morula formation, cribriform pattern with solid areas and spindle cells (7, 14, 15, 16). Preoperative diagnosis may be suspected on fine needle biopsy which shows columnar cell with fine to granular chromatin, nuclear grooves, papillary and acinar fragments (17). Immunohistochemistry on FNB and histological specimens allows detection of accumulation of beta-cathenin in cytoplasma and nucleus which is characteristic for APC mutation (18).

The known association between FAP and NMTC allows an earlier diagnosis by screening for thyroid cancer in FAP-confirmed patients and an earlier diagnosis of FAP in patients with cribriform morular variant of papillary thyroid carcinoma(13). Cribriform morullar variant of FAP-associated thyroid carcinoma usually has an indolent course, rare metastases and a good prognosis (2).

MATERIAL AND METHODS

Patients were investigated by fine needle biopsy, MRI imaging and tumor biopsy, (first case) and histological examination of colonic and thyroid tumors (first case) and histological examination of thyroid tumor (second case).

CASE PRESENTATION

Case no. 1. A male patient of 68 years with complains of alternative diarrhea and

constipation was submitted to colonoscopy in December 2011 in the Clinic of Gastroenterology of "St. Spiridon" Universiy Emergency Hospital. At 30 cm from anal edge a semipediculated polyp was identified and removed. In the proximity of the hepatic angle of the colon a large polypoid tumor was found and a superficial biopsy was performed. Histological examination of both specimens performed in the Laboratory of Pathology of the same hospital showed tubular adenomatous polyps with polymorphic inflammation and absence of malignant lesions (fig. 1).

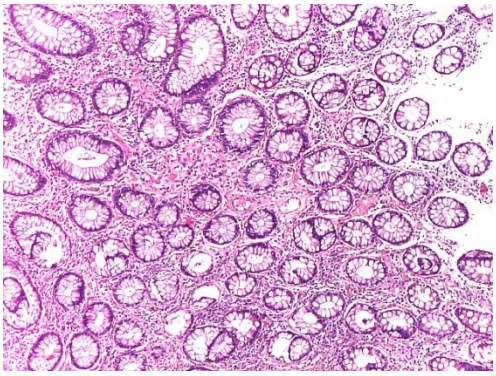

Fig. 1. Case 1. Polyp removed at 30 cm. from the anal from the edge: tubular adenomatous polyp with superficial erosions and important inflammation without signs of malignancy

The patients postponed surgery until 2 month later when he was admitted in emergency in the IstSurgery Clinic of the aforementioned hospital for diffuse abdominal pain and absent of intestinal transit for less than 24 hours. At physical examination a large, painful tumor mass was detected on the right side of the abdomen. Abdominal X-ray showed liquid and air levels suggesting an occlusive state and chest X-ray showed lung nodules with an appearance of metastases. Liver ultrasound detected multiple nodules also considered to be metastases from a colonic cancer Physical examination also identified a firm thyroid nodule of 6 cm its largest diameter, belonging to the left thyroid lobe, with preserved mobility on the neck structures and absence of compressive symptoms. The patients were operated in emergency. During surgery a colonic invagination took place due to an intraluminal tumor of 11 cm. the largest diameter, situated in the proximity of hepatic angle. Right hemicolectomy and resection of 13 cm of the terminal ileon, and ileal-transversal anastomosis were performed. Most lymph nodes in the area were carefully removed. An extensive macroscopic of the surgical specimen showed a large polypoid tumor mass, partially ulcerated which in microscopic examination had fibroblastic axes covered by ovoid cells, plasmocytes and eosinophils. All lymph nodes removed showed only histiocytosis. The patient came after 8 week and his diagnosis of colonic carcinoma with liver and lung metastases was revised by the surgeons and their attention was directed toward the thyroid nodule as a possible carcinoma. This time, the thyroid nodule was larger, both thyroid lobes strongly attached to the trachea, and bilateral lymph node enlargement was detected by clinical examination and neck ultrasound. Fine needle biopsy brought small micropapillary structures, thyroid cells with large nuclei, nucleols and cytoplasmatic intranuclear inclusions (fig. 2). The attempt to remove the tumor failed and only a large biopsy was possible. The diagnosis was papillary thyroid carcinoma (fig. 3). With the diagnosis of stage T4N1Mx papillary thyroid carcinoma, the patient was transferred to the Clinic of Endocrinology of the same hospi-

tal. MRI examination confirmed the presence o large thyroid tumor (7.2 x 4.5 x 3.5 cm), developed also between the thyroid and cricoid cartilages, infiltrating left vocal cord, the esophagus on a length of 13 cm, and muscles and fat around it. All lymph node compartments surrounding the thyroid presented enlarged lymph nodes between 1.2 and 7 cm (fig. 4). The hormonal profile of the patient was normal: TSH=2.86 μIU/ml, FT_4= 11.93 pmol/ml. In these circumstances the patient was placed on suppressive therapy with T_4 and X-ray therapy was indicated for palliation.

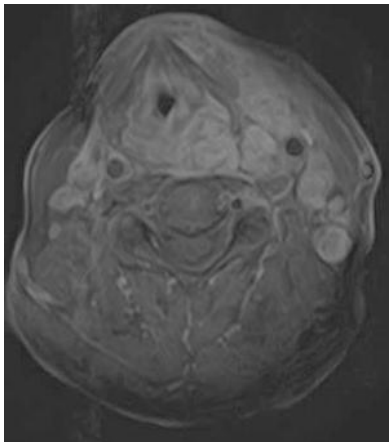

Fig. 4. Case 1 MRI examination of the neck: sections T1 axial Fat Sat + ivc: tumor extension between thyroid, cricoids and arytenoids cartilages producing reduction of laryngeal vestibulum. Large lymph nodes anterior from thyroid cartilage, bilaterally near the jugular vein and posteriorely.

Case no. 2

During the time when the first described patient stayed in the Clinic of Endocrinology, his son of 40 years old was informed that he carries a certain risk de have a thyroid disease and asked for permission to be examined for that. A physical examination, a large thyroid nodule was found in the right thyroid lobe. The patient was not aware of it before examination. Neck ultrasound identified a large inhomogeneous nodule of 3.9 x 5.3 x 2.9 cm with high vascularity and microcalcifications. Important blood contamination made the FNB specimen inadequate. The patient was operated in the Ist Surgery Clinic and a total thyroidectomy was performed. A postoperative bleeding was successfully solved.

The pathological examination described on a background of colloid goiter a multi-

centric papillary carcinoma with psammomas infiltrating the thyroid, without extension beyond the thyroid capsule. The tumor presented solid or cribriform areas and morula formation. Papillary cancer areas were found in the controlateral lobe (fig. 5 a, b). Immunostaining for $HBME_1$ was positive in 75% of tumor cells in their luminal pole, without basolateral membrane staining (fig. 5 c). 25% of cells of the cribriform and solid areas were also positive for $HBME_1$. The immunistaining with bcl_2 was positive in 100% of tumor cells (fig. 5 d). Histopathological staging of the disease was pT3Nx-G1. The pathologist conclusion was that the aforementioned characteristics are those familial forms of papillary thyroid carcinoma.

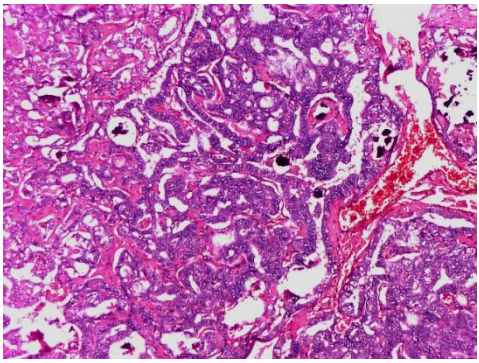

Fig. 5 a. Case 2. Papillary thyroid cancer with cribriform. Morullar pattern and a few psammomas

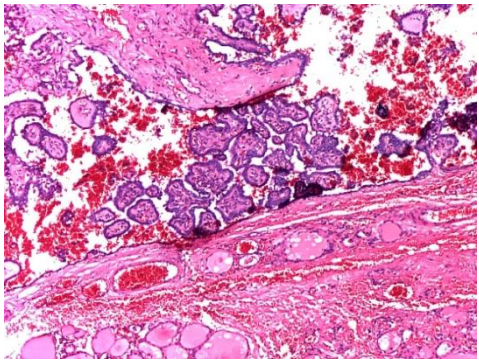

Fig. 5b. Case 2 Papillary cancer in the controlateral lobe

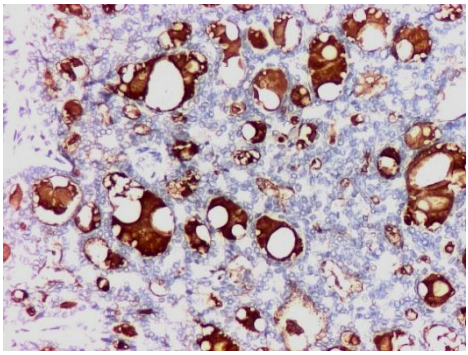

Fig. 5 c. Case 2. HBME1 immunostaining positive only in the luminal pole of tumor cells without basolateral staining

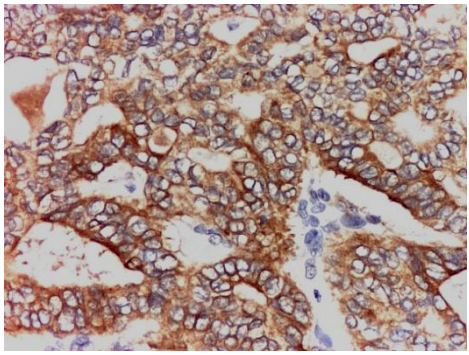

Fig. 5d. Case 2. Intense positive membrane immunostaining of tumor cells for bcl_2

The patient received a radioiodine dose of 70 mCI for ablation. Before ablation his hormonal profile showed: TSH=66.8 µIU/ml, thyroglobulin=16.5 ng/ml and antithyroglobulin antibodies: 22 IU/ml. Post ablation scan detected radioiodine uptake in the thyroid bed. After radioiodine ablation the patient receives suppressive

therapy with 150 µg of T_4. The colonoscopy performed two month showed that patient had no colonic polyposis. Careful ultrasound neck examination of his sister revealed no thyroid abnormalities.

DISCUSSION

In our knowledge, this is the first case of familial nonmedullary thyroid carcinoma (papillary carcinoma) reported in our setting. The reported cases have some typical features of FAP-associated papillary thyroid carcinoma and some particular characteristics. The proband case seemed to have an attenuated form of FAP (AFAP) with late onset of the disease and only a few polyps, proximally situation of polyps and infrequent rectal involvement as this form was defined by Half E. et al (6). The course of thyroid cancer in the proband was indolent for a very long time as mentioned for FAP-associated PTC by Cetta (16) and Ito (19), but suddenly it turned into an aggressive form with local invasion, lymph node metastases and distant lung and liver metastases as seen in the non syndromic FPTC (2, 20).

The typical histology of cribriform, morular variant of PTC, multicentricity and bilateralism (2, 15, 16) were seen in the second case. The tumor lost the affinity for HBME1 and preserves its immunostaining with bcl_2. After Nasr (21), only luminal staining for HBME1 without basolateral staining is considered to be negative for HBME1 immunostaining. These features along with presence of AFAP and papillary carcinoma in the father raise the possibility that thyroid cancer could occur before adenomatous polyposis in this particular case.

The occurrence of the disease in males (father and son) could be also considered particular features because FAP-associated thyroid cancer occurs especially or almost exclusively in women at younger age (12).

The phenomenon of "genetic anticipation" defined as "occurrence of a genetic disease at progressively younger age and with increase aggressiveness in successive generations" described by Mc Innis (1996, quoted 22) for pure, nonsyndromic familial thyroid carcinoma was seen in the second reported case. Although after a long indolent course, the diagnosis a thyroid cancer was made at the age of 68 in the father and at the age of 40 in the son.

The most important point was in our cases the earlier detection of thyroid cancer in the son, allowing an adequate management of the disease and an expected good prognosis.

CONCLUSIONS

The occurrence of a simultaneous thyroid cancer in a patient with adenomatous polyposis must be suspected at the time of diagnosis of colonic disease.

Immediate screening for thyroid cancer must be performed in all first-degree relatives of patients with FAP by neck ultrasound and FNB if possible, allowing an earlier detection and a better prognosis of the thyroid disease.

MICROSCOPIC COLITIS AND SMALL INTESTINAL BACTERIAL OVERGROWTH – DIAGNOSIS BEHIND THE IRRITABLE BOWEL SYNDROME? (Abstract): Some patients previously diagnosed with irritable bowel syndrome (IBS) may develop microscopic colitis or small intestinal bacterial overgrowth (SIBO). **Aim:** To estimate the prevalence of microscopic colitis and SIBO in patients with IBS, to evaluate the symptoms and the efficacy of treatment. **Material and methods:** We examined patients with IBS admitted in our clinic during a three-year period. We identified patients with microscopic colitis by performing total colonoscopy with multiple biopsies from normal intestinal mucosa and those with SIBO by performing a H_2-breath test with glucose. We compared the symptoms and the effectiveness of the treatment. **Results:** Out of the 132 patients initially diagnosed with IBS 3% (n=4) had microscopic colitis and 43.9% (n=58) had SIBO. Diarrhea was the main symptom in patients with microscopic colitis and SIBO (p=0.041), while abdominal pain, abdominal bloating and flatulence were prominent in IBS patients (p=0.042; p=0.039; p=0.048). Specific treatment with rifaximin in SIBO patients negativated H_2-breath test in 70.9% cases. **Conclusions:** Patients suspected to have irritable bowel syndrome should be evaluated for microscopic colitis and SIBO. The proper diagnosis and the specific treatment may cure some difficult cases of the so called "irritable bowel syndrome". **Key words:** irritable bowel syndrome, microscopic colitis, collagenous colitis, lymphocitic colitis, small intestinal bacterial overgrowth.

With prevalence between 2.5 and 22% worldwide, irritable bowel syndrome (IBS) is a chronic functional gastrointestinal disorder with heterogenous clinical manifestations and no pathognomonic features. Differentiation of IBS from other diseases may be sometimes difficult, especially when colonoscopy looks totally normal (1, 2, 3).

Microscopic colitis (MC) became a frequent diagnosis in the last years. The symptoms are similar to the IBS ones. The mucosa appears normal during colonoscopy, but multiple biopsies are required for a diagnosis that depends on well-defined histological criteria (4, 5, 6, 7, 8).

Another disease similar in clinical manifestations with IBS is small intestinal bacterial overgrowth (SIBO). It is characterized by an increased number (≥105 CFU/mL) and/or abnormal type of bacteria in the small

bowel. The gold standard for diagnosis is the microbial culture of jejunal aspirates, but because of its invasivity H2-breath tests are currently the most important diagnostic methods in SIBO, even if their accuracy is not so high (9, 10, 11, 12).

Our study is therefore aimed to estimate the prevalence of microscopic colitis and SIBO in patients diagnosed with IBS according to Rome III criteria and to compare clinical and epidemiological features of the patients in the three groups. We have also evaluated the effectiveness of treatment with rifaximin in patients diagnosed with SIBO.

MATERIAL AND METHODS

We included in our prospective study patients with a prior diagnosis of IBS, admitted in our clinic between April 2007 and April 2010. The diagnosis of IBS was confirmed on the basis of Rome III criteria and colonoscopy was performed. Prior to inclusion in the study all participants signed an informed consent form. Our study had the approval of Elias Hospital Ethics Committee.

Based on abnormal laboratory tests and colonoscopy some patients were excluded from the study. We insisted on the history of drug consumption and the presence of an acute episode of gastroenteritis before the onset of IBS-related symptoms. Clinical evaluation form registered data about the prominent symptoms, time between the onset of symptoms and the diagnosis of IBS, MC and SIBO and the treatment applied.

During colonoscopy at least four biopsies of normal mucosa from different regions of the colon were taken. Minimal macroscopic lesions (erythema, edema or superficial ulcers of mucosa) were noticed. Characteristic histopathological changes for collagenous colitis were: subepithelial collagenous band thickening > 10 μm, increased number of inflammatory cells in lamina propria, increased intraepithelial lymphocytes and possible surface epithelial damage. Lymphocytic colitis was defined by > 20 intraepithelial lymphocytes/100 epithelial cells and an increased number of inflammatory cells in the lamina propria, associated with normal collagen band. Superficial epithelial injuries were also identified.

All patients in the study group underwent glucose breath test in order to detect SIBO. We measured H_2 in expired air before and after ingestion of 50 g of glucose dissolved in 250 ml water. Measurements were performed every 15 minutes for 120 minutes; the test was positive if one value of expired H_2 exceeded 10-12 ppm over baseline. In patients with positive glucose breath test rifaximin was administered at the daily dose of 1200 mg for 7 days and the test was repeated after two weeks. Simultaneous with the second test patients completed a new clinical form.

We noticed the following: the criteria for MC and/or SIBO in patients with IBS, the demographic features of the patients, the main clinical manifestations, the possible association of autoimmune diseases and drugs in microscopic colitis patients, the period of time between the onset of symptoms and the diagnosis of IBS, MC and SIBO and the outcome after treatment.

Demographic and clinical characteristics of patients in the study group were compared statistically by Student-t test for quantitative variables and χ^2 test for qualitative variables. Statistical hypothesis testing was performed by calculating the value of p ($p < 0.05$ considered statistically significant) and 95% confidence interval. Data were statistically analyzed using *SPPS*

version 17.0 software.

RESULTS

Figure 1 summarizes the general methodology and the results of our study.

We confirmed the diagnosis of IBS based on Rome III criteria in 132 patients. Depending on their predominant transit disorder they were classified into three types of IBS: with diarrhea (39.4%), with constipation (23.5%) and with mixed bowel changes (37.1%).

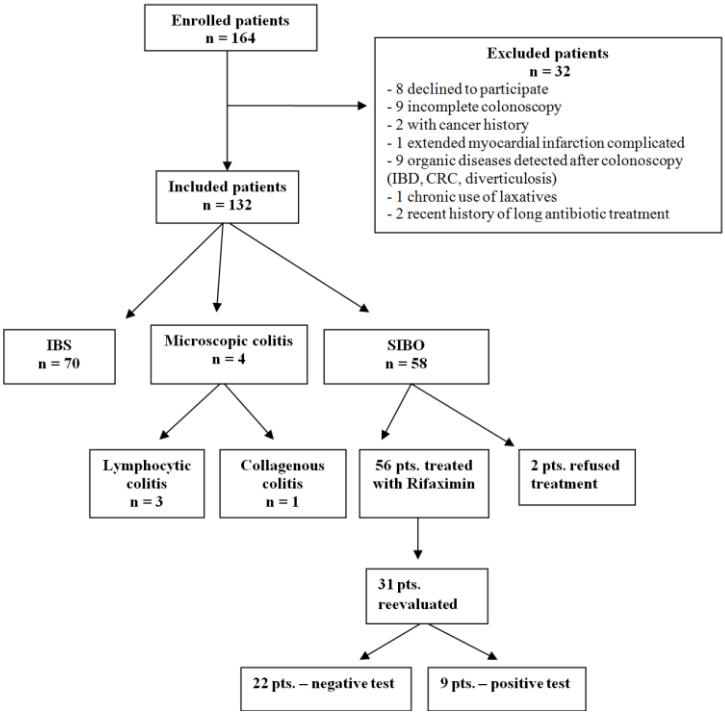

Fig. 1. Methodology and study results

The average age of patients in our study group was 46.2 ± 15.2 years, and there was a predominance of women (59.1%). In 12 patients (9.1%) we identified a history of an acute gastroenteritis. The most frequent symptoms were transit disorders (diarrhea or alternating diarrhea/constipation), bloating, flatulence and abdominal pain. Blood tests (including thyroidian hormones, antinuclear antibodies and rheumatoid factor), abdominal ultrasound and microbiological stool examination were normal in all patients. Fecal calprotectin test was positive in 15 cases (11.4%).

All 132 patients underwent lower gastrointestinal endoscopy, which detected minimal colonic mucosal changes in 10 patients (7.6%). Following detailed histopathological examination of normal mucosa biopsies, microscopic colitis was found in only four patients. The main clinical and biological characteristics of patients with

MC are listed in table I.

Based on positive results on breath test we confirmed the presence of SIBO in 58 patients (43.9%): 67.2% women and 32.8% men. The mean age was 42.5 ± 14.8 years. The most common symptoms were diarrhea and bloating, as well as in patients with IBS. Positive fecal calprotectin test was observed in only 13.8% patients.

56 patients with SIBO received rifaximin at the daily dose of 1200 mg for 7 days. Only 31 patients (55.3%) came to repeat the test after 2 weeks. In retested patients, negativity was achieved in 70.9%. For the 9 patients with positive second test a new cycle of rifaximin was prescribed and 3 patients had a negative breath test after two weeks. There were no side effects during treatment and obtaining negative breath test was followed by partial or total remission of symptoms in all patients.

TABLE I

Characteristics of patients with MC

Age/ sex	MC type	Smoker	Celiac disease	NSAIDs	PPI	Diarrhea/ nocturnal	Weight loss	Period of symptoms	Calprotectin	Normal mucosa
46/ F	LC	Yes	Yes	No	No	Yes/ no	No	2 years	Yes	Yes
58/ F	CC	Yes	No	No	No	Yes/ yes	No	6 years	Yes	Yes
65/ M	LC	No	No	No	Yes	Yes/ yes	Yes	5 months	Yes	Yes
72/ F	LC	No	No	Yes	No	Yes/ yes	Yes	7 weeks	Yes	Yes

Correlating the type of the disease with symptoms we found that diarrhea and nocturnal diarrhea were common manifestations in patients with SIBO (p=0.041) and abdominal pain was more frequent in patients with IBS (p=0.042). The following were also more common in patients with IBS: abdominal bloating (p=0.039) and flatulence (p=0.048). For other symptoms we obtained no statistically significant values (fig. 2).

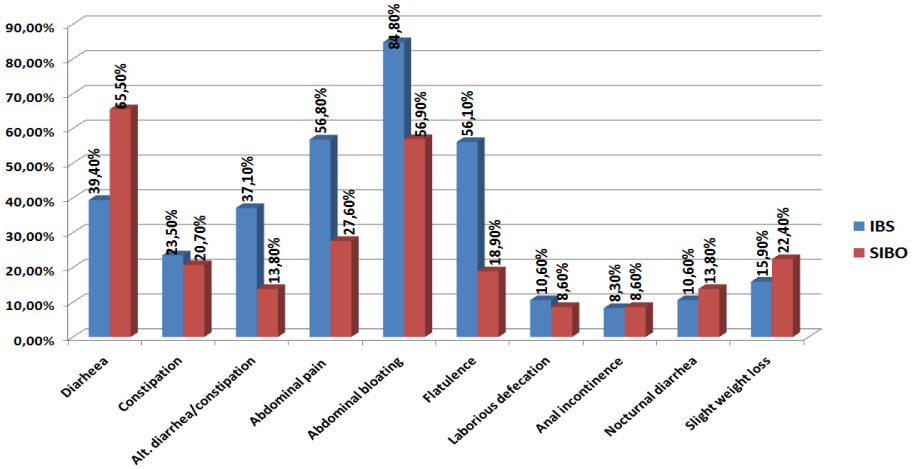

Fig. 2. Comparison of symptoms in patients with IBS and SIBO

DISCUSSION

An increasing number of papers in the literature claim that a diagnosis of IBS could hide some other entities. After successful exclusion of the most frequent causes of chronic diarrhea or persistent constipation a number of rarely identified diseases can mimic IBS. Two of them have drawn our attention: microscopic colitis and SIBO.

Microscopic colitis has become a more frequent diagnosis in the last years due to increasing awareness of physicians as well as to a greater accuracy of diagnostic methods. A study performed in Sweden on 1018 patients identified microscopic colitis in 10% of the patients who underwent colonoscopy for chronic watery non-bloody diarrhea, the percentage increasing to 20% when only patients above the age of 70 were considered (7). Another study on 30 patients previously diagnosed as having IBS reported an incidence of lymphocytic colitis of 23.5%, while other authors found among diarrhea-IBS patients an incidence for collagenic colitis of 7.2% and for lymphocytic colitis of only 2.2% (13, 14). In our group the frequency of MC was lower: 3% of the total of IBS patients and 7.7% of the diarrhea-IBS. Due to the small number of microscopic colitis, statistical interpretation was not possible, but the symptoms were similar to those described by other studies (14, 15).

An association between MC and the use of specific drugs was reported, especially NSAIDs (up to 34%), proton pump inhibitors (Lansoprazole) and ticlopidine (14, 15, 16). Of our four patients with MC, one was treated with NSAIDs and one with Lansoprazole before the onset of diarrhea, which led us to consider these drugs as causative. The association between MC and other autoimmune diseases is seen up to 40% of cases, the most frequent being rheumatoid arthritis, celiac disease, tiroiditis and diabetes. We identified in our group a single case of celiac disease in a patient with lymphocitic colitis.

Budesonide appears to be the optimal drug choice for treating microscopic colitis nowadays. Despite this fact, only one patient in our study had to be treated with budesonide, the other three improved on symptomatic treatment (loperamide).

SIBO can be identified in 45-50% of IBS patients, partly explaining the symptoms (12, 17, 18, 19). Based on glucose breath tests we were able to diagnose SIBO in 43.9% of IBS patients. The major part (65.5%) was experiencing diarrhea, while fewer experienced chronic constipation (20.7%) or mixed transit disturbances (13.8%). The second frequent complain in our group of SIBO patients was bloating (56.9%), a symptom that most authors regard as the most specific sign of alterations in the intestinal flora (12).

One week of rifaximin 1200 mg/day has led to negative results of the glucose hydrogen breath test in 70.9% of cases. Our data confirm the results of other studies which showed a positive response between 59.4% and 82.6% for SIBO patients treated with rifaximin, with or without subsequent treatment with probiotics. Repeated courses of rifaximin in initial non-responders has led to a favourable outcome in 33.3% of cases, a better response than the ones obtained with ciprofloxacin, norfloxacin, amoxicillin - clavulanate, gentamicin, cotrimoxazole, polymyxins or tetracyclin (12, 18, 19).

Symptoms in IBS, MC and SIBO pa-

tients show some degree of overlap, but also a few significant differences. Most patients experiencing diarrhea (80.76%) and especially those with nocturnal diarrhea (78.57%) have been diagnosed with MC or SIBO. Abdominal pain, bloating and flatulence were described more frequently in patients with IBS and less in MC or SIBO patients. In what calprotectin is concerned, we found positive tests more frequently in MC and SIBO (80%) and only a smaller proportion in IBS patients.

CONCLUSIONS

We can conclude that, in order to correctly identify MC or SIBO, patients presenting as IBS should undergo an initial evaluation including colonoscopy with multiple level biopsies from normal-appearing mucosa and a glucose or lactulose hydrogen breath test. The symptoms of the three described conditions are very similar. Nocturnal diarrhea and a positive stool test for calprotectin can help differentiating MC and SIBO patients from those suffering from IBS, but their specificity is far from 100%. Specific management with budesonide in MC and with rifaximin in SIBO leads to significant clinical improvement and a favorable response in difficult to treat cases of „irritable bowel syndrome".

EXTRACELLULAR MATRIX ADMINISTRATION AS A POTENTIAL THERAPEUTIC STRATEGY FOR PERIODONTAL LIGAMENT REGENERATION

The current strategies employed for the treatment of connective tissue disease include the application of stem cells, the use of functional molecules that can reorganize tissue integrity and cellular activities to recover connective tissue function. Approaches to the regeneration of periodontal tissue, which is the tooth-supporting connective tissue, have made some progress recently and provide a useful experimental model for the evaluation of future strategies to treat connective tissue diseases such as periodontal disease. The ultimate goal of periodontal tissue regeneration is to reconstruct the ligament structure that will sustain the required mechanical force to connect with mineralized tissues such as cementum and alveolar bone. The administration of extracellular matrix could be used as an additional therapeutic strategy to stem cell transplantation and cytokine administration in periodontal tissue regeneration therapy. Although various available tissue engineering technologies can now achieve periodontal tissue regeneration, extracellular matrix administration therapy is likely to play an essential future role in the development and regeneration of periodontal tissue and attenuate the signaling events that mediate tissue degradation. Hence, extracellular matrix administration could serve as a novel technology in periodontal tissue regeneration and also as a viable approach to alleviating connective tissue disorders such as Marfan's syndrome [Saito M, Tsuji T. Extracellular matrix administration as a potential therapeutic strategy for periodontal ligament regeneration. Expert Opin Biol Ther. 2012 Mar;12(3):299-309].

IDENTIFICATION OF BONE MASS AND BONE *TURNOVER* IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH CORTICOSTEROIDS IN ORDER TO ELABORATE AN OPTIMAL THERAPEUTIC ATTITUDE (**Abstract**). Corticosteroids (CS) are currently used in Rheumatoid Arthritis (RA) in conjunction with either synthetic remissive or biologic drugs. **Aim**: In our study we used have focused on bone mineral density assessment (BMD) in RA patients with and without low doses of CS in order to elaborate an optimal therapeutic approach. **Material and methods**: prospective observational study on 55 consecutive patients with RA (1987, ACR diagnostic criteria) classified in two groups based on CS use: group A - 23 RA receiving CS and subgroup B – 32 RA without CS. All patients have been evaluated according to a predefined protocol including demographics, clinical, biological and therapeutic RA characteristics, BMD and T-score assessment by DXA (Hologique QDR) (1994, WHO classification). Subgroup analysis was done in SPSS-12 software, $p<0.05$. **Results**: No significant differences in demographics and RA related parameters ($p>0.05$) have been demonstrated between subgroups. However, significant changes in BMD and T-score have been reported in RA receiving CS as follows ($p<0.05$): up to 74% cases with osteoporosis, 13% with fracture and 8.7% with osteopenia (A) *versus* 31.3% with osteoporosis, 28.1% with fracture and 15.6% with osteopenia (B). Moreover, 90% of RA under 7.5 mg CS daily and all receiving >10mg daily presented with osteoporosis; also, osteoporosis has been demonstrated all postmenopausal RA in group A (75%) and only 68% of group B (76%). **Conclusions**: concomitant CS use in RA, even low doses, is commonly associated with low BMD, irrespective of other risk factors. **Key words**: BONE MASS, BONE *TURNOVER*, RHEUMATOID ARTHRITIS, CORTICO-STEROIDS

Poliartrita reumatoidă (PR), reumatismul inflamator cu largă frecvență, afectează aproximativ 1% din populația generală, fiind recunoscută ca o boală severă, autoîntreținută şi progresivă, care induce leziuni osteo-articulare, cu deficit funcțional şi pierderea capacității de muncă, cu o mortalitate prematură considerabilă, reducând semnificativ speranța de viață a bolnavilor cu această afecțiune (1, 2, 3).

În patogenia PR este greu de definit o succesiune riguroasă a evenimentelor, de-

oarece celulele şi sistemele biologice umorale acţionează complex, simultan şi au un mare grad de interdependenţă. Ele se desfăşoară în două planuri, în structura sinovialei şi în cavitatea articulară, între cele două compartimente existând multiple influenţe reciproce (4). Se poate aprecia că celulele oferă suportul evoluţiei cronice progresive, pe când elementele umorale sunt responsabile de inflamaţia acută.

Între manifestările extra-articulare ale PR se include şi osteoporoza, dar mecanismele patogenice sunt multiple, constelaţia citokinică proinflamatorie caracteristică bolii şi corticosteroizii cu impact asupra densităţii minerale osoase (DMO) şi *turnover*-ului osos fiind elemente definitorii (5,6,7). Cercetări recente au adus în atenţie evoluţia DMO raportat la durata şi tipul tratamentului, precum şi modalitatea evolutivă a bolii sub aspectul necesităţii instituirii cât mai precoce a unui tratament remineralizant (6,8,9,10), incluzând o dietă bogată în calciu, exerciţiile fizice, precum şi administrarea zilnică a 1000 mg calciu şi vitamina D 800 UI încă de la începutul corticoterapiei, iar la o lună după iniţierea acesteia, se dozează calciul urinar care, dacă depăşeşte 300 mg / 24 h, va necesita asocierea unei tiazide şi corectarea dozei de calciu şi vitamina D (11). În cazul în care DMO indică o scădere a acesteia, se instituie tratament corespunzător, în care un loc important îl ocupă bisfosfonaţii (12). Dintre bisfosfonaţii utilizaţi în practică, acidul alendronic, 70 mg /săptămână (Fosamax, Fosavance), acidul risendronic (Actonel 35 mg/săptămână), acidul ibandronic (Bonviva 150 mg /lună), au determinat o creştere a densităţii minerale osoase (13). Un rol important îl are şi terapia de substituţie hormonală (la femei, cu preparate de estrogen cu sau fără progesteron, iar la bărbaţi, cu testosteron) (14).

Datele acumulate au fost evaluate cu ajutorul programelor MS EXCEL şi SPSS 13.0, folosind intervalele de încredere la pragul de semnificaţie 95%, iar pentru testarea diferenţelor s-au utilizat testele χ^2 , t-Student, p.

Studiul si-a propus identificarea modificărilor masei şi *turnover*-ului osos la pacienţii cu PR trataţi cu corticosteroizi, în scopul elaborării unei atitudini terapeutice optime, având in atenţie: evaluarea modificărilor densităţii minerale osoase, identificarea particularităţilor etiologice, evaluarea modificării metabolismului mineral osos, identificarea mecanismelor patogenice implicate în degradarea masei şi *turnover*-ului osos, dinamica modificărilor masei şi *turnover*-ului osos induse de excesul de cortizon, investigarea modificărilor masei şi *turnover*-ului osos drept consecinţă a diferitelor intervenţii terapeutice.

MATERIAL ŞI METODE

În perioada 2010-2011, în Clinica de Reumatologie a Spitalului Clinic de Recuperare Iaşi, au fost studiaţi 55 pacienţi cu diagnosticul de PR (criteriile de diagnostic ACR, 1987), în ordinea prezentării în clinică. Aceştia au fost împărţiţi în două loturi, în vederea unui studiu comparativ: *lotul A,* alcătuit din 23 pacienţi (41.82 %) cărora, în cursul evoluţiei bolii, li s-a administrat tratament cu corticosteroizi (CS) şi *lotul B,* martor, alcătuit din 32 pacienţi (58.18%) care nu au luat niciodată tratament cu CS.

Datele asupra pacienţilor au fost obţinute pe baza unei fişe standard ce a urmărit evaluarea unor particularităţi demografice, clinico-biologice şi terapeutice legate de PR, precum şi determinarea densităţii minerale osoase prin absorbţiometrie duală cu raze X (*Dual X-Ray Absorbtiometry,* DXA)

folosind aparatul Hologique QDR cu raze X, care măsoară densitatea minerală osoasă, exprimând cantitatea de os pe unitatea de suprafață sau volum (fig. 1 A, B, C).

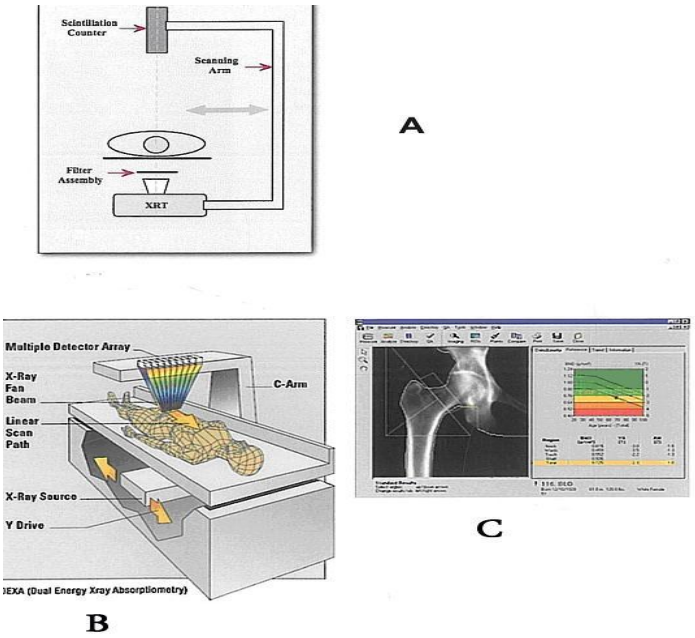

Fig. 1. A+ B - Diagrama aparatului de scanare DXA; C- Fişă de osteodensitometrie (15)

Criteriile Organizației Mondiale a Sănătății (OMS) din 1994 folosesc scorul T pentru delimitarea categoriilor diagnostice în osteoporoză. Astfel:

- scorul T > - 1 deviație standard (DS) definește populația cu masă osoasă normală;
- scorul T între -1 DS şi – 2.5 DS reprezintă criteriul pentru diagnosticul de osteopenie;
- scorul T ≤ - 2.5 DS este criteriul de diagnostic pentru osteoporoză;
- scorul T ≤ - 2.5 DS şi prezența unei fracturi de fragilitate reprezintă criteriul pentru diagnosticul de osteoporoză severă (manifestă).

Studiul s-a desfăşurat cu aprobarea comisiei de etică; toți pacienții au semnat un consimțământ informat înaintea includerii în studiu.

REZULTATE ŞI DISCUȚII

Aspecte epidemiologice. *Sexul.* Pacienții incluși în lotul A au fost 87% femei şi 13% bărbați, în timp ce în lotul B proporția a fost de 79% femei şi 21% bărbați. Statistic s-a demonstrat că structura pe sex a fost omogenă în cele două loturi (χ^2=0.23; GL=1; p=0.629), cu raportul cotelor de 1.87 (OR=1.87; IC95%: 0.36÷10.60).

Vârsta. Repartiția pe grupuri de vârstă a loturilor studiate a arătat o incidență crescută a PR începând cu decada a patra de viață, dar o frecvență mult mai mare fiind raportată în cea a cincea şi a şasea decadă. Distribuția pe grupuri de vârstă s-a dovedit a fi, de asemenea, omogenă (χ^2=3.45; GL=5; p=0.631). Ponderea pacienților cu

PR în vârstă de peste 40 de ani, a fost de 87% în lotul A şi 81% în B (tab. I).

TABELUL I

Repartiţia pe grupuri de vârstă a celor două loturi

Vârsta la momentul studiului (ani)	Nr.pacienţi/lot	
	A	B
<30	0	1
30-39	3	5
40-49	7	7
50-59	9	9
60-69	4	8
≥70	0	2

Aspecte clinice.

Redoarea matinală a fost mai intensă la pacienţii din grupul A, comparativ cu B (t=4.45, GL=53, p<0.001): 90± 20 minute, faţă de 60±30 minute (fig. 2).

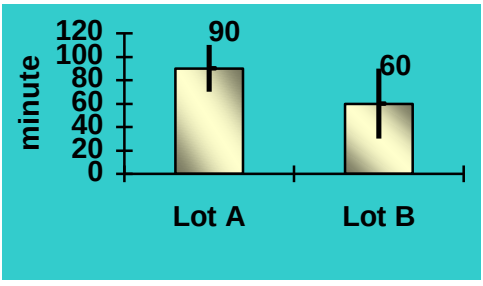

Fig. 2. Durata redorii matinale

În ceea ce priveşte *durata de evoluţie* a PR, s-a constatat la pacienţii din lotul A o medie de 9±6 ani, uşor mai crescută decât media evoluţiei bolii la cei din lotul martor (7± 3 ani), fără diferenţă semnificativ statistic (t=1.47, GL=53, p>0,05) (fig. 3).

Osteoporoza din PR impune o abordare diferenţiată, pe de o parte ca un fenomen atribuibil citokinelor proinflamatorii aferente patogeniei, a modificărilor metabolice (ale calciului) şi a hormonilor circulanţi, pe de altă parte, ca un efect bine cunoscut al corticoterapiei. Invariabil însă, osteoporoza reprezintă un element cvasiconstant întâlnit la pacienţii cu PR, dar un rol important în ceea ce priveşte evoluţia îl are riscul de fractură, în special cele vertebrale şi ale şoldului, indicând nivelul morbidităţii şi al mortalităţii, cu o scădere semnificativă a calităţii vieţii (8,9,10).

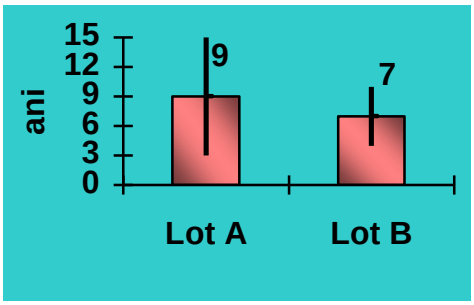

Fig. 3. Durata de evoluţie a poliartritei reumatoide

Două cazuri aparţinând lotului A, care au primit tratament CS, au prezentat fractură (8.7%), pe când în lotul B doar una (3.1%), distribuţia de frecvenţe nefiind semnificativ statistică (χ^2=0.09; GL=1; p=0.768).

Aspecte paraclinice. Examenele de laborator au vizat sindromul inflamator (*VSH*, proteina C reactivă-*CRP)* şi sindromul disimunitar (reacţia Latex şi Waaler-Rose pentru determinarea factorului reumatoid-*FR*).

Probele efectuate au arătat că sindromul inflamator este intens prezent la majoritatea pacienţilor studiaţi, atestând riscul de boală moderată sau severă, cu potenţial distructiv important şi predispoziţie la invaliditate prin apariţia deformărilor articulare(1,3)

VSH-ul, marker al gradului inflamaţiei reumatoide, a prezentat valori pentru lotul A: 20 - 40 mm/oră (3 cazuri), 40 - 60

mm/oră (5 cazuri), 60 - 80 mm/oră (10 cazuri), şi > 80 mm/oră (5 cazuri). Comparativ, în lotul B valorile *VSH*-ului au fost: 20-40 mm/oră (3 cazuri), 40-60 (12 cazuri), 60 - 80 mm/oră (9 cazuri) şi > 80 mm/oră (8 cazuri). În stadiul funcțional III şi IV valorile medii au fost dominante.

Inflamația şi caracterul eroziv al PR sunt traduse prin prezența *CRP*, care a fost înregistrată la 80% din cazuri în lotul A şi 60% în B, distribuția de frecvență fiind semnificativă statistic (χ^2=4.94; GL=1; p=0.026).

A fost determinat *FR* (explorare de rutină în PR), constituind unul din criteriile de diagnostic, iar titrurile serice înalte atrag atenția asupra unei evoluții severe, articulare şi extraarticulare. În 88% din cazurile care au beneficiat de corticoterapie, a fost evidențiată prezența FR şi doar în 60% din cele fără tratament, orientând decizia urmăririi pacienților tratați cu prednison (χ^2=18.94; GL=1; p=0.00001).

Aspecte terapeutice. În arsenalul terapeutic al PR evaluate s-a inclus: terapia patogenică remisivă în 76% cazuri; antiinflamatoarele non-steroidiene (AINS) în 96%; corticoterapia în 52% cazuri. În funcție de doza de CS indicată, două cazuri au primit doze între 5 şi 7.5 mg/zi, patru pacienți doze mai mari de 10 mg/z ; majoritatea (17 : 30,9 %) încadrându-se însă în doza zilnică de 7.5-10 mg.

Examenul densitometric. Osteodensitometria dual cu raze X este o metodă radiologică de măsurare a masei osoase, examinare unică, standardizată, acceptată de OMS pentru determinarea gradului de osteoporoză.(6). Diagnosticul de osteoporoză este stabilit la 15-20% din femeile aflate în postmenopauză prin aplicarea DXA la nivelul coloanei sau şoldului şi folosirea unui prag de diagnostic de -2.5DS. Incidența osteoporozei creşte exponențial după vârsta de 50 de ani, ca urmare a scăderii liniare cu vârsta a densității minerale osoase si distribuția gaussiană a valorilor DMO. Măsurarea DMO s-a realizat la toți pacienții studiați (tab. II).

TABELUL II

Structura loturilor în relație cu valorile scorului T

Scorul T	Diagnostic	Lotul A	Lotul B
> -1 DS	Normal	1	8
-1 DS - (-2.5 DS)	Osteopenie	2	5
≤-2.5 DS	Osteoporoză	17	10
≤ -2.5 DS + fractură	Osteoporoză severă	3	9

Statistic au fost evidențiate semnificativ mai multe cazuri de osteoporoză în lotul A (73.9%) comparativ cu B (31.3%), iar la lotul B s-a remarcat existența a 25% cazuri ameliorate, în timp ce la lotul A frecvența acestora a fost de numai 4.3% (χ^2=10.35; GL=1; p=0.016) (fig. 4, 5).

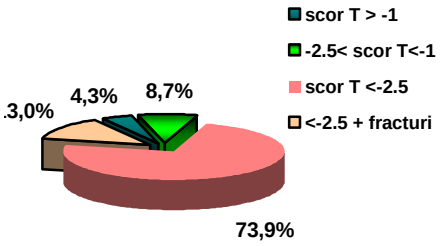

Fig. 4. Frecvența osteoporozei în lotul A

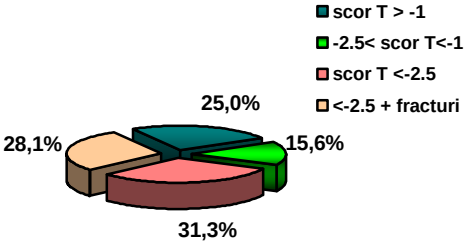

Fig. 5. Frecvența osteoporozei în lotul B

După iniţierea terapiei cu CS s-a constatat o fază rapidă de pierdere a masei osoase (primul an de tratament), urmată de o reducere mai lentă, dar continuă, a DMO, iar apariţia osteoporozei a fost corelată şi cu doza zilnică de prednison.

Cei doi pacienţi care au primit mai puţin de 7.5 mg pe zi nu au dezvoltat osteoporoză, în timp ce frecvenţa osteoporozei a fost depistată la 90% din pacienţii cu doze de 7.5-10 mg şi de 100 % la cei cu doză > 10 mg/zi (tab. III).

TABELUL III

Frecvenţa osteoporozei în relaţie cu doza de prednison

Doza de prednison	Total pacienţi	Pacienţi cu osteoporoză	%
5-7.5 mg/zi	2	0	0
7.5-10 mg/zi	17	15	90
> 10 mg/zi	14	14	100

Pentru valorile mai mici de 10, proporţiile sunt orientative S-a remarcat prezenţa osteoporozei la 31% dintre pacienţii ce nu au urmat tratament cu prednison, situaţie posibil a fi explicată de intervenţia şi a altor factori de risc (vârsta, menopauza, sedentarismul prelungit datorat bolii şi alimentaţia carenţială).

Repartiţia osteoporozei pe grupuri de vârstă la pacienţii în studiu a evidenţiat prevalenţa cea mai crescută pentru intervalul 40-69 ani (tab. IV).

Un alt factor de risc important în apariţia osteoporozei este menopauza, deoarece estrogenii modifică homeostazia calciului seric prin influenţa lor asupra glandei paratiroide sau a ţesuturilor ţintă pe care acţionează şi PTH. Repartiţia pacientelor cu osteoporoză în relaţie cu prezenţa menopauzei în cele două loturi studiate a evidenţiat că în lotul A, dintre cele 20 femei, 15 (75%) erau în etapa de postmenopauză, toate fiind diagnosticate cu osteoporoză; în lotulB, din 25,19 (76%) erau în post-menopauză dar doar 17 (68%) au fost diagnosticate cu osteoporoză.

TABELUL IV

Repartiţia bolnavilor cu osteoporoză pe grupuri de vârstă

Grupurile de vârsta (ani)	Lotul A		Lotul B	
	Număr pacienţi	Cazuri cu osteoporoză	Număr pacienţi	Cazuri cu osteoporoză
< 30	0	0	1	0
30-39	3	1	5	0
40-49	7	5	7	1
50-59	9	8	9	4
60-69	4	4	8	3
≥ 70	0	0	2	1

S-a dovedit că deficitul hormonal înregistrat la menopauză induce apariţia osteoporozei, aspect evidenţiat în ambele loturi de studiu (χ^2=0.32; GL=1; p=0.574).

Cercetările au dovedit prezenţa osteoporozei la 74% dintre pacienţii ce au beneficiat de tratament cu CS faţă de doar 31% la cei din lotul martor, dovedind efectele negative ale CS asupra metabolismului osos, accentuând resorbţia osoasă şi, în acelaşi timp, reducând procesul formării osului, având drept consecinţă reducerea masei osoase şi creşterea riscului de fractură.

CONCLUZII

1. Osteodensitometria este o metodă de diagnostic paraclinic ce trebuie obligatoriu aplicată pe parcursul evoluţiei bolii

pentru a surprinde modificările DMO şi pentru a interveni terapeutic corespunzător. Cu ajutorul osteodensitometriei a fost evidențiată prezența osteoporozei induse de CS la circa trei pătrimi dintre pacienții cu PR studiați.

2. Prin intermediul osteodensitometriei s-a constatat că în primele 6 luni de tratament cu prednison modificările la nivelul țesutului osos sunt de tip osteopenie, până la un an valorile indică osteopenie la limită cu osteoporoza, iar peste un an se instalează osteoporoza.

3. S-a dovedit că osteodensitometria are un rol major în evidențierea riscului de apariție a osteoporozei cortizonice, contribuind astfel la decizia instituirii unui tratament prevențional. Doza de prednison influențează apariția osteoporozei; dozele de 7.5 mg⁄zi administrate cronic pot determina osteoporoză în 90% din cazuri.

4. La începerea corticoterapiei s-a impus înlăturarea factorilor cu risc adiționali corectabili, cu obținerea cooperării informate a pacientului.

Suplimentarea cu calciu şi vitamina D a fost necesară la toți bolnavii incluşi în studiu care necesitau corticoterapie pe termen lung, din cauza balanței calcice negative induse de tratamentul cu CS.

SURGICAL TREATMENT OF TARSAL TUNNEL SYNDROME IN DIABETIC NEUROPATHY (Abstract): Posterior tibial nerve decompression surgery in tarsal tunnel syndrome in patients with diabetic neuropathy reduces pain, improves sensitivity and prevents foot ulcers and lower leg amputations. Aim: To observe and assess the recovery of plantar sensitivity recovery and the healing of ulcerative lessions of the foot, by clinical examination, exploration and analysis of quantitative neurosensory by surgical decompression of the tarsal tunnel. Material and methods: We evaluated a total of 10 patients and 12 symptomatic diabetic neuropathy feet in a prospective clinical study, surgically treated in the Clinic of Plastic Surgery and Reconstructive Microsurgery Iaşi, during January 2008 - June 2011, where we practiced tibial nerve decompression and neurolysis in tarsal tunnel syndrome. Results: Gender distribution of patients in the study group was predominantly male (60%), the ratio M/F = 1.5/1. Posterior tibial nerve decompression surgery resulted in recovery of plantar foot sensitivity in 90% patients in the study group. Testing Semmes-Weinstein 10 g monofilament was positive in 83.3% of the feet preoperatively whereas postoperatively only 25%, distribution of statistically significant ($\chi 2 = 6.04$, GL = 1, $p = 0.014$). Postoperative score to test a range of Riedel-Seiffer returned to normal in all patients: score 7 to 58.3% and score 8 to 41.7% of total standing tested. Conclusions: Tarsal tunnel decompression in diabetic patients with peripheric neuropathy improves plantar sensitivity, leads to healing of ulcerative plantar lesions and improves quality of life and should be performed in all patients with diabetic peripheral neuropathy in which conservative and / or medical treatment failed.
Key Words: DIABETIC NEUROPATHY, TIBIAL NERVE COMPRESSION, TARSIAN TUNNEL DECOMPRESSION

Neuropatia diabetică distală simetrică reprezintă forma cea mai comună, ocupând 75% dintre neuropatiile periferice. Pentru diagnosticul clinic al neuropatiei diabetice, 2 din cele 5 caractere sunt necesare: (i) semne, (ii) simptome, (iii) teste senzoriale cantitative, (iv) viteză de conducere nervoasă, şi (v) teste autonome (1, 2). Istoria naturală a neuropatiei diabetice este progresivă, cu pierderea sensibilității plantare care poate duce la apariția ulcerațiilor şi/sau amputațiilor (3). Studiile au arătat că decompresiunea chirurgicală a nervilor periferici de la nivelul extremităților inferioare la pacienții cu neuropatie diabetică poate reduce durerea, redobândi sensibilitatea, şi preveni ulcerațiile şi amputațiile (4, 5). În contextul acestor caracteristici ale

neuropatiei diabetice periferice, obiectivele acestui studiu au fost de a urmări şi evalua redobândirea sensibilității plantare şi vindecarea leziunilor trofice de la nivelul piciorului cu ajutorul examenului clinic, a explorărilor funcționale şi prin analiza cantitativă neurosenzorială la pacienții cu forma cea mai comună de neuropatie diabetică, şi anume polineuropatia senzorimotorie, după decompresiunea chirurgicală a canalului tarsian, într-un studiu prospectiv, la 3, 6 şi 12 luni după intervenția chirurgicală.

MATERIAL ŞI METODE

Am evaluat un număr de 10 pacienți şi 12 picioare diabetice cu neuropatie diabetică simptomatică într-un studiu clinic prospectiv, operați în Clinica de Chirurgie Plastică şi Microchirurgie Reconstructivă Iaşi pe perioada ianuarie 2008 – iunie 2011, cărora li s-a practicat decompresiunea canalului tarsian şi neuroliza nervului tibial posterior. Toți pacienții erau diagnosticați la momentul prezentării cu diabet zaharat tip 1 sau tip 2, aflați în evidența Clinicii de Diabet Nutriție şi Boli Metabolice Iaşi. Evaluarea redobândirii sensibilității plantare pre- şi postoperator a fost evaluată cu ajutorul examenului clinic în special prin urmărirea dispariției semnului Tinel, efectuarea testelor cantitative senzoriale care cuprinde testul sensibilității tegumentare cu monofilamentul Semmes-Weinstein (monofilamentul 10 g) şi evaluarea pragului de percepție a vibrațiilor cu diapazonul Riedel-Seiffer (Boehringer Mannheim GmbH).

Distribuția pe sexe a pacienților din lotul de studiu a fost preponderent masculină (60%), raportul M / F = 1,5/1. Distribuția pe grupe de vârstă relevă ponderea mare a cazurilor la grupa de vârstă 65-69 ani, cu precădere la sexul masculin. Vârsta medie a pacienților cărora li s-a practicat decompresiunea canalului tarsian şi neuroliza nervului tibial posterior, la intrarea în studiu, a fost de 61,1±6,52 ani, variind de la 51 la 69 ani.

1. **Evaluarea cantitativă senzorială**. *Testul senzorial cantitativ cu monofilamentul Semmes-Weinstein 5.07* care corespunde forței aplicate de 10 g (Baseline® tactileTM monofilament evaluator case, U.S.A.) - a fost efectuat înainte şi după decompresiunea canalului tarsian. Zonele de elecție unde se aplică monofilamentul sunt capul metatarsienelor I şi V, precum şi fața pulpară a halucelui. Monofilamentul se aplică perpendicular pe tegument şi o forță suficientă încât să se curbeze (6) (fig. 1). Sensibilitatea protectivă este prezentă dacă pacientul răspunde corect la cel puțin 2 din trei încercări. Senzația protectivă este absentă cu cel puțin 2 răspunsuri incorecte şi pacientul are un risc crescut de a dezvolta ulcerație plantară. Pierderea sensibilității protective a fost definită ca acel grad de pierdere a sensibilității care permite producerea unei leziuni tegumentare fără ca pacientul să o resimtă dureroasă (7). Sensibilitatea metodei este de 66-91%, iar specificitatea ei 34-86% (8).

2. **Evaluarea sensibilității vibratorii**. *Evaluarea pragului de percepție a vibrațiilor cu Diapazonul Riedel-Seiffer* (Boehringer Mannheim GmbH). Baza diapazonului se aplică pe proeminențe osoase, maleolele, articulația interfalangiană pe fața dorsală a halucelui, articulația metatarsofalangiană sau pe vârful halucelui (fig. 2) Valorile normale ale testului sunt cuprinse între 6/8 şi 8/8 pentru indivizii sub 60 de ani şi între 4/8 şi 8/8 pentru cei peste 60 de ani (9).

Fig. 1. Testarea sensibilității cu monofilamentul Semmes-Weinstein 5.07

Fig. 2. Aplicarea diapazonului pe suprafețe osoase

3. Descrierea tehnicii chirurgicale. Tratamentul chirurgical al decompresiunii canalului tarsian constă în practicarea unei incizii care începe la 4 cm proximal de maleola medială, urmăreşte îndeaproape partea posterioară a maleolei şi se extinde în jos către aspectul plantar al piciorului, fiind curbată anterior călcâiului. Fascia profundă este incizată, şi apoi se continuă distal cu incizia flexorului retinaculum (fig. 3).

Se secționează superficial fascia abductorului halucelui şi apoi septul dintre nervul plantar medial şi lateral (diviziunea nervului tibial în canalul tarsian) (10) (fig. 4).

Se poate efectua la nevoie pe lângă neuroliza externă şi neuroliza internă, precedată de epineurotomie longitudinală a nervului tibial posterior.

Fig. 3. Secționarea flexorului *retinaculum*

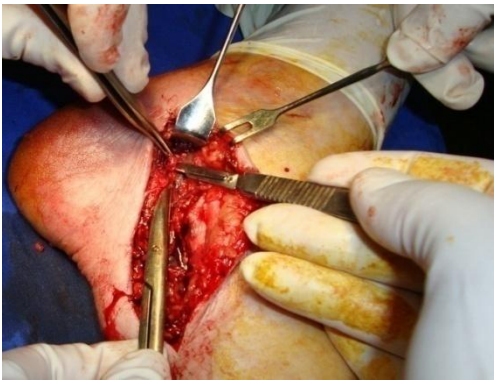

Fig. 4. Secționarea septului fibros între nervul plantar medial şi lateral

REZULTATE

1. Evaluarea preoperatorie. Pe cazuistica studiată, cel mai frecvent se remarcă hipoestezia plantară (50%), urmată de anestezia plantară (30%) (tab. I). Pe întreg lotul de studiu (100%) semnul TINEL a fost

pozitiv în spațiul retromaleolar intern.

În funcție de caracteristicile epidemiologice se remarcă frecvența ușor mai crescută a pierderii axonale severe la sexul masculin (p=0,673), însă distribuțiile nu au fost semnificative din punct de vedere statistic. La vârste sub 60 ani se remarcă semnificativ mai frecvent pierderea axonală severă (p=0,038) (tab. II).

Scorul preoperator cel mai frecvent întâlnit la testul cu diapazonul Riedel-Seiffer a fost 3 (41,7%), urmat de scorul 4 (25%), scoruri patologice indiferent de vârsta pacientului (fig. 5).

TABELUL I

Distribuția lotului în relație cu sensibilitatea plantară

Caracteristică epidemiologică	Hipoestezie plantară	Anestezie plantară	Hiperestezie plantară	Test de semnificație
Sex				
Feminin	10%	20%	10%	χ^2=0,14;GL=2 p=0,933
Masculin	20%	30%	10%	
Grupa de vârstă				
< 60 ani	0%	30%	20%	χ^2=5,20;GL=2 p=0,074
≥ 60 ani	30%	20%	0%	

TABELUL II

Distribuția lotului în relație cu viteza de conducere nervoasă

Caracteristică epidemiologică	Viteza de conducere nervoasă		Test de semnificație
	Pierdere axonală severă	Bloc de conducere nervoasă	
Sex			
Feminin	30%	10%	χ^2=0,18;GL=1 p=0,673
Masculin	40%	20%	
Grupa de vârstă			
< 60 ani	40%	30%	χ^2=4,29;GL=1 p=0,038
≥ 60 ani	30%	-	

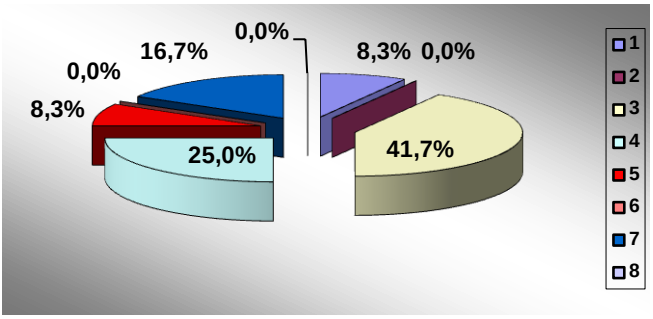

Fig. 5. Distribuția numărului de picioare în funcție de percepția vibratorie preoperatorie la testarea cu diapazonul Riedel-Seiffer

Testarea preoperatorie cu monofilamentul Semmes-Weinstein 10 g a fost pozitivă la 83,3% dintre picioare preoperator şi numai 25% postoperator, distribuție semnificativă din punct de vedere statistic (χ^2=6,04; GL=1; p=0,014).

2. Evaluarea postoperatorie. Pe cazuistica studiată, sensibilitatea plantară s-a îmbunătățit clinic, cu dispariția semnului TINEL la 9 pacienți (90%). În primele 3 luni semnul TINEL a devenit absent la peste 60% dintre pacienți, după care, la 6 luni a devenit absent la toți pacienții. Un pacient cu anestezie plantară nu a prezentat îmbunătățiri ale sensibilității plantare, dar clinic semnul TINEL a fost absent. Un singur pacient a prezentat la o lună postoperator dehiscența plăgii operatorii, refuzând reintervenția chirurgicală. La restul pacienților cu decompresiunea canalului tarsian, sensibilitatea plantară s-a îmbunătățit în proporție de 40% în primele 3 luni. După 6 luni, leziunile trofice plantare s-au vindecat complet fără alte complicații sau alte intervenții chirurgicale.

Scorul postoperator la testul cu diapazonul Riedel-Seiffer a revenit în limite normale la toți pacienții: scor 7 – 58,3% şi scor 8 – 41,7% din numărul total de picioare testate. Valorile postoperatorii ale scorului la testul diapazonului Riedel-Seiffer s-au încadrat în intervalul 7-8 indiferent de valorile inițiale, de aceea se remarcă o corelație moderat indirectă între aceste valori (r= -0,25) (fig. 6).

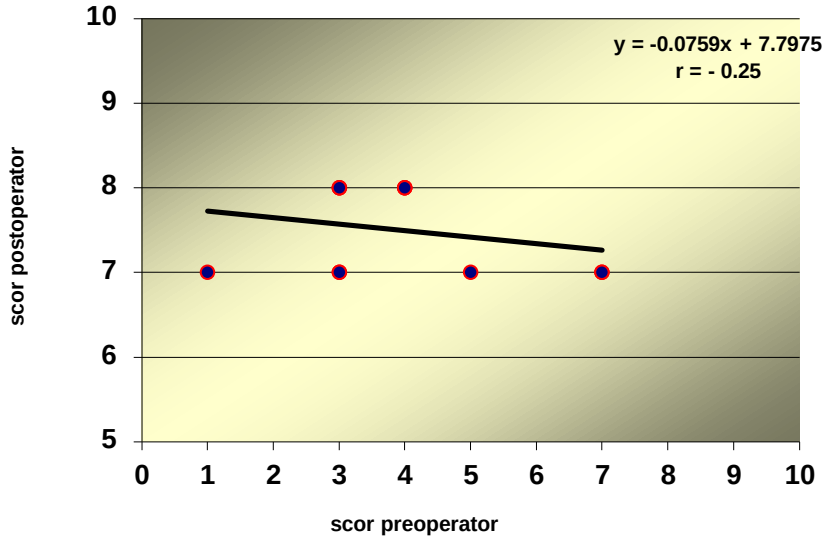

Fig. 6. Corelația dintre valorile individuale ale scorurilor pre şi post operatorii la scorul diapazonului Riedel-Seiffer

DISCUȚII

Neuropatia diabetică este complicația primară şi una din cele mai frecvente cauze de morbiditate legată de diabet. Este unul din factorii cei mai importanți în apariția ulcerației plantare la pacienții diabetici. Prevenirea acestei complicații este dificilă, în special din cauză că nu există o metodă fiabilă pentru a testa sensibilitatea plantei.

La pacienții diabetici nervii periferici se edematiază, tinzând să ducă la creşterea conținutului de apă prin creşterea conversi-

ei aldozreductazei din glucoză la sorbitol. Nervul tibial posterior este supus riscului cronic de dezvoltare a compresiunii ca urmare a edemului. Diametrul nervului tibial la pacienții diabetici cu polineuropatie este semnificativ mai mare decât la pacienții diabetici ce nu prezentau polineuropatie (24.0 vs. 12 mm^2) (1). Pierderea progresivă şi neuniformă a sensibilității pentru stimulii externi explică de ce se pot constata ulcerații la pacienții cu diabet la care o examinare neurologică grosieră a sensibilității superficiale poate duce la impresia greşită că aceasta este încă păstrată.

În acest studiu prospectiv am pus în evidență semnele clinice cele mai importante în sindromul de canal tarsian la pacienții diabetici, aspectele leziunilor trofice şi ulcerative plantare pe care polineuropatia diabetică periferică le induce alături de sindromul de canal tarsian, precum şi evaluarea pacienților din punct de vedere al testării cantitative şi semnicantitative senzoriale după decompresiunea chirurgicală a canalului tarsian. Totodată am evaluat şi pus în evidență redobândirea sensibilității plantare, dispariția durerii, şi vindecarea leziunilor plantare.

Decompresiunea chirurgicală a nervului tibial posterior a dus la redobândirea sensibilității plantare la 90 % dintre pacienți pe lotul studiat.

Vindecarea leziunilor plantare s-a produs la toți pacienții la diferite intervale de timp, cea mai lungă perioadă fiind de 1 an şi 6 luni, dar la acest pacient sensibilitatea plantară nu a revenit în limite normale după intervenția chirurgicală. In lotul de studiu, 1 singur pacient a prezentat dehiscența şi infectarea plăgii postoperatorii, dar a refuzat tratamentul.

Cuantificarea sensibilității plantare prin testarea cantitativă cu monofilamentul Semmes – Weinstein şi a percepției vibratorii cu diapazonul Riedel- Seiffer, a dus la concluzia că aceste teste pot fi folosite cu succes în evaluarea pacienților cu neuropatie diabetică pre- şi postoperator în chirurgia de decompresiune a canalului tarsian.

CONCLUZII

Cercetările au identificat că 40% dintre subiecții lotului de studiu au avut în antecedente amputații la diferite niveluri ale piciorului, toți prezentând leziuni trofice (ulcere plantare) la nivelul piciorului.

Dintre semnele clinice, cel mai frecvent s-a remarcat hipoestezia plantară (50%) iar la percuția în spațiul retromaleolar intern semnul TINEL a fost pozitiv la tot lotul de studiu.

Viteza de conducere nervoasă evidențiază cel mai frecvent pierderea axonală severă la nivelul nervului tibial posterior la nivelul gleznei (retromaleolar intern) (70%).

Sensibilitatea plantară s-a îmbunătățit clinic, cu dispariția semnului TINEL la 9 pacienți.

După 6 luni, leziunile trofice plantare s-au vindecat complet fără alte complicații sau alte intervenții chirurgicale.

Scorul postoperator la testul cu diapazonul Riedel-Seiffer a revenit în limite normale în proporție de 100%: scor 7 – 58,3% şi scor 8 – 41,7% din numărul total picioare testate.

Testarea preoperatorie cu monofilamentul Semmes-Weinstein 10 g a fost pozitivă la 83,3% dintre picioare preoperator şi numai 25% postoperator, distribuție semnificativă din punct de vedere statistic (χ^2=6,04; GL=1; p=0,014).

Decompresiunea canalului tarsian la pacienții diabetici cu polineuropatie periferică a determinat redobândirea sensibilității plantare, vindecarea leziunilor ulcerative plantare, prevenția altor ulcerații plantare și îmbunătățirea calității vieții și ar trebui luată în studiu la pacienții cu neuropatie periferică diabetică la care tratamentul conservator și/sau medical nu a dat rezultate satisfăcătoare.

SINUS TARSI APPROACH FOR TREATMENT OF DISPLACED INTRA-ARTICULAR CALCANEAL FRACTURES (Abstract): The optimal treatment for displaced calcaneal fractures involving the posterior facet is surgical. Several minimally invasive techniques have been developed in recent years. **Aim**: We evaluated the results of calcaneal posterior facet reduction by a limited sinus tarsi approach combined with percutaneous reduction and screw fixation. **Material and methods**: Twenty-three consecutive patients (mean age 41 years) with 27 intra-articular calcaneal fractures were treated. After reduction and fixation of the posterior calcaneal facet, the final fixation of the calcaneal fractures was performed percutaneously with two or three 6.5 mm, fully threaded cancellous screws. Patient follow-up was on average 1.4 years. **Results**: Superficial wound edge necrosis was observed in one case (0.27%) which has healed within one week with local wound care. The Bohler angle has improved from an average of -0.89^{o} preoperatively to 26.41^{o} postoperatively. Median AOFAS score was 89 points and median MES score was 87 points at the final follow-up. **Conclusions**: Minimally invasive open reduction and percutaneous screw fixation of selected displaced intra-articular calcaneal fractures can achieve good to excellent functional and radiological outcomes. Sinus tarsi approach appears to be an effective and reliable method for the treatment of these fractures being associated with fewer wound complications and a shorter waiting time before surgery. **Keywords**: DISPLACED INTRA-ARTICULAR CALCANEAL FRACTURES, SINUS TARSI APPROACH, CALCANEAL POSTERIOR FACET, MINIMALLY INVASIVE.

Calcaneal fractures account for 1-2% of all fractures and are the most common fractures of the tarsal bones, representing 65% of all tarsal fractures (1). Seventy percent of these fractures are intra-articular (2).

Nonsurgical treatment of displaced intra-articular calcaneal fractures is associated in general with poor results due to secondary subtalar arthrosis and modification of hindfoot morphology. For these reasons more and more surgeons advocate in favor of surgical over conservative treatment of displaced intra-articular calcaneal fractures (3-5). The optimal treatment for displaced calcaneus fractures involving the posterior facet is surgical and, for an extended period, the gold standard in the treatment of these fractures was represented by open reduction and internal fixation (ORIF) via an extended L-shaped lateral approach. However, this approach was frequently associated with major wound healing com-

plications, from 5.8% to 43%, such as skin edge necrosis, hematoma, and deep wound infection (6).

To minimize these risks, several minimally invasive techniques have been developed in recent years: closed reduction and percutaneous screw fixation (7, 8), open reduction of the posterior facet via sinus tarsi lateral approach (9, 10), limited posterior approach and arthroscopic-assisted fixation (11, 12).

In this prospective study we evaluated the results of calcaneal posterior facet reduction by a limited sinus tarsi lateral approach combined with percutaneous reduction and screw fixation of displaced intra-articular calcaneal fractures.

MATERIAL AND METHODS

Study design. Twenty-three consecutive patients, 18 (78.3%) males and 5 (21.7%) females, with 27 intra-articular calcaneal fractures were treated in the interval 2015-2016. The age of patients ranged from 24 to 78 years (mean age 41 years). The mechanism of injury was fall from height in most cases - 17 (73.9%) fractures, car accidents in 5 (21.7%) patients and direct trauma (a weight falling directly on the hindfoot) in one (4.4%) patient. Right foot was affected in 14 (60.8%) patients, left foot in 5 (21.7%) patients and four (17.4%) patients had bilateral calcaneal fractures. Two of the fractures were open: one type I and the other type IIIA according to Gustilo-Anderson classification.

Plain X-ray films were obtained for all the patients including lateral view, axial heel view (Harris view) and Broden's oblique views. Bohler's angle was measured in all patients pre- and postoperatively.

Computer Tomography (CT) scan was performed in all patients to assed the fracture patterns and for classification. Fractures were classified according to Sanders classification: 19 (70.3%) fractures Sanders type II and 8 (29.7%) fractures Sanders type III.

After the reduction and fixation of the posterior calcaneal facet, the final fixation of the calcaneal fractures was performed percutaneously with two or three 6.5 mm, fully threaded cancellous screws. The average time till surgery was 4 days (range 1-8 days) depending in general on the availability of surgical theater, and in older, active patients on comorbidity assessment (the oldest patient was 78 years old).

Seven (30.4%) patients were chronic smokers (on average more than 1.5 packs per day), 3 (13%) patients had diabetes and 1 (4.3%) patient had associated vascular disease.

Postoperative CT scan was performed in 17 (73.9%) patients to evaluate the reduction of calcaneal posterior facet.

All patients were assessed clinically and radiologically. Patients follow-up was on average 1.4 years (9 months to 1.8 years), two (8.7%) patients were excluded because were lost to after one-year follow-up. For clinical assessment we used The American Orthopedic Foot and Ankle Score (AOFAS) and Maryland Foot Score (MES).

Surgical technique. For exposure the patient is positioned in full lateral decubitus on the radiolucent operating table (fig. 1A). High tourniquet was used in all patients. The involved extremity is positioned on a cylindrical pillow and the other extremity is bent from the knee not to interfere during fluoroscopy.

Sinus tarsi approach consists in a small incision of about 3-4 cm under the tip of the lateral malleolus in the direction of the base of the fifth metatarsal bone (fig. 1B). This small incision is situated in the plane be-

tween the superficial peroneal nerve and the sural nerve and protects the lateral calcaneal artery which is responsible for most of the blood supply to the lateral calcaneal area. By sharp dissection care must be taken not to damage the peroneal tendons which are retracted laterally (fig. 1C). The incision is deepened by mobilizing the sinus tarsi fat pad dorsally. Sometimes the intermediate root of the inferior extensor retinaculum can be released to have better access to the fracture line. By now excellent visualization of the posterior facet is obtained (fig. 1D). In some cases, for better visualization of the medial articular fragment the interosseous talocalcaneal ligament could be transected, but this is not recommended because it creates subtalar instability.

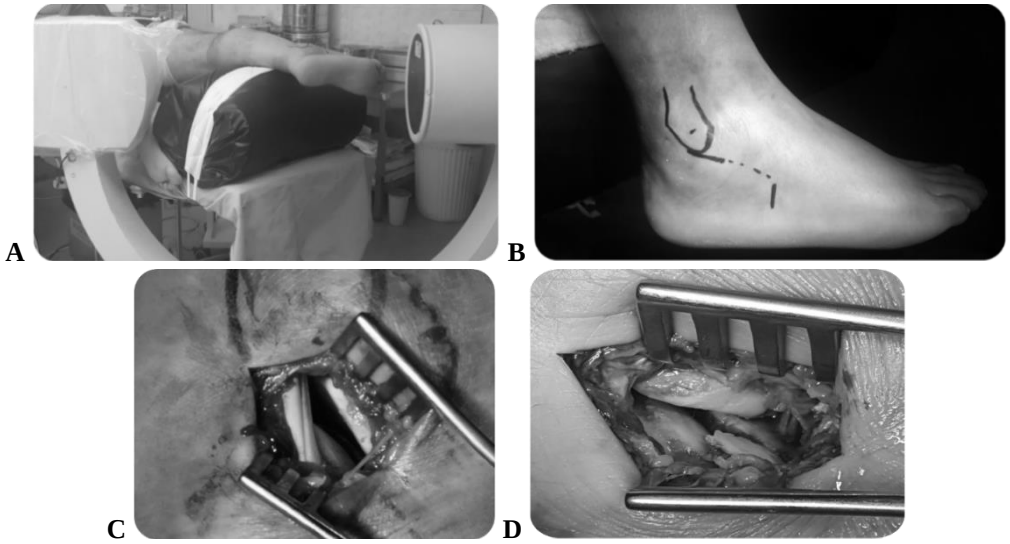

Fig. 1. A – position of the patient on the table, B – sinus tarsi approach, C – position of the peroneal tendons in the surgical field, D – visualization of the fractured calcaneal posterior facet.

A Shantz screw or a Steinman pin is used for traction and reduction of the tuberosity. After the fracture is mobilized and the interposed soft tissue is debrided, the posterior facet is reduced and fixed temporally with two, Ø 2mm, Kirschner (K) wires. The fractured fragments are reduced to the constant sustentacular fragment. Reduction of posterior facet fragments can be performed in an outside-in or inside-out-inside manner in case of a dislocated intermediate fragment.

Accurate articular surface reduction is assisted either by direct visualization or dry arthroscopy and fluoroscopically with lateral, axial heel and Broden's views. After confirming the anatomic reduction of the posterior facet, the two K-wires are replaced successively with two Ø 3.5 mm cancellous screws. The last step is the fixation of the calcaneal fracture.

Once the fixation is complete and final fluoroscopic or X-ray images are obtained, the wound is thoroughly irrigated, and the soft tissues are sutured in layers. A small closed suction drain is placed into the wound which is removed after 24-48 hours postoperatively.

All patients begun active and passive

range of motion exercises the second day after surgery.

RESULTS

No intraoperative complications occurred. The patient with open type IIIA calcaneal fracture needed plastic surgery reconstruction for skin closure. All the fractures had healed radiologically within three months (fig. 2).

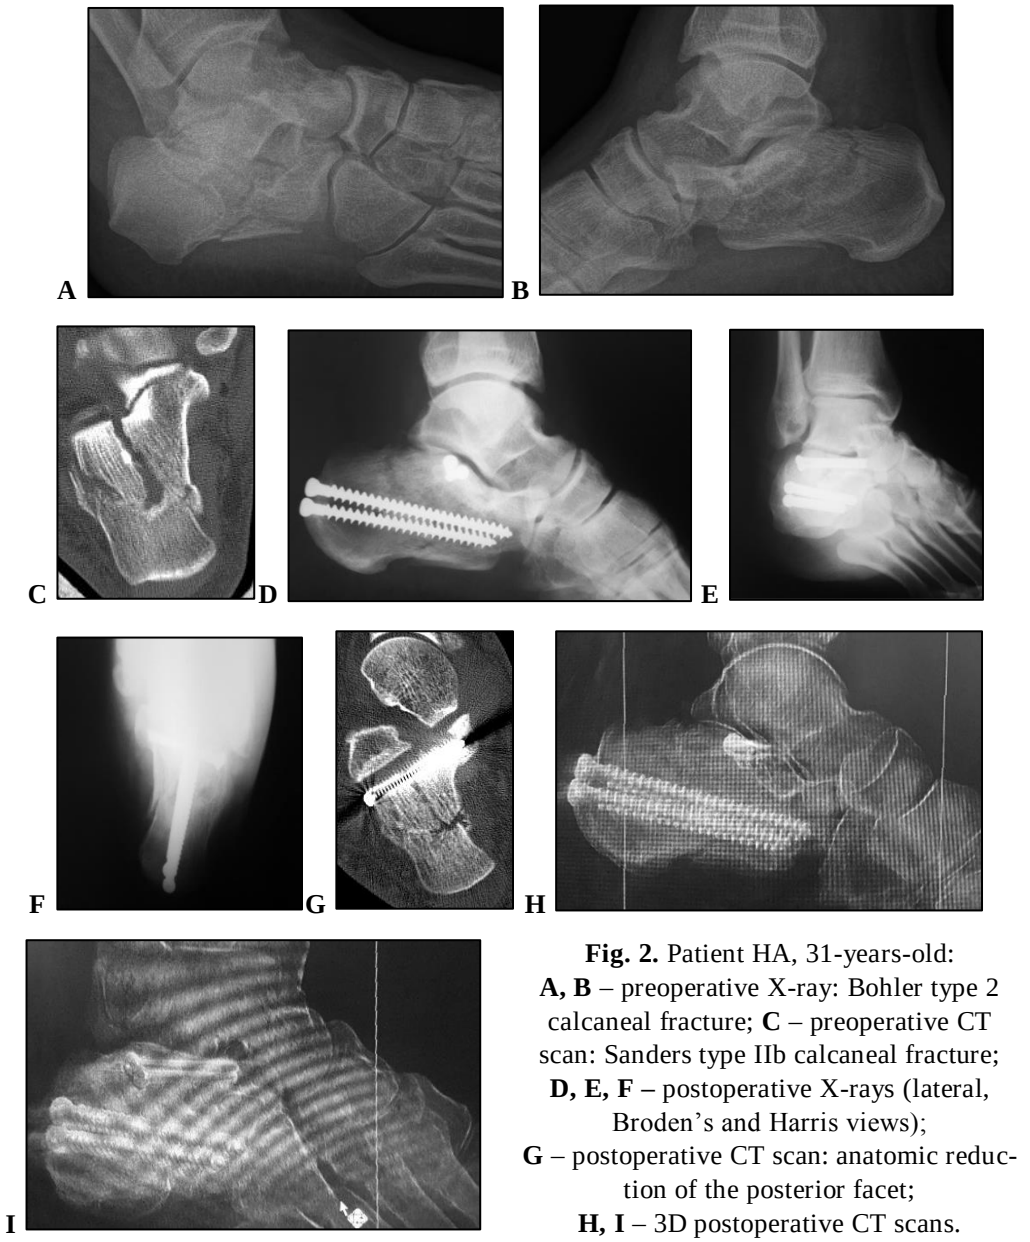

Fig. 2. Patient HA, 31-years-old:
A, B – preoperative X-ray: Bohler type 2 calcaneal fracture; **C** – preoperative CT scan: Sanders type IIb calcaneal fracture; **D, E, F –** postoperative X-rays (lateral, Broden's and Harris views); **G** – postoperative CT scan: anatomic reduction of the posterior facet; **H, I** – 3D postoperative CT scans.

Active and passive range of motions exercises were initiated from postoperative day 2. Non-weight bearing for thirty days was recommended followed by partial weight bearing (15-20 kg) for two weeks.

Superficial wound edge necrosis was observed in two cases (0.54%) which had healed within one week with local wound care. No superficial or deep infections developed in our series. In one patient we noticed, at three months follow-up, a lost in calcaneal varus reduction, without major clinical implication, probably due to intense anterior process comminution.

The Bohler angle has improved from an average of - 0.89^o preoperatively (range from -39.1^o to 11.39^o) to 26.41^o postoperatively (range from 15.23^o to 38.11^o). Postoperative CT scan showed a posterior facet step-off less than 1 mm in 12 patients, 1-2 mm in 4 patients and more than 2 mm in 1 patient.

Median AOFAS score was 89 points (range from 74 to 96) and median MES score was 87 points (range from 76 to 94) at the final follow-up.

DISCUSSION

Closed reduction and percutaneous K-wire or screw fixation have frequently been reported and can effectively reduce the risk of surgical wound complications because of the small incision (8). Open reduction of the posterior facet using a less invasive sinus tarsi approach and percutaneous screw fixation seems to be a better option (13).

In his study, Tornetta (14) was the first to report satisfactory results of percutaneous treatment of calcaneal fractures. He found a mean Maryland Foot Score of 87 in 22 patients with Sanders type IIc fractures at a mean follow-up of 2.9 years. In 2004, Rammelt *et al*. (15) found that percutaneous fixation of displaced calcaneal fractures had good to excellent results in patients with less severe fracture patterns, with a mean AOFAS ankle-hindfoot score of 94.1. In their study, Beltran and Collinge (16) including high-grade open calcaneal fractures treated with percutaneous screw fixation found good results in 17 patients, with an average AOFAS ankle-hindfoot score of 77, 1 patient developed a deep infection (6%) and 1 patient wound dehiscence (6%).

Van Hoeve *et al.* (17), in a 2016 review of the published data regarding minimally invasive treatment of intra-articular calcaneal fractures found that open and percutaneous reduction and screw osteosynthesis techniques have been used with increased frequency as an alternative to ORIF. Also, their review indicates that techniques using percutaneous reduction and screw osteosynthesis and minimally invasive open approaches result in significantly better outcomes in terms of the AOFAS ankle-hindfoot score and increased Bohler angle after treatment compared with external fixation and other techniques such as Kirschner wire fixation. No significant difference in the incidence of infection was found between these techniques. Only a few studies reported the congruency of the posterior facet of the subtalar joint as an outcome parameter.

Comparable results were found in our study, and it seems that excellent results are in close correlation with the restoration of Bohler angle and posterior facet step-out.

Open, less invasive, sinus tarsi approach with the application of the common calcaneal plate is limited to specially designed plates, which have not undergone biomechanical testing. Another option for osteosynthesis through sinus tarsi approach

are nails (18-20) which seem to offer better stability than the plates (21).

Another crucial element is that the lateral extensile incision requires delay in surgical treatment until swelling has improved, usually an average of two weeks. The current trend and interest is in small incision approaches which allow earlier operative fixation (22). The average time till surgery was 4 days in our series and this is due to prolonged preoperative period in some older patients (two patients were older than 70 years) who needed complex health assessment due to their frailty (23). In our country, older patients are sometimes self-neglected, and these conditions require a complex preoperative management in such cases (24).

CONCLUSIONS

We believe that minimally invasive open reduction and percutaneous screw fixation of selected displaced intra-articular calcaneal fractures can achieve good to excellent functional and radiological outcomes. Sinus tarsi approach appears to be an effective and reliable method for the treatment of these fractures being associated with fewer wound complications and a shorter waiting time for surgery.

NEWS

GHRELIN PLAYS AN IMPORTANT ROLE IN METABOLIC DISEASES

Changes in ghrelin levels can directly affect immune responses and tissue homeostasis. Leukocytes, such as adipose tissue macrophages, express GHS-R and detect changes in energy status. Thus, ghrelin actions on ATMs may play a role in the maintenance of the tissue homeostasis, suggesting a link between the immune system and systemic metabolism in response to different physiological and pathological conditions such as obesity and insulin resistance. Immunoregulatory role of acyl-ghrelin and its beneficial effects to treat chronic inflammatory syndromes, especially acyl-ghrelin immunoprotected properties during endotoxic shock has been demonstrated. Ghrelin is not only a gastric peptide with CNS actions, but it is also an important hormone/cytokine with important pleiotropic functions. The wide distribution of GHS-R1a in different cell types, including immune cells, indicates that ghrelin acts as a potent immunomodulator with powerful anti-inflammatory roles. Ghrelin mainly acts on the innate and adaptive immune systems to suppress inflammation and induce an anti-inflammatory profile. (Jéssica Aparecida da Silva Pereira, Felipe Corrêa da Silva, Pedro Manoel Mendes de Moraes-Vieira, The Impact of Ghrelin in Metabolic Diseases: An Immune Perspective, *J Diabetes Res* Volume 2017:1-15)

SYPHILIS IN PREGNANCY (Abstract): Inadequately treated, maternal syphilis often results in serious sequels for the fetus/newborn. Poor prenatal care is a major risk factor for the development of congenital syphilis. **Aim:** To determine the results of syphilis screening and follow-up programs on the incidence of syphilis in pregnant women and their offspring. **Material and methods:** Data on the incidence of syphilis, new syphilis cases, pregnant women diagnosed with syphilis and newborns confirmed with congenital syphilis in the Iasi district in the interval 2000-2009 have been collected. **Results:** In the interval 2000-2010 the incidence of syphilis in the Iasi district has decreased from 47.5/100,000 inhabitant in 2001 to 10.5% in 2009, and the new syphilis cases from 627 in 2001 to 87 in 2009. The highest number of pregnant women infected with syphilis was recorded in 2006 (74), and the lowest in 2010 (26). Most newborns confirmed with congenital syphilis were also recorded in 2006 (6), in the interval 2008-2010 no such case being recorded. **Conclusions:** All pregnant women have to be subjected to a serological screening test for syphilis at least twice during pregnancy: early during the first trimester and after week 28. Moreover, the women at risk for syphilis have to be examined serologically at delivery. All women who miscarry after 20 weeks of gestation have to be tested for syphilis. All newborns whose mothers' serological status for syphilis was not determined during pregnancy have to be tested before discharge. **Key words**: PREGNANCY, PRENATAL DIAGNOSIS, CONGENITAL SYPHILIS, NEWBORNS SEROLOGICAL STATUS

Sifilisul este o infecție cronică sistemică determinată de *Treponema pallidum*, transmisă de obicei sexual şi caracterizată prin episoade de boală activă întrerupte de perioade de latentă (1). După o incubație de aproximativ 3 săptămani, apare la poarta de intrare a treponemei o leziune primară, care este adesea asociată cu limfadenopatie regională; stadiul secundar este asociat cu leziuni mucocutanate generalizate, urmat de o perioadă latentă de infecție subclinică, cu o durată de mai mulți ani. În aproape o treime din cazurile netratate, boala evoluează spre stadiul terțiar caracterizat prin leziuni mucocutanate distructive, progresive, musculoscheletice sau parenchimatoase, aortită sau boală simptomatică a sistemului nervos central (2, 3, 4).

Agentul cauzal, un microorganism spiralat, subțire, mobil, de 5-15µm lungime şi 0,1-0,2µm grosime, cu 6-14 spire, poate fi pus în evidență prin microscopie în camp întunecat în stare vie în serozitatea din leziuni, prin metode de colorare şi impregnare, metode de imunofluorescență, microscopie în contrast de fază, microscopie electronică (5, 6). Aceasta din urmă relevă că microorganismul este constituit dintr-un

cilindru protoplasmic, un nucleu, un periplast, filamente axiale şi o membrană externă. Se reproduce prin diviziune transversală la 30 de ore.

Treponema pallidum este fragilă, supravieţuirea în afara organismului fiind redusă. Este distrusă prin căldură, uscare, spălare cu apă şi săpun, antiseptice uzuale. Congelată în ţesuturi la -78ºC, îşi păstrează viabilitatea şi virulenţa până la 9 ani. Nu poate fi cultivată pe medii artificiale, dar poate fi menţinută pe culturi de ţesuturi şi poate fi inoculată la animale (maimuţă, iepure (1, 2, 7, 8, 9).

Interesul pentru sifilis se menţine din următoarele motive:

- capacitatea acestei boli de a produce rapid epidemii, prin contagiozitate crescută, chiar şi în condiţiile unei morbidităţi scăzute;

- imposibilitatea eradicării ei şi menţinerea unei morbidităţi staţionare, dar cu posibilitatea apariţiei de noi epidemii la cea mai mică scădere a vigilenţei;

- repercursiunile infecţiei luetice asupra individului, la care produce, după mai mulţi ani de evoluţie, leziuni ireversibile ale sistemului nervos (paralizie generală progresivă) şi ale aparatului cardiovascular;

- posibilitatea transmiterii infecţiei şi pe cale nevenerianã (5), în special la descendenţi, cu consecinţe catastrofale asupra produsului de concepţie;

- uşurinţei cu care boala poate fi transmisă dintr-o ţară în alta, în epoca modernă (4).

MATERIAL ŞI METODE

Studiul a fost efectuat pe un lot de 426 gravide diagnosticate cu sifilis şi un lot de 31 nou-născuţi, confirmaţi cu sifilis congenital, din judeţul Iaşi, în perioada 2002-2010.

Culegerea datelor a fost realizată retroprospectiv, utilizându-se registrele de statistică ale Direcţiei de Sănătate Publică Iaşi.

Prelucrarea datelor s-a efectuat prin metode epidemiologice clasice şi computerizate, cu ajutorul programului MS EXCEL 2007.

REZULTATE

Distribuţia cazurilor pe ani calendaristici a arătat o incidenţă maximă în 2006 (74 cazuri – 17,4% din totalul lotului studiat, de 426) şi un minim în anul 2010 (26 cazuri – 6,1%). Se observă o tendinţă descrescătoare a incidenţei.

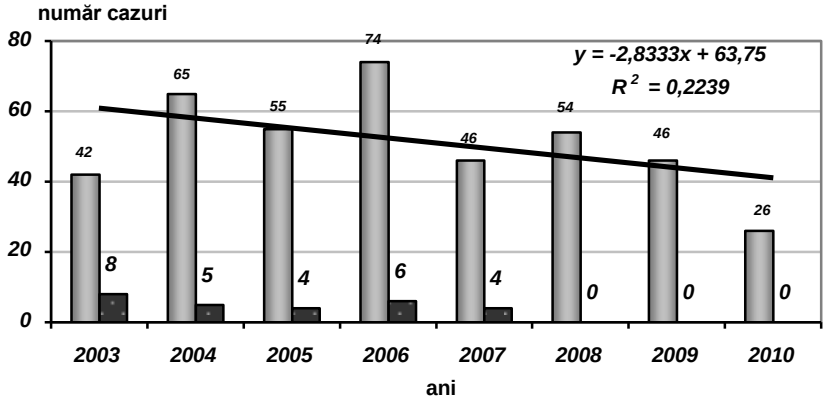

Fig. 1. Distribuţia anuală a cazurilor de sifilis la gravide şi şi nou-născuţi, în judeţul Iaşi, în perioada 2003-2010

Referitor la cazurile de nou-născuţi confirmate cu sifilis congenital, în perioada 2002-2010, acestea au prezentat o incidenţă maximă în anul 2003 (8 cazuri – 25,8% din totalul lotului de 31) şi zero cazuri raportate în anii 2008, 2009 şi în 2010 (tab. I, fig. 1).

Repartiţia pe medii de origine a femeilor luate în studiu a relevat o predominanţă a cazurilor din rural, cu valori de 19 (61,3%), comparativ cu cele provenite din urban – 12 femei (38,7%) (tab. I, fig. 2).

În perioada sarcinii, au fost luate în evidenţă au fost în număr de 12 gravide şi 19 nu au accesat niciodată un cabinet medical.

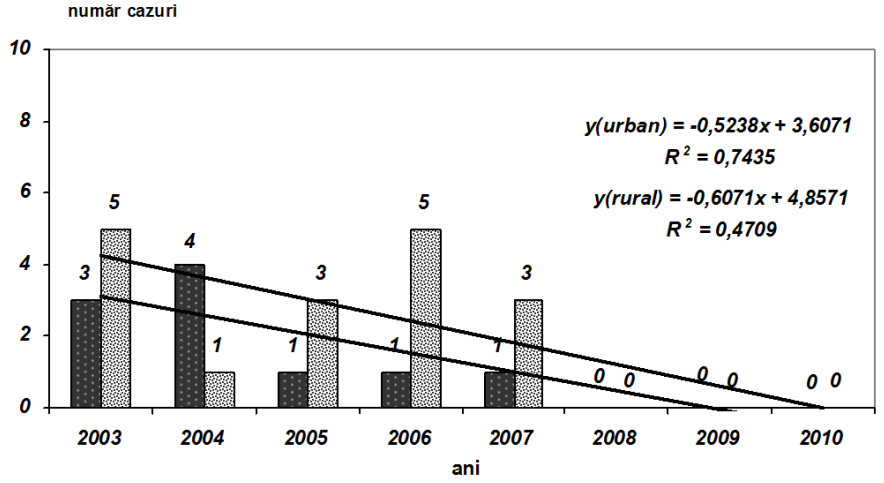

Fig. 2. Repartiţia anuală şi pe medii a cazurilor de sifilis la mamele care au născut copii cu sifilis congenital, în judeţul Iaşi, în perioada 2003-2010

Testarea pentru sifilis în timpul sarcinii a fost efectuată doar de 10 (32,3%) gravide din cele 31 care au născut copii cu sifilis congenital, iar restul de 21 (67,7%) nu s-au prezentat la aceasta, deşi testul este gratuit.

Rezultatele cercetărilor noastre sunt în acord cu cele ale altor studii publicate în ţară şi străinătate (4, 5, 7).

DISCUŢII

Intensitatea infecţiei luetice materne determină şi gravitatea manifestărilor fetale. Astfel, o septicemie treponemică a mamei are drept consecinţă o masivă infecţie spirochetică a fătului, conducând la avorturi spontane şi naşteri premature, moartea intrauterină a fătului, naşteri de feţi care prezintă imediat sau în cursul primilor 2 ani manifestări de sifilic congenital precoce.

Sifilisul congenital (prenatal) este împărţit în sifilis congenital precoce şi tardiv. Sifilisul congenital precoce reprezintă un coeficient de 1,5% din totalul cazurilor de sifilis congenital, sifilisul congenital tardiv cu manifestări clinice 72% din cazuri, iar sifilisul congenital pur seriologic 26,5% din cazuri.

Se consideră că agentul etiologic se transmite la făt transplacentar după 16-18 săptămâni de sarcină, datorita aparitiei discontinuităţii stratului celulelor Langhans (7). Riscul transmiterii la făt este direct proporţional cu durata infecţiei materne netratate.

Treponema pallidum nu traversează placenta în cursul primelor luni datorită grosimii trofoplastului vilozitar (8). Cu cât contaminarea maternă survine mai târziu în evoluţia sarcinii, cu atât este mai mare riscul ca nou-născutul să fie infectat. Studii recente au identificat *Treponema pallidum* în avorturile din primul trimestru la femeile cu infecţii sifilitice recente.

Evoluţia sifilisului latent nu este influenţată de prezenţa sarcinii. Dacă afecţiunea este dobândită în timpul sarcinii, perioada de incubaţie este mai scurtă (10-12 zile), şancrul sifilitic este mai mare, însoţit de edem, datorită vascularizaţiei mai abundente a organelor genitale. În absenţa tratamentului, evoluţia leziunilor se poate prelungi până la termen, împiedicând dilataţia colului atunci când sunt localizate la acest nivel (goma sifitică localizată pe colul uterin poate împiedica dilataţia şi naşterea pe cale naturală). În perioada terţiară, diagnosticul este serologic. Leziunile din perioada secundară sunt mai întinse şi uneori se complică cu ulceraţii vulvare.

Sifilisul florid al gravidelor este motiv legal de întrerupere a sarcinii în ţările în care avortul nu este legalizat.

Astăzi este admis că o mamă cu lues recent, netratat, transmite fătului boala în 70-100% din cazuri. Femeile cu sifilis latent tardiv pot naşte copii sănătoşi (dar care fac un sifilis congenital tardiv) şi rareori copii cu sifilis florid. În ultimile decenii, cazurile de sifilis congenital sunt rare, fiind totuşi prezente în majoritatea ţărilor. Încă nu se stie precis ce influenţă are boala mamei în primele 3 luni de dezvoltare a fătului. Specialistii sunt de acord că un copil născut dintr-o mamă sifilitică, care a fost corect tratată, nu poate fi prezenta sifilis congenital.

Potrivit unui studiu realizat de Institutul Naţional de Cercetare şi Dezvoltare în Sănătate (INCDS), începând cu anul 1989, incidenţa prin sifilis a început să crească de la an la an, ajungând în 2002 la o valoare de 58,3‰, faţă de 23,3 în 1990, iar în anul 2009 s-a inregistrat o incidenţă de 15,1‰. În România, incidenţa sifilisului ramane pe primul loc în ţările din UE (10).

CONCLUZII

Sifilisul rămâne o problemă de sănătate importantă pentru femei. Tratată incorect, boala maternală lasă deseori sechele serioa-

se nou-născutului. Îngrijirea prenatală precară reprezintă un factor de risc major în dezvoltarea sifilisului congenital. În mod evident, accesul mai uşor la îngrijirea prenatală este o componentă importantă a strategiei de prevenire a bolii.

Toate femeile gravide trebuie să efectueze un test de *screening* serologic pentru sifilis de cel puțin două ori pe parcursul sarcinii: în primul trimestru, cât mai precoce şi după a 28-a săptămână de sarcină. În plus, grupurile la risc pentru sifilis vor fi examinate serologic şi cu ocazia naşterii. Toate femeile care au pierdut o sarcină după a 20-a săptămână de gestație vor fi testate pentru sifilis.

Toți nou-născuții din mame al căror status serologic pentru sifilis nu a fost determinat pe parcursul sarcinii vor fi obligatoriu testați înainte de externarea din spital.

IMPROVEMENT OF GENETIC DIAGNOSTIC STRATEGY IN VELO-CARDIO-FACIAL SYNDROME (Abstract): Velo-Cardio-Facial Syndrome (VCFS) is characterized by congenital heart defects (CHD), palatal abnormalities, facial dysmorphism, neonatal hypocalcemia, immune deficit, speech and learning disabilities. SVCF is caused by microdeletion 22q11.2. Microdeletion is detected by fluorescence in situ hybridization (FISH). The highly variable phenotype makes diagnosis and selection for FISH more difficult. **Aim:** To retrospectively analyze and compare the phenotype of children with a clinical diagnosis of VCFS with/without 22q11 deletion; to verify the validity of literature guidelines and to describe combinations of clinical features that should lead to molecular analysis. **Material and methods:** The present study was performed in 21 patients with a clinical diagnosis of VCFS. Methaphase chromosome spreads were prepared from phytohaemagglutinin stimulated lymphocyte culture by standard methods before FISH. The patients were divided into two groups according to FISH test: positive and negative. **Results:** The features commonly noticed in FISH positive patients were: palatal abnormalities/ hypernasal speech, learning disabilities, facial dysmorphism, tapered fingers (6/6), CHD (5/6) and recurrent infections (2/6). In FISH negative patients the following were found: learning disabilities, CHD (12/15), facial dysmorphism (10/15), family history of CHD (7/15), short stature (6/15), hypocalcemia, tapered fingers (5/15), recurrent infections (3/15) and palatal cleft (2/15). In both groups, Tobias and McDonald-McGinn guidelines were positive. **Conclusions:** VCFS has a highly variable phenotype. Our study suggests that 22q11.2 deletion analysis by FISH should be performed in patients who have at least 2 (newborn)/ 3 (child, adult) specific criteria: CHD, hypocalcemia, palatal abnormalities, facial dysmorphism, learning disabilities, digital anomalies, and immune deficit. **Key words**: VELO-CARDIO-FACIAL SYNDROME, GENETIC DIAGNOSTIC.

Sindromul velo-cardio-facial (SVCF) reprezintă un spectru fenotipic larg şi variabil care cuprinde anomalii velo-palatine (cu diferite grade de severitate, de la despicături până la vorbire nazală), malformaţii cardiace (MCC) (în special conotruncale), dismorfie facială sugestivă (faţa lungă, posibil asimetrică în timpul plânsului, hipoplazie malară, nas bulbos/ tubular/ proeminent, cu hipoplazia aripilor nazale, urechi jos inserate/ protuberante cu anomalii ale helixului, filtru scurt şi microstomie), hipoplazia timusului

(deficite imune) şi a glandelor paratiroide (hipocalcemie), dificultăţi de învăţare şi tulburări psihice, la care se adaugă o multitudine de semne clinice. SVCF este produs prin microdeleţia 22q11.2 (1).

Numărul semnelor clinice identificate în SVCF depăşeşte 180 (2), fiind posibilă afectarea oricărui organ şi sistem, iar gravitatea spectrului variază extrem, de la forme severe cu potenţial letal în perioada neonatală (sindromul DiGeorge) până la forme uşoare cu dismorfie facială şi vorbire nazală sau hipoparatiroidism tranzitoriu. Variabilitatea clinică, raportată inclusiv intrafamilial, nu depinde de mărimea microdeleţiei (care poate varia de la 1,5 Mb la 3 Mb) (3).

Sindromul velo-cardio-facial este una dintre cele mai frecvente boli cromozomiale, prevalenţa sa variind între 1: 2.000 şi 1: 4.000 persoane (2, 4). Frecvent microdeleţia 22q11.2. apare *de novo*, dar poate fi moştenită în 6 - 28% din cazuri (5).

La nivelul regiunii implicate în deleţie au fost identificate mai mult de 50 de gene. Dintre acestea un rol major îl are gena *TBX1,* care codifică un factor de transcripţie implicat în reglarea proceselor de dezvoltare embrionară a arcurilor branhiale şi a câmpului de dezvoltare cardiac. Haploinsuficienţa acestei gene explică o mare parte din semnele ce alcătuiesc spectrul clinic al microdeleţiei 22q11.2: anomaliile de dezvoltare cardiace, timice, otice. Printre genele candidat pentru retardul mental, dificultăţile de învăţare şi susceptibilitatea la dezvoltarea de tulburări psihiatrice pot fi menţionate *PRODH, COMT* şi *RTN4R* (5, 6).

Diagnosticul de certitudine al sindromului velo-cardio-facial este pus prin tehnici de citogenetică moleculară: hibridizarea fluorescentă in situ (FISH), amplificarea multiplex a probei prin legare (MLPA) sau hibridizarea genomică comparată (CGH). Testele moleculare fiind costisitoare, este necesară o selecţie fenotipică a cazurilor folosind un algoritm bazat pe frecvenţa şi importanţa semnelor clinice. Diagnosticul precoce este util în stabilirea unui management adecvat şi acordarea unui sfat genetic corect (7-9).

MATERIAL ŞI METODĂ

Pacienţii

Studiul a fost realizat retrospectiv pe 21 de pacienţi, evaluaţi în Centrul de Genetică Medicală Iaşi, între anii 2003-2010, suspicionaţi clinic de SVCF, la care s-a efectuat testul FISH pentru confirmarea diagnosticului clinic.

Metode

Preparatele cromozomiale au fost obţinute prin metode standard, folosind culturi de limfocite stimulate cu fitohemaglutinină. Pentru tehnica FISH au fost utilizate sonda LSI TUPLE1 (HIRA) (Abbott Molecular, Vysis®), localizată în regiunea frecvent afectată de microdeleţie şi marcată cu fluorocromul Spectrum Orange şi sonda control LSI ARSA (Abbott Molecular, Vysis®), localizată în regiunea 22q13 şi marcată cu fluorocromul Spectrum Green. În funcţie de rezultatul acestei analize pacienţii au fost repartizaţi în 2 loturi: lotul A, FISH pozitiv - pacienţi la care diagnosticul de sindrom velo-cardio-facial a fost confirmat şi lotul B, cazuri infirmate, cu FISH negativ. Lotul A cuprinde 6 pacienţi, 2 de sex feminin şi 4 de sex masculin, cu vârste cuprinse între 1 lună şi 33 de ani. Lotul B cuprinde 15 pacienţi, 5 de sex feminin şi 10 de sex masculin, cu vârste cuprinse între 1 săptămână şi 16 ani. Semnele clinice prezente la pacienţii celor două loturi au fost comparate cu semnele clinice corespunzătoare algoritmului propus de Tobias *et al*. în 1999 şi scorului McDonald-McGinn *et*

al. din 2001 (3, 7).

REZULTATE

Analiza citogenetică a 21 de pacienţi cu diagnosticul clinic de SVCF a confirmat microdeleţia 22q11.2 în 6 cazuri (pacienţi ce formează lotul A) şi a infirmat-o în 15 cazuri (lot B).

În lotul A, cu diagnostic cert, patru semne clinice au fost prezente la toate cazurile: dismorfia facială, insuficienţa palatină/vocea nazală, dificultăţile de învăţare, şi prezenţa de degete lungi, conice. Alte două elemente de diagnostic au fost întâlnite: MCC (non-conotruncale) în 83% din cazuri, iar infecţiile repetate au fost prezente în 33% din cazuri. În lotul B (infirmat prin FISH), semnele clinice cele mai frecvente au fost MCC şi dificultăţile de învăţare, la 80% din cazuri, dismorfia facială în 66%, hipocalcemia în 33%, infecţiile repetate în 20%, iar anomaliile palatine în 13% din cazuri.

Scorul clinic al pacienţilor din lotul A a variat, pentru algoritmul Tobias, între următoarele asocieri de semne: (1 criteriu A + 4 criterii B + 1 criteriu C) şi (2 criterii B + 1 criteriu C) şi, pentru scorul Mc Donald-McGinn, între 4 - 5,5 puncte (tabelul I). În lotul B scorurile clinice au variat între (1A+1B+1C) şi (1B+2C) şi, respectiv, între 3 – 4 puncte (tab. I).

TABELUL I

Scoruri de diagnostic în cele 2 loturi

Semn clinic	Algoritm Tobias	Scor Mc Donald-McGinn	Lot A	Lot B
MCC conotruncale	Clasa A	1 punct	0/6	3/15
Un părinte cu SVCF	Clasa A	-	1/6	0/15
Dismorfie facială	Clasa B	¼ punct	6/6	10/15
MCC nonconotruncale	Clasa B	1p	5/6	9/15
Dificultăţi de învăţare/ retard psihomotor	Clasa B	1/2 punct / RM moderat	6/6	12/15
Insuficienţă velopalatină	Clasa B	1 punct	5/6	2/15
Hipocalcemie	Clasa B	1 punct	0/6	5/15
Imunodeficienţă	Clasa B	1 punct	2/6	3/15
Anomalii digitale	Clasa C	½ punct	6/6	5/15
Anomalii renale	Clasa C	½ punct	1/6	1/15
Hipotonie	Clasa C	-	0/6	1/15
Hipostatură	Clasa C	½ punct	0/6	6/15
Tulburări psihiatrice	Clasa C	½ punct	?	?
MCC familiale	Clasa C	-	2/6	7/15
Voce nazală	-	¼ punct	6/6	2/15
Indicaţie de FISH	1 criteriu A sau 2 criterii B sau 1B+minim 1C	Minim 3 puncte		

Pentru ambele loturi scorurile obţinute au fost superioare pragului la care era recomandată testarea pacienţilor în studiile respective.

DISCUŢII

Spectrul fenotipic al sindromului velo-cardio-facial este variabil, incluzând numeroase anomalii, în diverse combinaţii şi cu grade de severitate diferite. Această variabilitate este determinată de factori multipli: evoluţia fenotipului în funcţie de vârstă, variabilitatea genetică, prezenţa de gene modificatoare şi fenocopiile (10). Tabloul clinic clasic include anomalii palatine, MCC conotruncale şi dismorfie facială. În lotul A se remarcă asocierea între anomalii palatine (inclusiv voce nazală), dismorfie facială şi dificultăţile de învăţare. Anomaliile velopalatine, deşi cu un grad redus de severitate (insuficienţă velopalatină) sunt prezentate în lotul A la toate cazurile, spre deosebire de lotul B unde, deşi severitatea era crescută (despicături maxilopalatine), numărul de cazuri era mic (2/15). În acest context vocea nazală, care trădează deficitul funcţional al vălului palatin, a constituit un element valoros de diagnostic (6/6 în lotul A).

MCC au fost prezente în ambele loturi în proporţii similare (A - 83%, B - 80%) (corespunzând datelor de literatură - 80%) (4); prezenţa în lotul B a MCC conotruncale (3/15) sugerează că, deşi sunt tipul de MCC cel mai frecvent în SVCF (7-50%) (4, 9), este necesară asocierea acestora cu alte elemente sugestive de diagnostic pentru a necesita aplicarea tehnicii moleculare. Am observat că anamneza familială pozitivă pentru MCC a fost prezentă la un număr ridicat de cazuri în lotul B faţă de A, ceea ce pune la îndoială valoarea acestui criteriu, având în vedere frecvenţa mare în populaţia generală a cazurilor de MCC familiale.

Dismorfia facială s-a dovedit a fi un criteriu valoros, dar din păcate subiectiv în apreciere şi care devine evident doar odată cu înaintarea în vârstă. Dintre elementele dismorfiei faciale utile s-au dovedit: faţa lungă, posibil asimetrică în timpul plânsului, (5/6 faţă de 5/15), hipoplazia malară (5/6 faţă de 3/15), nasul bulbos/tubular/ proeminent (6/6 faţă de 6/15) şi hipoplazia aripilor nazale (5/6 faţă de 4/15). Alte elemente valoroase dar fără diferenţe semnificative între cele 2 loturi au fost urechi jos inserate/ protuberante (4/6 şi 13/15) şi anomaliile helixului (4/6 şi 10/15).

Dificultăţile de învăţare reprezintă un criteriu important pentru diagnosticul clinic de SVCF, dar din păcate corelat cu vârsta pacientului. Deşi scorul Mc Donald-McGinn cuprindea retardul mental (RM) moderat, mulţi dintre pacienţii noştri prezentau doar dificultăţi uşoare, iar în cazul studiului de faţă RM moderat a fost prezent doar în lotul B. Pe de altă parte, tulburările psihiatrice au debut tardiv, iar lotul nostru a cuprins preponderent pacienţi de vârstă pediatrică, astfel încât este necesară urmărirea ulterioară a cazurilor pentru a detecta astfel de modificări.

Deşi în literatura de specialitate, hipocalcemia este considerată un criteriu valoros pentru diagnosticul SVCF (simptom prezent la 17-60% din pacienţi) (8), aprecierea semnificaţiei acestei modificări biochimice la pacienţii noştri a fost dificilă deoarece ei au fost testaţi sporadic şi incomplet (doar dozarea calciului total, dozările calciului ionic şi parathormonului nefiind realizate), ceea ce nu ne permite concluzii pertinente. Aceleaşi rezerve există şi în privinţa imunodeficienţei care a fost apreciată doar declarativ (prin numărul de infecţii repetate).

Aspectul degetelor (lungi, conice) a fost un element valoros pentru diagnostic, fiind prezent în toate cazurile confirmate şi doar la 33% din pacienţii din lotul B. Anomaliile scheletice au fost întâlnite doar în câteva

cazuri: bloc vertebral (un caz lot A), *spina bifida* (un caz lot B) şi *pectus excavatum* (un caz lot B). Hipostatura nu s-a dovedit a fi un criteriu valabil de orientare, existând diferenţe semnificative între cele 2 loturi (0/6 faţă de 6/15).

Anomaliile renale, citate în literatură la 15 - 32% din cazuri (15), au fost întâlnite în 2 cazuri: agenezie renală unilaterală (un caz lot A) şi hidronefroză grad IV (un caz lot B). În 3 cazuri au fost prezente anomalii genitale: hipospadias (un caz lot A) şi criptorhidism (2 cazuri lot B).

Malformaţiile sistemului nervos central, hipotonia şi convulsiile nu au reprezentat criterii utile de orientare în acest studiu.

La pacienţii incluşi în studiu prezenţa semnelor clinice meţionate mai sus a fost punctată folosind o grilă elaborată de Centrul de Genetică Medicală Iaşi (tab. II). Astfel, efectuarea testului FISH este recomandată la nou-născut dacă scorul clinic este de minim 2 puncte, iar ulterior, la copil şi adolescent, de minimum 3 puncte.

TABELUL II

Grilă de evaluare a scorului clinic al pacienţilor cu SVCF în vederea testării FISH, elaborată în Centrul de Genetică Medicală Iaşi

Anomalii	Tipuri/observaţii	Punctaj
MCC	Conotruncale/ defecte septale	1 punct
Anomalii velopalatine	Despicături, insuficienţă velopalatină, inclusiv voce nazală	1 punct
Hipocalcemia	Ca ionic sau parathormon	1 punct
Retardul psihomotor/ dificultăţile de învăţare/ tulburări psihiatrice	Profil psihiatric caracteristic (deficit de atenţie, hiperactivitate, schizofrenie, tulburări bipolare)	1 punct

* necesită un evaluator experimentat

În condiţiile în care 6 - 28% din cazurile de SVCF sunt moştenite, iar variabilitatea intrafamilială poate fi importantă (adesea părinţii purtători ai microdeleţiei având un fenotip discret), screening-ul familial este un element indispensabil pentru acordarea unui sfat genetic corect.

Este evident că procesul de selecţie a pacienţilor rămâne elementul esenţial al oricărei strategii de diagnostic căci, chiar cu cel mai performant şi ieftin test de diagnostic, testarea globală a populaţiei nu

este posibilă.

CONCLUZII

Studiul retrospectiv prezentat în acest articol a permis diagnosticul a 6 pacienţi cu microdeleţie 22q11.2 într-o perioadă de 7 ani. În condiţiile în care incidenţa la naştere a SVCF este de 1/2.000 – 1/4.000 nounăscuţi, este evident că pacienţii diagnosticaţi reprezintă doar „vârful aisberg-ului".

Spectrul clinic al sindromului DiGeorge este extrem de variabil, atât intrafamilial, cât şi la nivelul populaţiei. Diagnosticul de certitudine se poate face numai prin tehnici de citogenetică moleculară, selectând cazurile cu elementele fenotipice cele mai evocatoare. Pentru a creşte eficienţa acestui proces de selecţie am elaborat un scor clinic, prezentat în tabelul II şi care considerăm că este util în practica medicală.

DIAGNOSTIC AND TREATMENT ALGORITHM FOR PHARINGOLARYNGEAL REFLUX (Abstract): Pharyngolaryngeal reflux (PLR) refers to backflow of stomach contents into the throat and larynx. Its diagnosis is difficult because of a variety of atypical symptoms, low sensitivity of traditional tests of gastrointestinal tract, and no consensus on the diagnostic algorithm. The aim of this study was to provide an algorithm for the diagnosis and treatment of PLR. There were no pathognomonic symptoms or findings, but the characteristic symptoms validate the Reflux Symptom Index and Reflux Findings Score as tools in the initial diagnosis. The first approach is empirical medical treatment for 3 month, based on endoscopic findings at laryngofiberscopy; then objective demonstration of reflux events using multichannel intraluminal impedance and pH monitoring. Proton pump inhibitors represent the mainstay of therapy for the patients with PLR, but they require a more aggressive and prolonged treatment than the patients with gastroesophageal symptoms. **Key words**: PHARYNGOLARYNGEAL REFLUX, PH MONITORING, PROTON PUMP INHIBITORS

Simptomatologia şi semnele clinice determinate de reflux au fost identificate la 4 până la 10% din toți pacienții consultați de otorinolaringologi (1). Datele din literatură arată că peste 50% din pacienții cu disfonie au afecțiuni induse de boala de reflux gastroesofagian (2). Simptomatologia şi semnele clinice obişnuite ale laringitei de reflux sunt răguşeala matinală, timpul de încălzire vocală mai mare de 20-30 minute, halitoza, hemaj, xerostomie, limba saburală, globus faringeus, disfagie, regurgitații ale conținutului gastric, tuse cronică, predominant nocturnă, tuse recurentă, ocazional pneumonie, laringospasm, decompensări ale astmului bronşic, infecții acute de căi respiratorii superioare la copii.

Uneori este dificil de diagnosticat faringolaringita de reflux, iar diagnosticarea incorectă conduce la costuri inutile pentru societate. Simptomatologia tipică de FLR este nespecifică şi poate fi cauzată de infecții (bacteriene sau virale), alergie, fumat, abuz de alcool (3), de aceea este important să existe un algoritm de diagnostic şi tratament pentru această afecțiune extra-

esofagiană indusă de reflux.

PATOFIZIOLOGIE

Incidența esofagitei de reflux este relativ scăzută, deoarece mucoasa esofagiană din porțiunea distală a esofagului are mecanisme proprii de protecție antiacidă. Aceste mecanisme includ peristaltismul (care, prin mișcările produse, indepărtează rapid acidul de pe suprafața mucoasei esofagiene), structura mucoasei (permite tolerarea unui contact intermitent cu acidul gastric), capacitatea salivei înghițită de a neutraliza acidul la nivel esofagian, producția de bicarbonat din esofag (4). Laringele şi faringele însă, nu au aceste mecanisme de protecție, astfel că expunerea la acid şi pepsina pot determina modificări substanțiale la acest nivel, în timp ce esofagul nu este deloc afectat. Datele preliminare raportate de Axford sugerează că mucoasa laringiană are un mecanism celular de aparare diferit de cel al mucoasei esofagiene şi că există diferențe specifice în expresia genei MUC şi a anhidrazei carbonice la nivelul laringelui şi faringelui (3,5).

Spre deosebire de BRGE, FLR nu se asociază frecvent cu pirozis şi regurgitații (doar 20% dintre pacienți, față de 83% în BRGE, prezintă această simptomatologie) (1). Nu există simptome sau semne clinice patognomonice pentru FLR, dar la nivelul mucoasei laringiene apar modificări care susțin implicarea refluxului în patogeneză: eritem, edem, ulcerații, granulații la nivelul aritenoizilor şi spațiului interaritenoidian (1,3) .

La nivelul esofagului există bariere fiziologice cu rol protector: sfincterul esofagian inferior, funcția motorie esofagiană cu clearance-ul acid, rezistența tisulară esofagiană şi sfincterul esofagian superior. Mai mult, esofagul prezintă o producție activă de bicarbonat în spațiul extracelular; la nivelul mucoasei laringiene nu sunt prezente toate aceste mecanisme de protecție. În timp ce BRGE apare ca urmare a disfuncției SEI, în FLR este implicată si disfuncția SES. Pacienții cu BRGE experimentează episoadele de reflux mai ales în decubit (noaptea), în timp ce la pacienții cu FLR pH-metria a aratat că cele mai frecvente episoade sunt ziua, în poziție verticală.

Modificările laringiene pot fi cauzate de afectarea directă a mucoasei sau prin mecanisme secundare. Astfel, afectarea directă se datorează contactului acidului şi pepsinei cu mucoasa laringiană, rezultând lezarea mucoasei. Alternativ, iritarea esofagului distal de către acidul gastric, poate cauza un reflex mediat de nervul vag, ceea ce conduce la tuse cronică şi hemaj, cu afectare secundară a mucoasei laringiene (2).

Refluxul biliar poate de asemenea cauza afectare laringiană (1, 3, 4). În plus, descoperiri recente ridică multe întrebări legate de patofiziologia laringitei de reflux. Ekley susține că scăderea factorului de creştere epidermal salivar poate fi asociat cu laringita de reflux. Altman descoperă prezența pompei de protoni la nivelul celulelor seroase laringiene şi a ductelor glandelor submucoase (4,5). Controversele sunt multiple în legatură cu patofiziologia FLR, şi s-a demonstrat că nu este doar o simplă acțiune mecanică a refluxului.

DIAGNOSTIC

Anamneza minuțioasă este importantă, pentru a putea realiza corect un diagnostic diferențial al simptomatologiei. Cel mai frecvent, laringita este o formă uşoară şi se vindecă spontan (5); dacă persistă trebuie definit factorul etiologic probabil: infecții virale sau bacteriene, alergie, abuz vocal, drenaj nazal posterior, leziuni benigne/maligne ale corzilor vocale, FLR. Faptul că

pacientul nu acuză pirozis şi regurgitaţii, nu exclude diagnosticul de FLR.

Asociatia Americana de Bronhoesofagologie (American Broncho-Esophagological Association – ABEA) a prezentat un studiu conform căruia cele mai frecvente simptome de FLR sunt hemajul (98%), tuse cronică persistentă (97%), globus faringeus (95%) şi disfonia (95%). (6)

Belafsky a dezvoltat un chestionar pentru pacienţi, indexul simptomatologiei de reflux (reflux symptom index - RSI) (7), în care pacienţii descriu gradul de severitate pentru disfonie, hemaj, dificultăţi la înghiţire, tuse, senzaţie de corp străin faringian, pirozis, regurgitaţie. Deoarece în studiul statistic efectuat pentru validarea acestui scor, limita de confidenţă la pacienţii din grupul de control, a fost de 13,6 în peste 95% din cazuri, un scor peste 13 este considerat patologic.

Laringoscopia are un rol important în evaluarea laringitei cronice. Modificările clasice pentru laringita de reflux sunt descrise în literatura ca "laringita posterioară", constând în edem şi eritem aritenoidian şi interaritenoidian. (3)

Autorul chestionarului pentru simptomatologia de reflux a dezvoltat şi un scor al modificărilor clinice induse de reflux (reflux findings score - RFS), care cuantifică semnele clinice care pot fi corelate cu prezenta FLR (7, 8). RFS depinde de obiectivarea următoarelor modificări: edem subglotic, obliterare ventriculară, edem al corzilor vocale, edem laringian difuz, hipertrofie a mucoasei laringiene din zona posterioară, granulom sau ţesut de granulaţie, mucoasă endolaringiană îngroşată. Scorul variaza între 0 şi 26, şi o valoare peste 7 are predictibilitate diagnostic de 95% pentru FLR.

Majoritatea pacienţilor (60-70%) cu simptomatologie laringiană de reflux au rezultate normale la endoscopia digestivă superioară, de aceea s-a recomandat utilizarea acestei metode de diagnostic numai la pacienţii care prezintă şi simptomatologie tipică de reflux - pirozis şi regurgitaţii, desi chiar şi la aceaştia, specificitatea metodei este de 83% (1,8).

Monitorizarea pH, deşi a fost considerată investigaţia de bază în multe studii clinice, nu este un instrument de diagnostic ideal; dacă în diagnosticul BRGE specificitatea este de peste 90%, în cazul FLR aceasta este de doar 54-67%, indiferent de localizarea cateterului-esofagian distal, proximal sau hipofaringian. (9-11). Mai mult, monitorizarea pH-ului la nivel esofagian proximal şi hipofaringian nu este o invesţigatie uzuală; în plus, nu există un consens în ceea ce priveşte cantitatea de reflux şi numărul episoadelor de reflux considerate patologice pentru mucoasa laringiană (1,7,9,11).

Impedansmetria esofagiană este superioară pHmetriei, datorită faptului că evidenţiază şi episoadele de reflux nonacid şi gazos; refluxul gazos este frecvent întalnit la nivelul laringelui datorită faptului că gazul are o difuzibilitate mai mare şi astfel poate ajunge la porţiunile superioare ale laringelui şi faringelui (11).

TRATAMENT

Modificările simple şi eficiente ale modului de viaţă sunt esenţiale în controlul simptomatologiei BRGE. Pacienţii trebuie informaţi în legatură cu necesitatea tratamentului de lungă durată, datorită recurenţei şi cronicizării BRGE şi FLR. Modificările stilului de viaţă sunt uşor de explicat şi implementat în tratament, iar costurile socioeconomice sunt scăzute.

Agenţii prokinetici sunt medicamente care cresc presiunea SEI şi accelerează clearance-ul esofagian şi golirea conţinutu-

lui gastric; îndeplinând aceste criterii, sunt teoretic medicamente ideale pentru a corecta mecanismele patogenetice ale BRGE, însă din pacate au numeroase reacţii adverse la nivelul sistemului nervos central şi al sistemului cardiovascular, chiar dacă sunt folosite pe perioade scurte de timp.

Antiacidele ameliorează doar simptomatologia BRGE, fără modificarea clearance-ului esofagian sau a activităţii sfincterelor esofagiene.

Agenţii acid-supresori sunt reprezentaţi de:

- antagoniştii de H2-receptori, care au un singur mecanism de acţiune: inhibarea secreţiei gastrice; nu au nici un efect asupra presiunii SEI sau asupra clearance-ului esofagian.

- inhibitori de pompă de protoni (IPP).

Inhibitorii de pompă de protoni (IPP) reprezintă cel mai eficient tratament nonchirurgical pentru BRGE. IPP (omeprazol, lansoprazol, rabeprazol, pantoprazol, esomeprazol) inhibă enzima H+/K+ ATP-aza care catalizează stadiul final al secreţiei acide în celulele parietale gastrice. IPP au un profil de siguranţă excelent, fără reacţii adverse (altele decât cele observate în studiile efectuate cu utilizare de placebo).

Chiar dacă IPP sunt medicamentele de elecţie în tratamentul BRGE, în FLR raspunsul la tratament este variabil, rata de răspuns variind în literatură între 60 şi 100% (12-15). Aceste studii subliniază variabilitatea răspunsului pacienţilor cu FLR la tratament, necesitatea tratamentului pe o perioadă mai lungă de timp pentru a avea rezultate (mai ales în cazul pacienţilor cu afectare severă), necesitatea unor doze mai mari de IPP, precum şi recurenţa rapidă a simptomatologiei în cazul în care tratamentul este întrerupt, sugerând că tratamentul de lungă durată este deseori necesar la pacienţii cu FLR.

Rata de eşec este mai mare la pacienţii care primesc IPP o singură dată pe zi (13). S-a demonstrat că o doză unică, dimineaţa, îşi menţine efectul antireflux pe o perioadă de doar 13,8 ore (mediana) (13,14). Problema creşterii secreţiei acide nocturne poate fi cauza limitării efectului dozei de seară a IPP (care ar trebui să acopere 10,2 ore) la 7 ½ ore (15). Unii pacienţi au prezentat un nivel normal al secreţiei acide numai după administrarea unor doze crescute de IPP. Nici unul din studiile efectuate nu a reusit să demonstreze că tratamentul cu IPP este o metodă incontestabilă de tratament eficient a FLR, astfel că specialiştii trebuie să fie conştienţi că tratamentul cu IPP nu are eficienţă în toate cazurile.

Deşi există aceste aspecte negative în utilizarea IPP, în lipsa altor metode de tratament rămâne tratamentul de bază pentru aceasta afecţiune. Mai mult, tratamentul cu IPP reprezintă o probă diagnostică în sine, comparabilă cu pH metria şi laringofibroscopia, tînând cont că în studiile clinice specificitatea probei terapeutice este 55-81% (16,17,18).

Tratamentul medicamentos este eficient în controlul refluxului acid în majoritatea cazurilor. Totusi, deşi controlează simptomatologia, tratamentul medicamentos nu corectează modificările mecanice care cauzează refluxul. Mai mult, pacienţii necesită tratament de lungă durată sau pe perioade nedefinite, iar întreruperea tratamentului duce la recurenţe. Indicaţiile tratamentului chirurgical includ simptomatologia persistentă, în pofida managementului medicamentos corect, precum şi intoleranţa pacienţilor la medicamente. Chirurgia este o alternativă şi pentru pacienţii care sunt preocupaţi de costul şi consecinţele unui tratament medicamentos de lungă durată (3, 7, 18).

Algoritmul de diagnostic şi tratament, prezentat în figura 1, reprezintă o modalitate adecvată de abordare a pacienților cu simptomatologie de FLR:

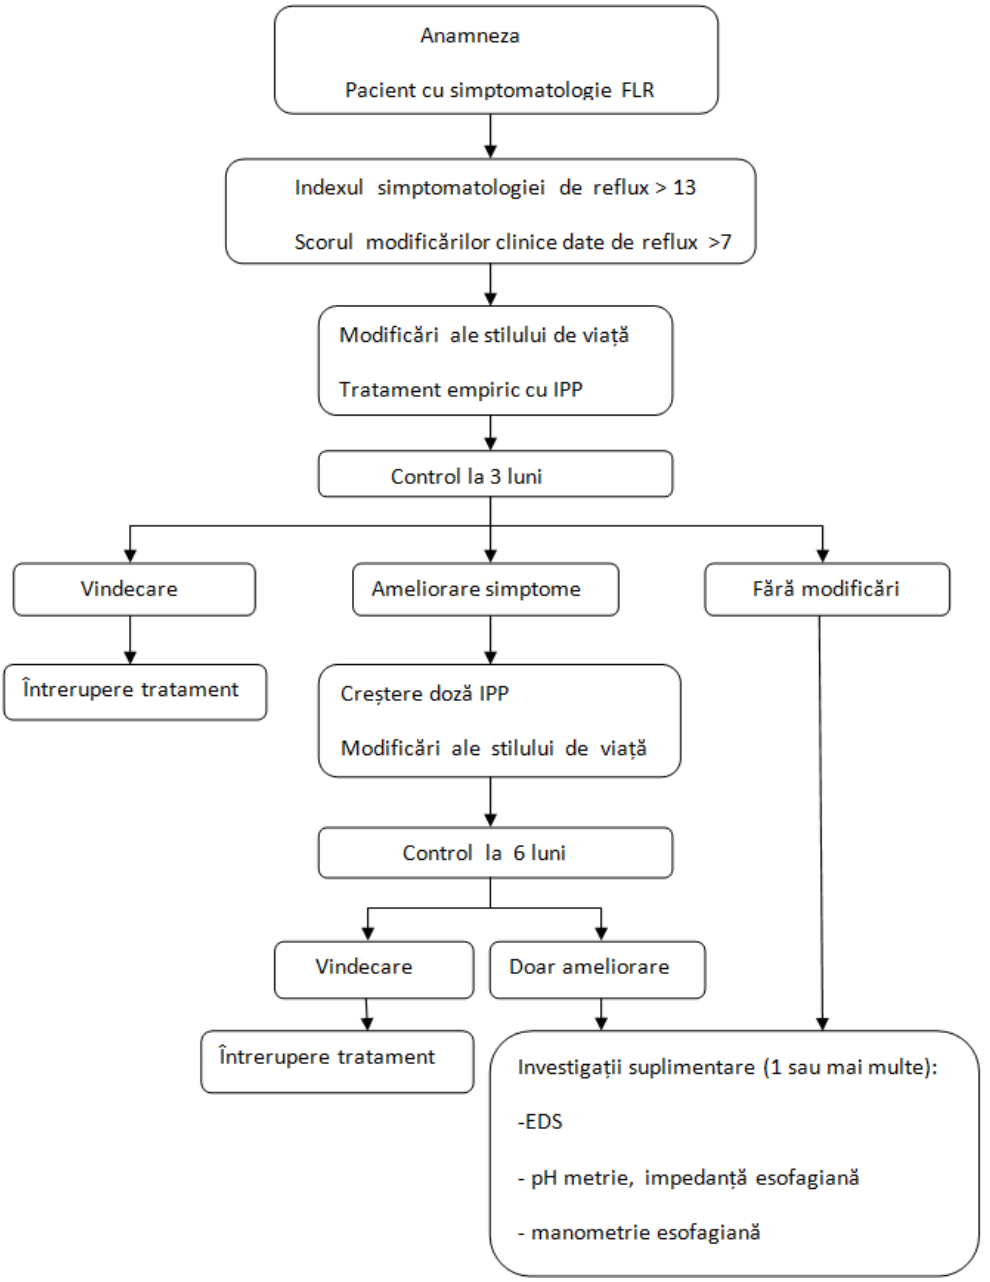

Fig. 1. Algoritm de diagnostic şi tratament pentru FLR (adaptată după Ahmed TF el al,M.Remacle et al) (19,20)

CONCLUZII

La pacienţii cu simptomatologie de FLR, este foarte importantă efectuarea atentă a anamnezei, examenului fizic general si laringoscopiei. Dacă disfagia este prezentă, se va efectua o evaluare endoscopică a deglutiţiei (functional endoscopic evaluation of swallowing – FEES).

Dilema în acest punct constă în efectuarea iniţială a testelor de diagnostic, în principal ph metria, sau în instituirea unei probe terapeutice empirice. Deşi pH metria pare ideală, există totuşi şi limitări: nu este întotdeauna disponibilă, sensibilitatea şi specificitatea nu sunt de 100%, pacienţii nu prezintă episoade de reflux cu aceeaşi frecvenţă în fiecare zi, există variaţii în expunerea la acid a esofagului proximal şi a celui distal, cu riscul de a obţine un studiu ph fals negativ.

Dacă anamneza şi investigaţiile iniţiale (laringoscopia) ridică suspiciunea de BRGE sau FLR, dacă există pirozis sau regurgitaţii (pentru BRGE) sau disfonie, hemaj (pentru FLR), atunci tratamentul antireflux este o alegere adecvată.

Dacă pacienţii nu răspund la acest tratament (IPP x2/zi, 12 săptămâni), se va efectua pH metrie şi se va continua tratamentul antireflux. Absenţa oricărui episod de expunere la acid a mucoasei esofagiene şi prezenţa unei supresii acide gastrice adecvate (pH > 4.5) sugerează că tratamentul medicamentos a fost eficient sau că trebuie cautat alt diagnnostic, dacă simptomatologia nu a disparut, deşi semnele clinice sunt absente. În cazurile în care, după tratament medicamentos, simptomatologia nu se îmbunătăţeşte, se impune efectuarea unor investigaţii suplimentare: impedansmetrie esofagiană, endoscopie digestivă superioară (pentru depistarea unor afecţiuni ca hernia hiatală, esofag Barret, leziuni ale mucoasei esofagiene), transit baritat, manometrie (pentru depistarea unui substrat de dismotilitate esofagiana).

Pacienţii la care simptomatologia de FLR nu se ameliorează semnificativ sau nu se vindecă, dupa tratament medical sau chirurgical, trebuie supravegheaţi pe perioade lungi de timp, datorită posibilităţii apariţiei afecţiunilor maligne.

SFLT-1/PIGF NEW BIOMARKERS FOR MULTIPLE ADVERSE PREGNANCY OUTCOMES (Abstract): Placenta insufficiency and some related pregnancy outcomes are the result of the imbalance between angiogenic and antiangiogenic factors expressed at placenta level. From the angiogenesis factors, only a few have found practical applications, such as the serum soluble fms-like tyrosine kinase-1 (SFlt-1) / PIGF (Placenta growth factor) ratio, named also the angiogenic fraction, which is increased in pregnant women before the clinical onset of a Preeclampsia (PE), intrauterine growth restriction (IUGR) or uterine apoplexy. PROGNOSIS study demonstrated that sFlt-1 / PIGF ratio<38 predicts the absence of PE, eclampsia and HELLP (Hemolysis, Elevated Liver enzymes , Low Platelet count) syndrome within four weeks with a PPV(Positive Predictive value), (95%CI range) of 99.3% (97.9-99.9).Other approaches used different cutoffs for early and late preeclampsia (onset before or after 34 weeks), to enhance the diagnostic accuracy, or included the sFlt-1 / PIGF ratio in a statistical model, along with maternal risk factors, mean arterial pressure (MAP) measurement and uterine artery pulsatility index (UtA-PI), to improve first trimester prediction of PE. Considering the therapeutic applications of angiogenic factors, the use of statins (pravastatin) on animal models to treat PE seems to be promising, as well as the administration of (Vascular endothelial growth factor) VEGF 121 or extracorporeal removal of sVEGF-1.
Keywords: PREECLAMPSIA, ANGIOGENIC PLACENTAL FACTORS, ANTIANGIOGENIC PLACENTAL FACTORS, SFLT-1 / PIGF RATIO.

Placental insufficiency is responsive for many pregnancy pathological conditions as: preeclampsia (PE) (a pregnancy related disease associated with hypertension and proteinuria); uterine apoplexy (UA) or placental abruption (representing early separation of the placenta from the uterus before delivery). These can lead to maternal complications such as: convulsions, disseminated intravascular coagulopathy, hepatic and kidney failure and fetal reserved outcomes such as: fetal growth restriction (FGR), preterm delivery and stillbirth (1).

Placental insufficiency is due to alterations that start during placental development, when vessel formation occurs initially by vasculogenesis followed by branching and nonbranching angiogenesis. Vasculo-

genesis involves de novo formation of blood vessels from mesodermally derived precursor cells, while angiogenesis means new vessels creation from pre-existing vessels (2) and is classified in branching and nonbranching stages.

Branching angiogenesis occurs mainly in the first and early second trimesters and leads to the formation of an immature villous tree. During this phase, a dramatic decrease of the vascular resistance and increase in the blood flow through the placenta is produced by the progressive loss of the musculo-elastic media in the walls of the maternal spiral arterioles. The villous vascular branching adds this process on the fetal side, allowing the maternal and fetal circulations to convert to low resistance high -capacitance vascular bed circulations. Nonbranching angiogenesis stage starts at about 26 weeks of gestation and continues until term. During this phase, a new villous type arises, the mature intermediate villus that is specialized in gas exchange. In this type of villous tree, the tips of the villi are long and slender, and the capillary network creates several loops, the final capillary loop exceeding 4,000 m in length (3). Placentation process requires the involvement of angiogenic growth factors, but also of other molecules such as cytokines, extracellular matrix metalloproteinases, hormones and transcription factors (4). Immunohistochemistry studies shows that human placenta expresses angiogenic growth factors and their receptors, as well as antiangiogenic factors (5).

The angiogenic factors

The expression of angiogenic factors is, itself, regulated by oxygen pressure and mechanical stimuli (5). Placenta insufficiency and some abnormal pregnancy outcomes which derive from this insufficiency, are the result of the imbalance between angiogenic and antiangiogenic factors at the placenta level together with local inflammation.

Different studies described the expression of angiogenic factors at placenta level (2, 5, 6):

- fibroblast growth factor (FGF),
- hepatocyte growth factor, (HGF) and its receptor, c-met,
-vascular endothelial growth factor, (VEGF) and its receptors: VEGFR-1(Flt-1) and VEGFR-2 (flk-1/KDR),
- placenta growth factor (PIGF).

The anti-angiogenic factors

- placenta antiangiogenic factors are represented mainly by serum soluble fms-like tyrosine kinase-1 (s-Flt-1) and soluble endoglin (7).

Angiogenic and antiangiogenic placenta factors: Structure, Expression and Receptor-Binding Properties

Cysteine-knot proteins are a group of structurally related dimeric proteins comprised of eight characteristically spaced cysteine residues with intra- and interchain disulfide bonds between them. PlGF, VEGF(VEGF-A), VEGF-B, VEGF-C, VEGF-D, VEGF-E, and Fos-induced growth factor (FIGF), are the members of said group of growth factors and have in common several biochemical and functional features (i.e. PlGF and VEGF have the ability of forming heterodimeric molecules in the cells where both genes are expressed. VEGF was the first member of the above-mentioned family of growth factors to be identified and isolated. The VEGF-A homodimer exerts its biological activities

through activation of two distinct tyrosine kinase receptors: *fms*-like tyrosine kinase receptor-1 (Flt-1; also known as VEGFR-1) and the kinase domain-containing receptor/fetal liver kinase receptor (KDR/Flk-1; also known as VEGFR-2). Endothelial cells are the main target of this factor, because of their high expression of VEGF receptor-1 (VEGFR-1 or Flt-1) and VEGF receptor-2 (VEGFR-2 or Flk-1/KDR); the effect of VEGF over endothelial cells is to stimulate their proliferation (2, 6).

PlGF is a member like VEGF, more recently identified and described, and has, together with VEGF an important role in the stimulation of endothelial cell growth and, thus, angiogenesis. Placenta growth factor (PlGF), a member of the vascular endothelial growth factor (VEGF) family, is one of the key regulators of pathological angiogenesis, as demonstrated by gene inactivation studies. The PlGF primary transcript gives birth to four forms of the mature PlGF proteins (8) of which PlGF-1 and PlGF-2 (also denominated as PlGF-131 and PlGF-152, respectively), are the predominant forms, which differ in terms of structure by the insertion of a highly basic 21-aminoacid stretch at the carboxyl end of the protein, which consecutively gives the ability of binding to heparin to PlGF-2.

Antiangiogenic factors activated in preeclampsia are: soluble endoglin and sFlt-1(7). Endoglin is a protein that is abundantly expressed in the cell membrane of the syncytiotrophoblastic and vascular endothelium and acts as a co-receptor of transforming growth factor β1 and β3 (TGF-β1 and TGF-β3) (7). In consequence, soluble endoglin acts as an inhibitor to TGF-β1 signaling in the vascular endothelium, resulting in an antiangiogenic effect (18,19). In preeclampsia, soluble endoglin is released into maternal circulation, due to an up-regulation of placental endoglin (8). Circulating soluble endoglin level was shown to increase 2-3 months before onset of PE. Soluble fms-like tyrosine kinase 1 (sFlt 1) is a splice variant of the above-mentioned VEGF receptor, that is lacking cytoplasmic and transmembrane domains, thus acting like an important VEGF and PlGF antagonist (8).

According to one study found in literature, on a rodent model, modest hypertension without significant proteinuria and increased vascular permeability were obtained because of overexpression of soluble endoglin, by means of adenoviral vectors (8). In addition, overexpression of sFlt 1 and endoglin, caused, in a similar fashion, fetal growth restriction and severe vascular damage, nephrotic-range proteinuria, severe hypertension, thus a syndrome like HELLP syndrome (hemolysis, elevated liver enzymes, and low platelets).

In conclusion, endoglin and sFlt 1 are two proteins with similar antiangiogenic effects, obtained through different mechanisms, which may combine producing endothelial dysfunction and severe preeclampsia.

Correlations of angiogenesis with fetal hypoxia

There are three different types of hypoxia that may occur in the fetoplacental unit and may influence fetoplacental angiogenesis: *pre-placental hypoxia, uteroplacental hypoxia and post-placental hypoxia* (5).

1. Pre-placental hypoxia. The mother, the placenta and the fetus are hypoxic, as in pregnancy at high altitude, maternal anemia and cyanotic maternal cardiac diseases. In this condition the peripheral placental villi show increased branching angiogenesis with formation of richly branched but

shorter terminal capillary loops.

2. Uteroplacental hypoxia. In this situation, maternal oxygenation is normal, but the placenta and the fetus are hypoxic, due to an impaired utero-placental circulation. This condition characterizes the preeclampsia with preserved end diastolic flow at umbilical artery.

In this case, the peripheral placental villi show formation of richly branching nests, as in the previous situation, and fetal blood flow is normal or slightly reduced.

Semi-quantitative Western blotting analysis shows in placentae of this type compared to normal placentae, an increased expression of VEGF and reduced expression of PlGF (5), suggesting that placental hypoxia, upregulates VEGF *in vivo* and causes changes in angiogenesis.

3.Post-placental hypoxia.

In this situation, the fetus is hypoxic, whereas the mother is normoxic and the placenta may show higher PO_2 levels than normal, a situation described as 'placental hyperoxia'.

The histopathological analyses show terminal capillaries that are poorly developed and capillary branching that are virtually absent. At ultrasound, the end diastolic flow at umbilical artery is zero or negative.

In this circumstance, the perinatal mortality is around 40% and survivors of neonatal intensive care are at risk of neurodevelopmental handicap. In these cases, PIGF is increased, while VEGF is decreased, suggesting that early onset of placental hyperoxia by enhancing PIGF, induces decrease of branching angiogenesis and failure of terminal villi formation.

Clinical applications of placental angiogenic/antiangiogenic factors

Preeclampsia is an imbalance between pro-angiogenic and anti-angiogenic factors. The ratio sFlt-1/PIGF is elevated in pregnant women before the clinical onset of preeclampsia, and many studies have been conducted, to establish the best sFlt-1: PlGF ratio cutoff to predict the clinical onset of PE in women with risk factors (9).

PROGNOSIS (Prediction of Short-Term Outcome in Pregnant Women with Suspected Preeclampsia *Study*), was a multicenter, prospective, double-blind, non-interventional trial, evaluating the short-term prediction of preeclampsia, eclampsia (maternal convulsions due to complicated PE) and HELLP (hemolysis, elevated liver enzymes, low platelet count) syndrome (PE complicated with hepatic insufficiency and coagulation disorders), in pregnant women with suspected preeclampsia. In this study, more than 1,270 pregnant women were enrolled at 30 sites in 14 countries, between December 2010 and January 2014. Results of the PROGNOSIS study were published by Zeisler *et al.* (10).

This study demonstrated that a ratio of the proteins sFlt-1/PlGF of 38 and below predicts an absence of preeclampsia, eclampsia and HELLP syndrome for one week , with a negative predictive value (i.e., no preeclampsia in the subsequent week) of 99.3% (95% confidence interval [CI], 97.9 to 99.9), whilst an sFlt-1/PlGF ratio above 38 predicts onset of preeclampsia, eclampsia and HELLP syndrome within four weeks, with a positive predictive value of 36.7% (95% CI, 28.4 to 45.7), with 66.2% sensitivity (95% CI, 54.0 to 77.0) and 83.1% specificity (95% CI, 79.4 to 86.3).

In 2013, the same team separated early preeclampsia (onset between 20 and 34 weeks of pregnancy) from late preeclampsia (onset between 34 and 37 weeks of pregnan-

cy). For each of the 2 gestational periods, 2 independent cutoffs framing an equivocal zone were determined: the first cutoff with focus on high sensitivity, and the second focusing on high specificity (11).

Between 20 and 34 weeks, the cutoffs at ≤33 and ≥85 resulted in a sensitivity/specificity of 95%/94% and 88%/99.5%, respectively. After 34 weeks, the cutoffs at ≤33 and ≥110 yielded a sensitivity/specificity of 89.6%/73.1% and 58.2%/95.5%, respectively. The approach to use multiple cutoffs for the early and late preeclampsia phases, enhances the diagnostic accuracy of the sFlt-1/PlGF ratio as a diagnostic tool for hypertensive complication during pregnancy (11).

Some teams, specialized in analyzing different statistical models in the screening of preeclampsia, included biomarkers of angiogenesis (Sflt/PIGF) in a combination of other markers and examined the performance of screening for PE by maternal factors alone and by maternal factors with the addition of each biomarker individually and combinations of biomarkers (12).

Using maternal risk factors, mean arterial pressure (MAP), uterine artery pulsatility index (UtA-PI) and serum placental growth factor (PlGF), this combination could identify, at a 5% false-positive rate (FPR), 98% of cases of early PE, but only 70% and 33% of intermediate and term PE, respectively. Screening at around 32 weeks by a combination of maternal factors with MAP, UtA-PI, PlGF and serum soluble fms-like tyrosine kinase-1 (sFlt-1) could identify, at a 5% FPR, 98% of cases of intermediate PE, but only 54% of term PE (12). PlGF and sFlt-1 levels are simultaneously affected in PE (especially in early pre-eclampsia); thus, the sFlt-1/PlGF ratio represents now a predictor element superior to the individual analysis of these markers.

Another approach in assessing these markers might consist in the sequential determination of serum levels, an approach that has provided better predictive results than the punctual assessment in of the pregnancy a certain moment. The sensitivity of sequential determinations of the sFlt-1/PlGF ratio is of 100% and its specificity is of 98-99% (13).

In the original article, sFlt-1: PlGF ratio, named also "preeclampsia fraction", was performed on Elecsys® Roche Platform (14). The sFlt-1/PlGF ratio is well described and it is a marker for prediction of the PE. Burke *et al*. (14) demonstrated that measurements of PlGF are reliable if we use different techniques and different platforms (R&D Systems, AlereTriage, Roche Elecsys or Abbott Architect).

Future therapeutic uses of angiogenic-antiangiogenic factors

We are waiting for the moment when angiogenic factors will be used as therapy for the prevention of adverse pregnancy outcomes due to placental insufficiency: preeclampsia, uterine apoplexy, fetal growth restriction, in utero fetal death and some cases of preterm delivery. For the moment, there are some promising studies on animals. Sulistyowati *et al*. (15) demonstrated that injection of recombinant VEGF121 has the potential to prevent fetal growth restriction in a newly proposed preeclampsia mouse model (*Mus musculus*).

There are studies on samples of placenta and blood vessels, as well as animal experiments suggesting that statins can reduce the level of abnormalities in angiogenic/anti-angiogenic balance, and perhaps reduce or eliminate the effects and risks of pre-eclampsia. This has been previously

demonstrated in stillbirths of unknown etiology. Statins (HMG CoA reductase inhibitors), seem to positively influence the inflammatory, anti-angiogenic milieu of pregnancies with underlying placental ischemia by their pleiotropic effects. This might prevent, ameliorate and delay preeclampsia (16). Esteve-Valverde *et al*. (17), in a systematic search to summarize the role of statins for preventing and treating severe preeclampsia, found 13 studies about statin's specific use during pregnancy. The review shows a potential beneficial role of statins in preventing and treating severe preeclampsia, meanwhile the rate of major congenital abnormalities in the newborn exposed to statins during pregnancy is no higher than the overall risk population.

Other proposed therapeutic interventions to reverse an anti-angiogenic status during pregnancy include the administration of VEGF 121 or extracorporeal removal of sVEGFR-1(18).

CONCLUSIONS

Our study wishes to be an update concerning the factors of placental angiogenesis and their role in the diagnosis and treatment of preeclampsia and other associated pathologies.

The structure of angiogenesis factors has been known since the '70s, but their clinical applications in placental insufficiency screening and the main obstetric syndromes induced by it, have only emerged in the last few years.

The ratio of variable pro-angiogenic and anti-angiogenic factors characterizes different situations of fetal hypoxia, which could be used in the clinical practice.

DIAGNOSIS IN MENINGITIS: AT THE BORDER BETWEEN MEDICINE AND COMPUTER SCIENCE

We all live in a world marked by the stamp of technology and information. In these circumstances, the biggest challenge for the information era is to establish some diagnoses using only computer science, without the help of human mind. In other words, the final goal is to develop performing programs which can diagnose a disease using just a set of parameters. For the first time, the researchers developed an original method that can differentiate between bacterial and viral meningitis. This is based on the DRSA methodology and it is constituted by a set of decision rules, like "if…then...". The method had results with a coverage factor between 2 and 95% and this can maintain the interest on the topic. Although the establishment of the diagnosis by computer seems to be utopian at this moment, this study opens the gate of a new universe of research with big chances of feasibility and practicability in future medicine (Gowin E, Januszkiewicz-Lewandowska D, Słowinski R, Błaszczynski J, Michalak M, Wysocki J. With a little help from a computer: discriminating between bacterial and viral meningitis based on dominance-based rough set approach analysis. *Medicine* 2017; 96: 32(e7635).

2. Spitalul General CF Galaţi
Spitalul Clinic Judetean de Urgenţe "Sf. Spiridon" Iaşi
3. Clinica a III-a Chirurgie

STROMAL TUMORS OF JEJUNUM AND ILEUM (Abstract): Gastrointestinal stromal tumors (GIST) are the most common mesenchymal tumors of the digestive tract and 25% are in the small intestine. **Material and method**: A retrospective study was performed on 73 patients diagnosed with intestinal cancer in three hospitals in Iasi and Galati, in a period of 12 years (1998-2009). **Results:** Stromal tumors represents 11.5% of malignant tumors of jejunum and ileum, and the average age of diagnosis was 55 years; male to female incidence was 1:2 ($\chi^2 = 0.66$, $p > 0.05$). 66.66% of patients came from urban areas ($\chi^2 = 0.66$, $p > 0.05$). The most frequent signs and symptoms were abdominal meteorism and abdominal pain (83%). There were no correlations between admission and discharge diagnosis. CD117 was present in all patients; CD34 was present in 66.66% of them. Survival at 2 years was 66.67% and at 5 years was 33.33%. **Conclusions:** Preoperative diagnosis is often difficult to make, many patients come to doctors in advanced-stage and the five-year survival rate is slow. The most frequent tumor markers were CD117 and CD34. **Key words:** GASTROINTESTINAL STROMAL TUMORS, SMALL BOWEL, IMMUNOHISTOCHEMISTRY

Tumorile stromale gastro-intestinale (GIST) sunt cele mai frecvente tumori de origine mezenchimală de la nivelul tubului digestiv. Intestinul subţire reprezintă al doilea sediu al tumorilor stromale, după stomac, 25% dintre ele apărând la acest nivel. Tumorile stromale intestinale reprezintă doar 14% din totalul tumorilor intestinului subţire (1). Vârsta medie de diagnostic este de 58 de ani (1,2,3).

Diagnosticul de certitudine se bazează pe examenul anatomopatologic şi pe testele de imunohistochimie (1).

Ca şi în cazul altor tumori ale intestinului subţire, datorită simptomatologiei fruste şi nespecifice, diagnosticul de tumoră stromală de intestin subţire se pune tardiv, în stadii avansate ale bolii (5) .

Supravieţuirea la 5 ani este de 30-60% în funcţie de stadiul tumorii la momentul diagnosticului (6,7,8,9).

MATERIAL ŞI METODĂ

A fost efectuat un studiu retrospectiv pe un număr de 73 de pacienţi diagnosticaţi cu tumori intestinale într-o perioadă de 12 ani (1998-2009) la Spitalul Clinic „Sf. Spiridon" Iaşi, Clinica III Chirurgie, Spitalul Judeţean Galaţi şi Spitalul General Căi Ferate Galaţi. 71,23% dintre pacienţi au fost diagnosticaţi cu tumori maligne, iar 28,76%, cu tumori benigne.

Tumorile stromale de jejun şi ileon au fost studiate din punct de vedere epidemiologic, imunohistochimic şi a manifestărilor clinice.

Pentru prelucrarea statistică a datelor s-a folosit *„Statistical Package for Social Sciences"* (*SPSS*) şi s-au folosit metode sta-

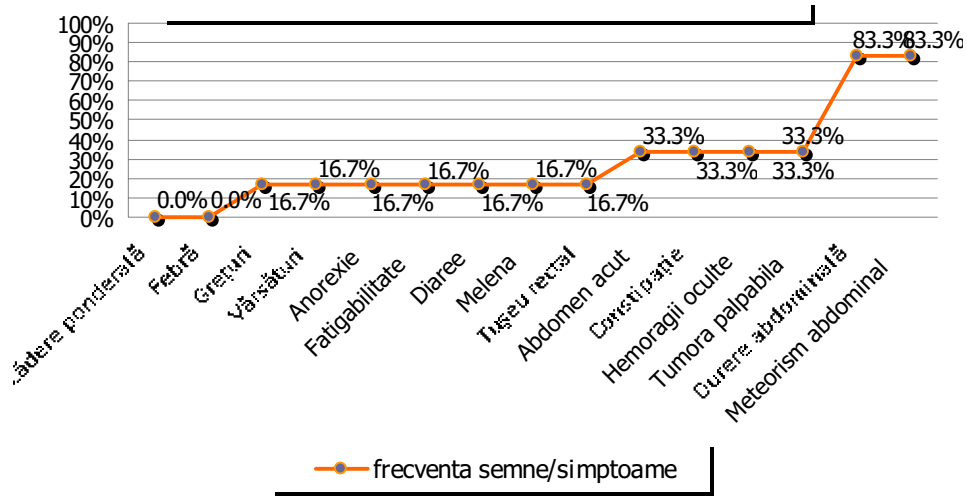

Fig. 1. Semne şi simptome ale tumorilor stromale de jejun şi ileon

tistice descriptive, cât şi metode care se încadrează în statistica inferenţială.

REZULTATE

Tumorile stromale au reprezentat 11,5% din totalitatea tumorilor maligne, iar vârsta medie de diagnostic în lotul studiat, a fost de 55 de ani. Raportul între subiecţii de sex masculin şi cei de sex feminin a fost de 1:2, (χ^2 = 0,66, p > 0,05). Sexul pacienţilor nu a influenţat frecvenţa tumorilor stromale, valoarea lui χ^2 (mai mică decât valoarea 3,84 din tabelul lui Fisher) determinându-ne să acceptăm ipoteza de nul.

Din punct de vedere a mediului de provenienţă, 33,33% din pacienţii cu tumori stromale de jejun sau ileon provin din mediul rural, iar 66,66% din mediul urban (χ^2 = 0,66, p > 0,05). Valoarea lui χ^2 de 0,66 cu un p > 0,05 semnifică că nici variabila mediul de provenienţă al pacienţilor nu a influenţat frecvenţa tumorilor stromale.

În acest studiu, toate tumorile stromale au fost localizate la nivelul ileonului. Localizarea tumorilor stromale pe ileon sau jejun nu a fost influenţată de sexul pacienţilor. Valoarea lui χ^2 (cu un prag de semnificaţie mai mare de 5%) pentru localizarea pe ileon, semnificând faptul că nu există o diferenţă semnificativă din punct de vedere statistic.

Cele mai frecvente semne şi simptome întâlnite la internare au fost: meteorismul abdominal şi durerea abdominală care se regăsesc în 83,3% din cazuri, iar hemoragiile oculte, tumora palpabilă, constipaţia şi abdomenul acut au avut fiecare o frecvenţă de 33,3%. Nu s-a înregistrat nici un caz cu febră sau scădere ponderală (fig. 1).

Examenele paraclinice efectuate au fost: ecografia abdominală de care au beneficiat toţi pacienţii şi care a identificat o formaţiune tumorală abdominală în 66,66% din cazuri; radiografia abdominală pe gol, s-a efectuat la 33,33% dintre subiecţi şi a constatat prezenţa nivelurilor hidro-aerice în 50% dintre aceste cazuri, iar computerul tomograf a fost efectuat în 16,66% din cazuri şi a fost pozitiv în toate situaţiile.

Cele mai frecvente diagnostice puse la internarea pacienţilor cu tumori stromale au fost de abdomen acut chirurgical şi sindrom dureros abdominal.

Concordanţa între diagnosticul de internare şi cel de externare a fost 0. Diagnosticele de internare au fost: abdomen acut chirurgical 33,33%, sindrom dureros abdominal, apendicită acută, ocluzie intestinală

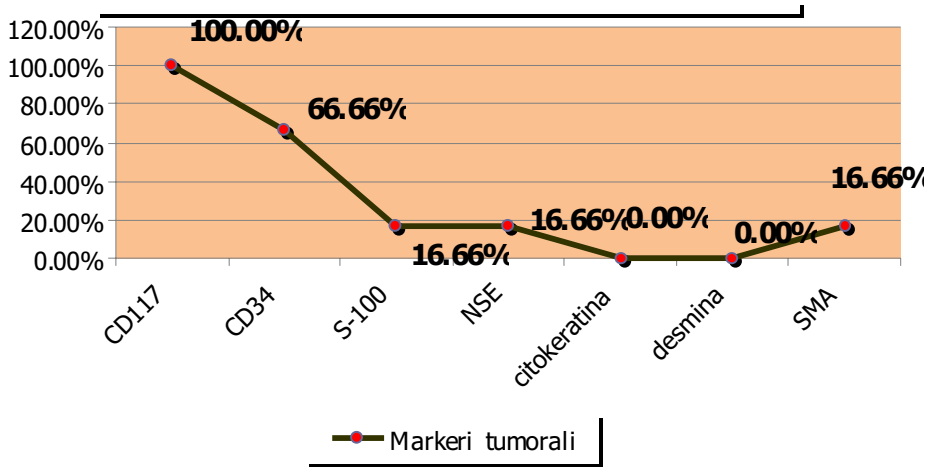

Fig. 2. Frecvenţa marcherilor tumorali pentru pacienţii cu tumori stromale de jejun şi ileon.

şi tumoare ovariană, fiecare reprezentând 16,66%.

Din punct de vedere imunohistochimic, CD 117 a fost prezent la toţi pacienţii luaţi în studiu şi care au fost diagnosticaţi cu tumoră stromală, CD34 în 66,66% din cazuri, S-100, NSE (neuron specific enolase) şi SMA (actina specifică muşchiului neted), în 16,66% din situaţii. Citokeratina şi desmina deşi au fost determinate, nu au fost evidenţiate în nici un caz (fig.2).

33,33% dintre pacienţi au prezentat metastaze ganglionare la momentul diagnosticului, iar 16,66% au prezentat metastaze la distanţă. Cei cu metastaze la distanţă nu au supravieţuit la 5 ani, spre deosebire de cei cu metastaze ganglionare, care au supravieţuit la 2 ani, dar nu şi la 5 ani.

Supravieţuirea la 2 ani a fost de 66%, iar la 5 ani de 33%. În ambele situaţii raportul între pacienţii de sex feminin şi cei de sex masculin, cât şi între mediul urban şi cel rural, a fost de 1 : 1.

Pentru subiecţii care au supravieţuit la 2 ani, toţi au avut CD117 prezent, iar CD34 a fost prezent în 60% din cazuri. Ceilalţi marcheri tumorali au fost absenţi. În cazul pacienţilor care au supravieţuit la 5 ani, doar CD117 a fost prezent.

DISCUŢII

Pentru tumorile stromale, intestinul subţire reprezintă al doilea sediu ca frecvenţă, după stomac.

În acest studiu, ele au reprezentat 8,3% din totalul tumorilor intestinale, procent care este în concordanţă cu studiile anterioare (1).

Vârsta medie de diagnostic a acestor tumori este, conform literaturii de specialitate, de 58 de ani (1,10,11). Studiul actual a obţinut o vârstă medie de diagnostic de 55 de ani şi un raport de 1 : 2 între subiecţii de sex masculin şi cei de sex feminin, spre deosebire de alte loturi studiate la care vârsta medie de diagnostic a fost de 60 de ani, iar numărul pacienţilor de sex feminin a fost egal cu a celor de sex masculin (12).

66% dintre pacienţii diagnosticaţi cu tumoră stromală, au provenit din mediul urban. Acest fapt poate fi explicat prin modul de alimentaţie, care în mediul urban este mai bogat în aditivi alimentari, dintre care unii s-a dovedit că sunt implicaţi în apariţia cancerului la nivelul intestinului subţire (13, 14,15).

S-a constatat că cele mai frecvente semne şi simptome apărute la prezentarea la medic au fost meteorismul abdominal şi durerea abdominală, iar cel mai frecvent diagnostic

de internare a fost abdomenul acut chirurgical, rezultate care sunt în concordanţă şi cu alte studii (12).

Examinările paraclinice cele mai relevante în cazul tumorilor stromale de jejun şi ileon sunt computer tomografia (CT) şi rezonanţa magnetică nucleară (RMN) (16, 17), CT-ul dând un diagnostic de certitudine şi în cazurile studiate de noi.

CD117, a fost prezent la toţi pacienţii, iar CD34 la 66% dintre aceştia. CD 117 este expresia lui c-kit în cazul tumorilor stromale gastrointestinale (GIST), fiind considerat ca principalul marcher pentru GIST, iar CD34, este un marcher nespecific, dar destul de frecvent întâlnit în tumorile stromale, între 47% până la 70% din cazuri (18).

Alţi marcheri, cum ar fi SMA, NSE şi S-100 sunt întâlniţi mult mai rar.

Prezenţa CD117 şi CD34 la pacienţii care au supravieţuit la 2 ani, poate fi explicată prin frecvenţa crescută a acestor markeri în momentul diagnosticului de tumoră stromală.

Supravieţuirea la 2 ani a fost de 66% iar la 5 ani de 33%. Supravieţuitorii la 5 ani nu au prezentat metastaze şi au beneficiat de rezecţie completă a tumorii.

Compararea ratelor de supravieţuire din diferitele studii publicate este dificil de realizat deoarece nu există un sistem standardizat de stadializarea a GIST iar multe studii sunt alcătuite dintr-un număr mic de subiecţi heterogeni. Cu toate acestea, s-a constatat o supravieţuire la 5 ani de 32-93%, în cazul rezecţiilor tumorale complete şi doar de 10% pentru situaţia în care tratamentul a fost paleativ (19).

CONCLUZII

Diagnosticul de tumori stromale de jejun şi ileon este dificil de pus preoperator, cei mai mulţi pacienţi prezentându-se la medic în stadii avansate. Vârsta medie de diagnosticare a fost de 55 de ani. Cei mai frecvenţi marcheri tumorali au fost CD117 şi CD34. Supravieţuirea la 2 ani a fost de 66%, iar la 5 ani de 33%.

DETERMINATION OF GRADE OF GASTROINTESTINAL INJURY AND ITS PROGNOSTIC UTILITY IN PATIENTS WITH ACUTE NECROTIZING PANCREATITIS (Abstract): Acute necrotizing pancreatitis (ANP) is potentially lethal inflammatory process. Recent researches established that presence of multiorgan failure together with pancreatic infection are major determinants of its mortality. But significance of acute gastrointestinal injury (AGI) in course of ANP is still remaining unclear. **Aim:** To determine frequency and significance of AGI on severity and mortality of ANP. **Material and methods:** We performed a prospective observational cohort study of 151 patients with ANP which were admitted to single intensive care department. AGI was established according to European Society of Intensive Care Medicine (ESICM) recommendations. Clinical and laboratorial variables as well as plasma citrulline concentrations were studied. **Results:** Persistent organ failure was diagnosed in 33% and transient in 67% observations. Respiratory failure has been dominated in mortality structure, cardiovascular, renal and intestinal failures were met with equal frequency. Serum citrulline concentration reflected the level of AGI. **Conclusions:** Intestinal failure is strongly associated with unfavorable events in patients with acute necrotizing pancreatitis as well as pulmonary, cardiovascular and renal dysfunctions. Plasma citrulline concentration is simple and reliable marker for diagnosing and monitoring AGI. **Keywords:** ACUTE NECROTIZING PANCREATITIS, GASTROINTESTINAL DYSFUNCTION, CITRULLINE.

Acute necrotizing pancreatitis (ANP) is a surgical disease caused by primary aseptic necrosis of the pancreatic tissues, accompanied by the development of systemic inflammatory response syndrome in both aseptic and infected necrosis. In recent years there has been a significant increase in the number of patients with infected forms of ANP and the development of infected complications whose mortality reaches 17-70% (1). Assessment of the severity of the attack and predicting the course of the disease are important when determining the allocation of care for these patients or the need for transfer to a higher-level care early in the disease process. Recent researches established that presence of multiorgan failure together with pancreatic infection are major determinants of mortality during ANP (2-4). The mortality rates in the absence of organ failure, in the presence of one organ failure, and in pa-

tients with multi-organ failure are 0%, 3%, and 47%, respectively (5-6). The gastrointestinal system is considered critical to the development of organ failures, with bacterial translocation in intensive care unit patients supporting the concept of the gut having a role in multiorgan failure (7). In critically ill patients, the intestine is a vulnerable organ, and gastrointestinal dysfunction is common. It has been reported that almost 50% of patients in intensive care units (ICUs) have enterocyte damage at admission (8). It is therefore important to monitor the status of the GI tract in critically ill patients. In 2012, the Working Group on Abdominal Problems of the European Society of Intensive Care Medicine (ESICM) defined acute gastrointestinal injury (AGI) as the malfunctioning of the gastrointestinal tract in critically ill patients due to their acute illness and recommended a four-grade classification for AGI severity (9). However, this definition mainly depends on the symptoms and signs of AGI, which are usually not sufficient to objectively determine its severity and impact on patients' prognosis.

MATERIAL AND METHODS

This prospective observational cohort study was performed at Regional Emergency Hospital, Chernivtsi, Ukraine, between March 2010 and September 2017. The study was conducted in accordance with the principles of the Declaration of Helsinki. The ethics review board of each participating hospital approved the study. Patients or their legal representatives gave written informed consent. During this period 708 patients with acute pancreatitis were admitted to clinic. Patients were included in the current prospective study if they fulfilled the inclusion criteria of signs of pancreatic necrosis on contrast-enhanced computed tomography. Necrosis was diagnosed by lack of pancreas enhancement on contrast computed tomography, which was a sign of impaired or absent tissue perfusion. There were 192 cases of ANP. Patients were not enrolled to the study if any of the following criteria were present: a) age < 18 and > 80 years; b) recent surgical interventions; c) psychoses; d) pregnancy; e) previously history of chronic pancreatitis. After exclusion of abovementioned cases we enrolled to current study 151 patients with ANP. All of them were admitted to single intensive care department.

Severity of ANP was determined according to the recently revised Atlanta Classification (10). Organ failure was defined for respiratory, cardiovascular, and renal system by modified Marshall scoring system 10. Besides above organs dysfunction of neurological system, liver and intestine were estimated. Neurological failure was established by Glasgow coma score. Hepatic dysfunction was evaluated according to Child-Pugh classification (11), grade B or C were criteria for diagnosis of liver failure. AGI was estimated by European Society of Intensive Care Medicine recommended four-grade classification (grades I, II, III, and IV). Only 3rd and 4th grade of AGI was recognized as intestinal failure. Intra-abdominal pressure was measured via the bladder, with patients in the supine position, using the closed loop system repeated measurements technique (12). Additionally, venous blood citrulline concentration was determined as indicator of intestinal epitheliocytes functional activity (13). After admission, patients received fluid resuscitation, and full laboratory investigations were performed on the first 3 days and in the 24 hours before any inter-

vention. Nasojejunal enteral feeding was initiated if an oral diet was not tolerated after 48-72 hours after admission. If there were problems with nasojejunal intubation nasogastric tube feeding was started. Parenteral nutrition was only initiated when oral route was not tolerated or sufficient, but at least small amount of enteral feeding was present in all patients. In line with international guidelines, intervention was generally only performed in case of suspected or confirmed infection of pancreatic necrosis or peripancreatic necrosis alone. The decision to intervene was mostly based on clinical grounds (i.e. deterioration). Whenever possible, intervention was postponed until approximately four weeks after the onset of disease. In case of proven or suspected infection of pancreatic necrosis within four weeks after onset of disease, antibiotics were administered, and intervention was postponed as long as possible.

The following parameters were collected for each episode of acute necrotizing pancreatitis: length of hospital stay, in-hospital mortality, presence of organ failure, and local complications such as acute peritoneal fluid collection, pseudocyst, acute necrotic collection and walled-off pancreatic necrosis. Acute Physiology and Chronic Health Evaluation (APACHE)-II, Marshall scores, presence of organ failures and systemic inflammatory response syndrome (SIRS) were calculated daily during period of ICU treatment.

Statistics data were collected in a Microsoft Excel database. After completion of data collection, the database was imported into SPSS for Windows (SPSS 16.0., Chicago, IL, USA). Continuous variables were expressed as mean with standard deviation and compared using Student's t- test or Mann–Whitney test. Categorical variables were expressed as absolute numbers and proportions. Pearson's $\chi 2$ test or Fisher's exact test was used for comparison of categorical variables. Logistic regression models were created to analyze the independent effects of organ failures on mortality. To define predisposing factors, the odds ratio and its 95% confidence interval were used as a binary parameter. Receiver Operator Curve (ROC) was generated to determine cutoff value of citrulline for estimation of intestinal failure. A p value of < 0.05 was considered statistically significant.

RESULTS

Different levels of AGI were diagnosed in 141 (93.37%) of patients with ANP.

The 1st grade of AGI (risk of intestinal dysfunction) was detected in 37 (24.5%) cases. The general condition of patients was stable, with no organ failure, assessed according to the APACHE II scale from 6 to 9 points. Intestinal paresis, nausea, reflux, or vomiting were of a temporary nature and quickly passed by themselves, without affecting the general condition of the patients. IAP was within the range of 5-12 mmHg, citrulline in blood plasma – 28-38 μmol/L.

The 2nd grade of AGI (gastrointestinal dysfunction) was found in 54 (35.8%) persons. The general condition of patients was of moderate severity, assessed according to the APACHE II scale from 10 to 19 points. Patients demonstrated clinical signs and laboratory parameters of transient organ failure, which was corrected within 24-48 hours after hospitalization. Intestinal dysfunction was manifested by the acute development of intestinal paresis, large (more than 500 ml) residual volume of the stomach, reflux, intra-abdominal hypertension of the 1st stage (IAP was within the range

of 12-14 mmHg). Citrulline in blood plasma was lower than the index in the control group and equaled to 16.57±0.48 μmol/L ($p<0.01$).

The 3rd grade of AGI (intestinal failure) lasting more than 3-5 days was detected in 38 (25.2%) patients, whose condition severity was assessed according to the APACHE II scale from 19 to 30 points. There has been detected prolonged pronounced paresis of the intestine (caecum dilatation up to 9 cm, colon dilatation – up to 10 cm), high residual volume of the stomach (from 500 to 1,000 ml), progression of intra-abdominal hypertension (15 to 20 mmHg), accompanied by a low level of the abdominal cavity organs perfusion (perfusion pressure was less than 60 mmHg), in particular of the intestine and pancreas, leading to the development of persistent organ failure. Acute respiratory failure, renal failure and circulatory disorders were the most common. In accordance with the patients' condition severity and the intestinal dysfunction stage, the citrulline concentration in blood plasma decreased to 11.03±0.19 μmol/L.

The 4th grade of AGI with severe impact on the distal organs (critical intestinal failure) developed in 12 (8.0%) patients with severe ANP, whose general condition was assessed according to the APACHE II scale from 25-30 to more points. Their citrulline level dropped till 10.54±0.86 μmol/L. Later on, increase in the intra-abdominal pressure to 25-30 mmHg was accompanied by the development or deepening of existing permanent organ failure and is characterized as abdominal compartment syndrome. The abdomen is bloated, the abdominal wall is tense and painful when palpated, intestinal peristalsis is often not auscultated, there occurs reflux of gastric content or vomiting, residual volume of the stomach is more than 1,000 mL, dilatation of the caecum and colon is more than 12 cm. First of all, respiration is impaired, and patients need respiratory support already at the initial stage of ACS. The direct effect of high IAP on the lower hollow vein leads to a decrease in blood flow to the heart and, accordingly, cardiac output reduces (tab. I).

TABLE I

Grade of acute gastrointestinal injury in patients with acute necrotizing pancreatitis

AGI grade	Number of patients (%)	APACHE II score	IAP (mm Hg)	Citrulline (μmol/L)	Mortality, n (%)
0	10 (6.60)	6.30±0.11	7.50±0.11	32.1±0.29	- (0)
1st	37 (24.5)	8.10±0.13	9.80±0.13	24.5±0.25	- (0)
2nd	54 (35.8)	14.4±0.23	13.1±0.17	16.6±0.48	5 (9.30)
3rd	38 (25.2)	22.3±0.32	16.7±0.28	11.7±0.19	15 (39.5)
4th	12 (8.00)	27.5±0.16	23.5±0.31	10.5±0.86	11 (85.7)

The citrulline level below 12.5 μmol/L allowed to diagnose intestinal failure with the sensitivity of 90.4% and specificity of 84.6% (AUC ROC 0.905±0.0179, $p=0.001$) (fig. 1). A reliable correlation dependence between the grade of AGI and citrulline concentration in the blood ($r=0.743$ $p<0.05$) has been identified. Overall mortality rate was 20.5% and observed only among persons with severe form of ANP.

A number of organs with dysfunction were significantly higher in deceased pa-

tients compared with survivors (3.48±0.81 and 1.33±0.44, respectively, $p<0.05$) as well as APACHE II score, age, hematocrit and creatinine level.

Respiratory failure had been dominated in mortality structure, cardio-vascular, renal and intestinal failures were met with equal frequency.

Failures of these organs were independent factors of mortality in multivariate logistic regression model (Wald's criteria 8.441, 5.464, 5.660 and 3.847, accordingly, $p<0.05$). Neurological and liver failures did not influence on patient's survival (tab. II).

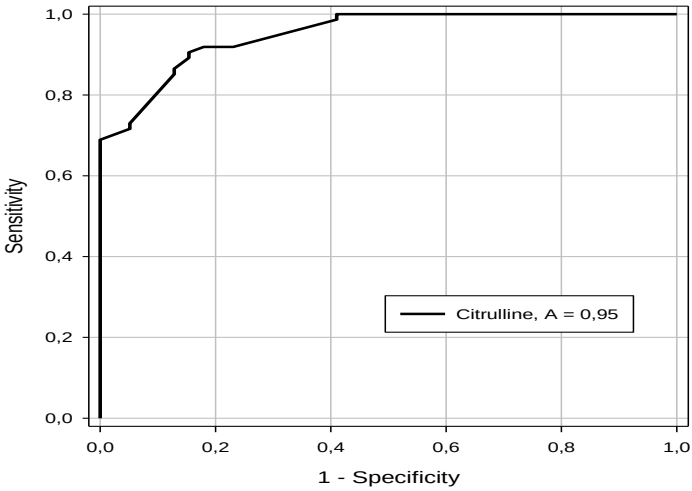

Fig 1. ROC curve of intestinal failure diagnosis by citrulline

TABLE II

Influence of organs failure on survival of patients with acute necrotizing pancreatitis

Factors	Deceased (n=31)	Survived (n=120)	p value
Respiratory failure, n (%)	28 (90.4%)	31 (25.8%)	0.001
Cardiovascular failure, n (%)	25 (80.6%)	11 (13.3%)	0.001
Neurological failure, n (%)	11 (35.5%)	26 (21.7%)	0.111
Renal failure, n (%)	25 (80.6%)	28 (25.0%)	0.001
Liver failure, n (%)	8 (25.8%)	22 (18.3%)	0.353
Intestinal failure, n (%)	24 (77.4%)	26 (21.7%)	0.001
Multiorgan failure, n (%)	28 (90.4%)	30 (25.0)	0.001

DISCUSSION

In our study respiratory failure occurred most frequently in patients with severe ANP and was followed by cardiovascular, renal and intestinal failures, which have similar impact on mortality

rate. Recommended by 2012 Atlanta classification committee modified Marshall score as well as other widely accepted organ failure scores like SOFA, MODS, APACHE II are dealing with respiratory, cardio-vascular and renal failures but missing intestinal dysfunction. Evaluating the intestine is difficult for two reasons: it is a deep organ, far from the mouth, anus, and abdominal wall, and critically ill patients are frequently not able to inform clinicians about a digestive complaint. This explains why its dysfunction may sometimes be occult or misdiagnosed, and the fact that it is not clearly integrated into the overall approach used to treat intensive care unit patients. However, even occult small bowel dysfunction may have clinical consequences on patient prognosis. The gut hypothesis of multiple organ failure was first put forward more than 20 years ago (7). According to this hypothesis, the multisystemic disorders defining this syndrome could be the late consequences of a previous small bowel injury. If the intestinal failure could be evaluated and protected on admission, gut-related sepsis will be reduced, and the mortality rate will fall down. Reintam Blaser *et al*. (9) found that 59% of critically ill patients have at least one gastrointestinal symptom during their stay in the intensive care unit. In 2012, The Working Group on Abdominal Problems of the ESICM has developed the definitions for gastrointestinal dysfunction in intensive care and proposed AGI score which was based on presence of feeding intolerance and intraabdominal hypertension. However, despite a welcome contribution to assessing AGI, it was noted that feeding intolerance was a subjective measurement, and that intraabdominal hypertension was not specific to gastrointestinal dysfunction (19). Although the AGI score proposed by ESICM appeared to be a new prognostic tool to evaluate critically ill patients, it was not based on a pathophysiological model of gastrointestinal dysfunction. We chose to examine changes of citrulline concentration as a marker of enterocyte mass in patients with acute necrotizing pancreatitis. This amino acid is synthesized exclusively by small intestinal mucosal epitheliocytes thus it may serve as a measure of intestinal mucosal functional activity (14). Recently it was established that plasma citrulline concentrations were able to reflect enterocyte mass in various small intestinal diseases including coeliac disease (15), short bowel syndrome (16), radiation enteritis (17) and Crohn disease (18).

In our research citrulline level decreased 1.5 times in patients with moderately severe pancreatitis and 3 times ($p<0.05$) in patients with severe form, which was highly inverse correlated ($r = -0.643$, $p<0.05$) with clinical AGI score. In deceased persons its concentration dropped less than 10.31±0.42 μmol/L, indicating critical level of intestinal failure due to deep injury of mucosal villi, desquamation of intestinal epithelia and high rate of bacterial and endotoxin translocation.

CONCLUSIONS

Acute gastrointestinal injury occurs in 93.4% of patients with ANP and appears as intestinal dysfunction in 35.8% and failure in 33.2%.

Intestinal failure as well as respiratory, cardiovascular and renal are independent factors of mortality at ANP.

Serum citrulline concentration below 12.5 μmol/L is simple and reliable marker for diagnosing of intestinal failure.

THE THREE-DIMENSIONAL ULTRASONOGRAPHY OF THE FETAL FACE – HISTORY AND PROGRESSES

C. Mărginean, Klara Brînzaniuc, Gh. Mühlfay, Karin Horvath, Oana Mărginean
University of Medicine and Pharmacy Târgu Mureş
School of Medicine

THE THREE-DIMENSIONAL ULTRASONOGRAPHY OF THE FETAL FACE – HISTORY AND PROGRESSES (Abstract): Fetal face was the main concern of researchers who developed three-dimensional ultrasound. 3-D ultrasound beginnings date back to 1973. Parallel concerns of researchers from different parts of the world have led to a constantly changing the equipment and software. 3-D images of the fetal face were obtained since 1986, but those that are available on the ultrasound devices sold today dates from 1992, and the 4D since 1996. Techniques such as volum rendering and multiplanar volume rendering, led to the development of 3D ultrasound. Late 2000 revealed study fetal face by multiplane three-dimensional ultrasound, through the acquisition of volume and its processing. Study of fetal profile by this method provides new data on the jaw, naso-maxillo-mandibular angle, even a diagram of the fetal profile or of dimensions of the fetal face or nasal bone length. Fetal profile analyzed by 16 parameters measured by 3D ultrasound, with the creation of a craniofacial index variable is useful in assessing normal and abnormal fetal face. Today, the bones of fetal face - nose, jaw, bone palace, those of the orbit, can be studied in dynamics, from 12-14 gestational weeks. The best ultrasound images can be obtained after 21 gestational weeks, when fetal size and its ratio with amniotic fluid are optimal for the acquisition of fetal volume. **Key words**: 3D ULTRASOUND, FETAL FACE, HISTORY

A 3D fetus visualization has always been a concern for many investigators, including Tom Brown in Glasgow at the beginning of 1970 who made a"multiplan" scanner, in 1973, working for Sonicaid Ltd. (1). Starting with achievements in ultrasonography and computerised technology, the possibility of three-dimensional visualization appeared, at the beginning of 1980.

Kazunori Baba from the Institute of medical electronics, The University of Tokio, Japan, was the first who had reported a 3D ultrasonography system in 1984 and managed to get 3D fetal images, processing the 2D images on a mini-computer in 1986 (2,3). In 1992 Baba published, in Japanese, the first book of ultrasonography in obstetrics and gynaecology, a book which also contained chapters about the 3D ultrasonography (1,4,5).

In 1990, another group from the University Columbia led by Donald King, described other approaches and algorithms for the 3D spatial registrations and the visualization of ultrasonographic position and orientation of the images forreall (1,6).

In 1992, the team from the National University Hospital Cheng Kung of Taiwan, Chinese Republic, reported a 3D visualization of the fetal face, cerebellum and the spine, using a Combison 330. In 1994, Olaf von Ramm, Stephen Smith and his team, made an improved scanner which ensured a good resolution, up to 20 cm. The team has developed a *"state of the art"* of ultrasonographic medical images, being able to process signals from multiple sections, forreal (1). On the market it has been available since 1997.

Fig. 1. Fetal face obtained through surface rendering technique, with further acquisition of the volume processed in the following images (21 weeks' pregnancy)

In 1993, Wilfried Feichtinger from the University of Vienna, presented images with 10 weeks embryoes using the 3D transvaginal transducer. Alfred Kratochwil continued to support the development of 3D technology, and after retiring he continued to teach 3D ultrasonography. The group Urlike Hamper presented images with different congenital malformations using a 3D prototype scanner (1). În 1996, The group Nelson and the one from the medical imagistics of the University Hospital of London published independent researches on fetal echocardiography in 4D (3D in movement) (7,8,9).

In 1995, Eberhart Merz from the centre of ultrasonic diagnosis and prenatal care of the Mainz University, Germany, proved the utility of multiplanar orthogonal images and also the surface visualization and the transparent ones, in the diagnosis and confirmation of the fetal surface and the skeletal abnormalities, for example the cleft lip or multiple complex malformations (1,4). He and his contributors reported a great

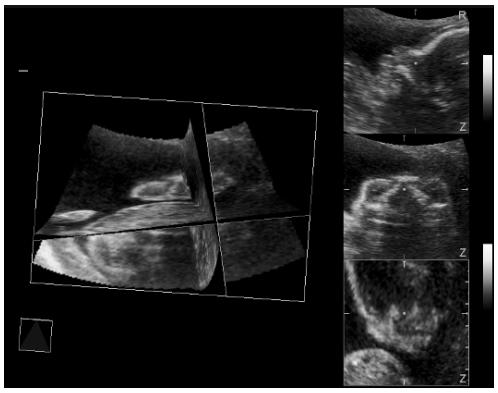

Fig. 2. The obtained and processed volume with the 3 slice technique. There can be seen the 3 orthogonal planes of the fetal face section, in the left side of the image

number of cases, more than 600, with fetal diagnosis using 3D ultrasonography. In 1993 his team made a diagnosis for facial abnormalities, using a 3D transvaginal scanning. The perception in 3D is done by the combination between deep shadows, a map of colours, the image texture and the combined volume of the rays track. The introduction of **multiplanar** reformatting has enabled the possibility of doing any section arbitrary chosen within the obtained data. In obstetrics this is important for measurements and the reconstruction of critical images (for example the visualization of the four rooms) or the orthogonal scanning of the face and soft palate. All these are dependent on the software' algorithms and the computer's power of processing, the most important of all the devices (1,4).

The volume rendering in medical Imagistics has its roots in the engineering computerized graphics, it has developed as a separate branch of the art, especially in literature computerized graphic before and independent of its application in medicine. One of the first pioneers in this field is Marc Levoy from the University of North Caroline (then at Stanford) (4).

The first English guide of 3D ultrasonography in obstetrics and gynaecology appea-

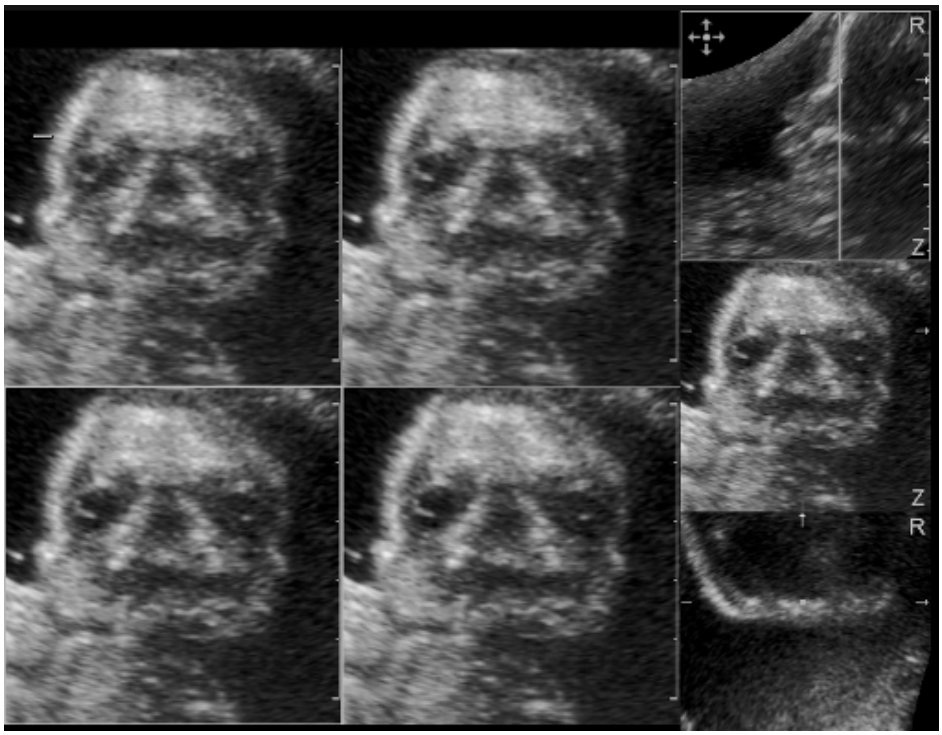

Fig. 3. In the fetus from the previous image, through multiplanar rendering technique, the coronal plane of the face making evident the bone structure of the face. Serial sections at 0,2 mm, having as starting point the base of the nasal bone. The fetal crystalline is seen in both eyeballs

red in 1996, edited by Kazunori Baba and Davor Jurkovic at the Royal University hospital in London. Eberhard Merz hosted the first World Congress of 3D ultrasonography in obstetrics and gynaecology in Mainz, 1997. Many topics of interest about 3D ultrasonography were discused. (1,7).

The important advantage of 3D ultrasonography over the conventional 2D, at the end of the millennium, is the ability to increase the mathernal-fetal relation, it improves the parents understanding of some fetal abnormalities, the recognition and clear confirmation of some abnormalities, for example the cleft lip, polydactyly, micrognatism, malformed ears, crooked legs, malformed spine and other "exterior" visible fetal abnormalities, as a consequence of the benefit brought by the interpretation made by rendering volumes and surfaces (1,9,10).

In an article, Asim Kurjak and his team concluded „Three-dimensional ultrasonography in the prenatal diagnosis: a luxury or a necessity?"

„The main advantage of three-dimensional ultrasonography in perinatal medicine and the prenatal diagnosis includes the scanning in coronal plane, it has improved the assessment of the complex anatomical structures, a surface analyse of the minor deffects, the volumetric measurement of the organs, the visualization of the fetal skeleton in a plastic way, the spatial presentation of the vasculary system and finally the volumes and scanned images storage. It is our definite opinion that the three-dimensional ultrasonography gained a valuable place in prenatal diagnosis, becoming a necessity for the modern centre of perinatal medicine....." (1,4,9,11)

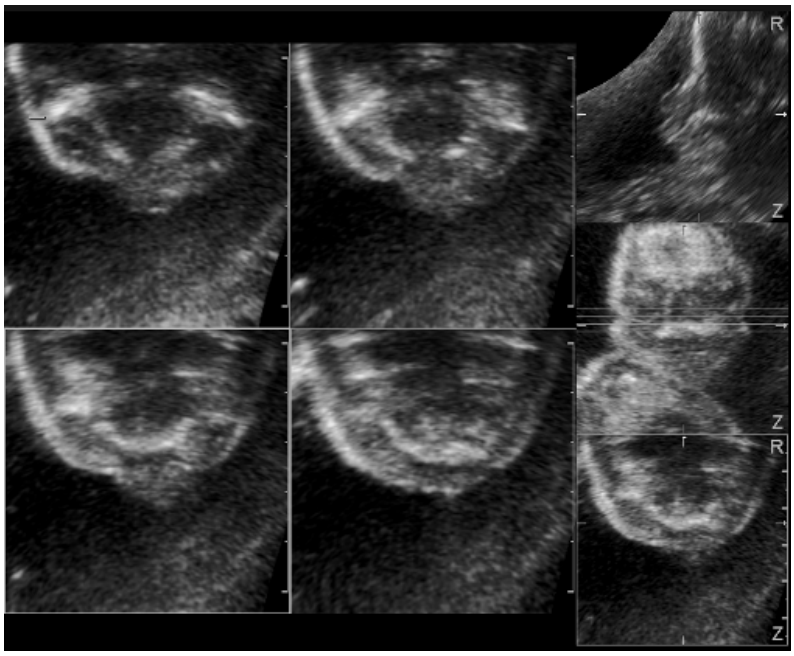

Fig. 4. Transversal sections from1 in 1 mm, through basic coronal plane, chosen in the prevoius diagram, this time with starting point from the palatine bone. It is noticed the rough palate, the orbits base and the malar bone

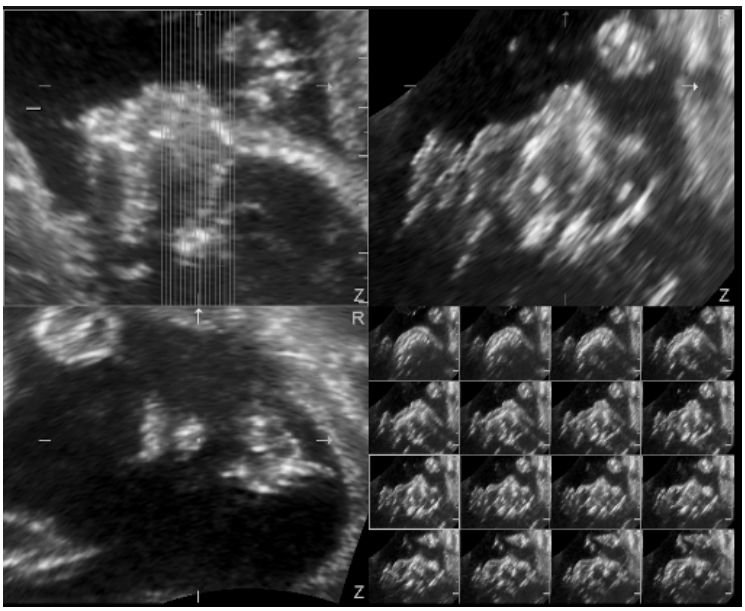

Fig. 5. Transversal sections through sagittal plane of the fetal face, at 1 mm distance. In the upper left part a nasal bone is seen, correspondent in the right corner with both bones in the transversal section. Bottom left to start the green sections, is on the nose, under which - to the left, it highlights the filter and the upper lip

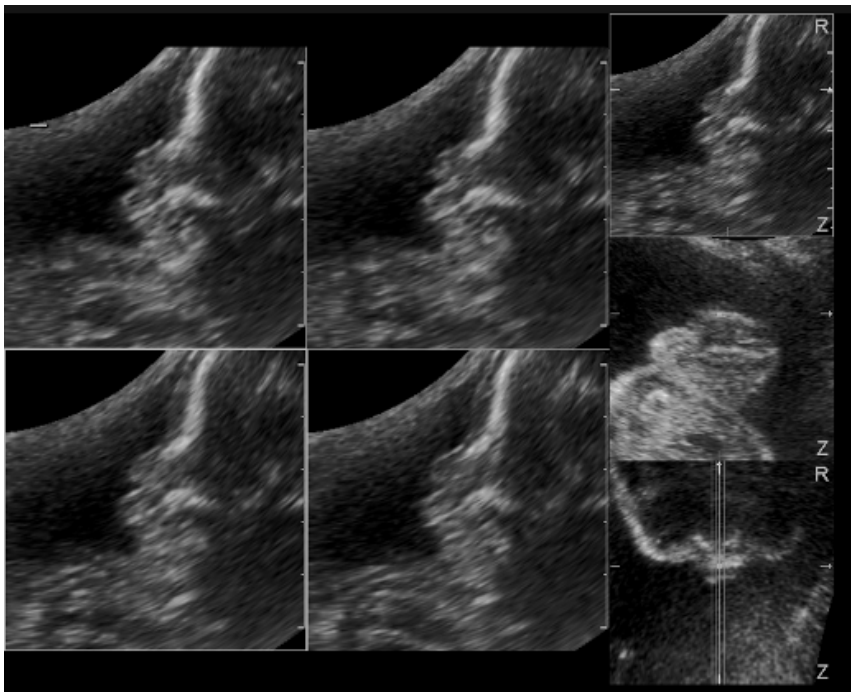

Fig. 6. Parasagitale serial sections, highlighting the nasal bone, the bone palate. On the right, the image from the middle represents the fetal chin, above which are distinguished the lips and the nasal cartilage with nostrils

Another possible benefit of 3D ultrasonography is represented by the possibility of documenting, data storage and communication and also the possibility of new research directions of the developing structures of the human embryo "in utero". Through a digital saving of the data, these can be transfered immediately for another interpretation or a second opinion.

Concerns for 2D ultrasonic study of the fetal face bones, with practical implications dates from the beginning of 2000 - Cicero and his contributors, when it has been noticed the relations between the absence of nasal bone and the trisomy 21 (12). Rotten and the contributors describe the main sections for the definition of normal face through 2D and 3D ultrasonography (13).

The end of 2000 has brought the study of the fetal face through multiplanar three--dimensional ultrasonography, through volume acquisition and its processing. The study of the fetal profile through this method brings new data about maxillary, mandible, naso-maxillo-mandibular angle (14,15). It has also been made a nomogram of the fetal profile sizes, ultrasonographically assessed according to the gestational age (16).

The fetal profile analyzed through 16 parameters measured by a 3D ultrasonography, with the composition of a variable craniofacial index, in *Roelfsema and* his contributors' opinion, it would be useful to estimate the normal and abnormal fetal face (17). Recently, Persico and his contributors have made a nomogram of the length of the nasal bone in fetuses with normal caryotype, at 16-24 gestational weeks, through three-dimensional ultrasonography (18).

The fetal face bones - nasal, maxillary, mandible, the bone palate, those of the orbits, can be studied in dynamic, starting with 12-14

gestational weeks. The best ultrasonographic images can be obtained after 21 gestational weeks, when the fetal size and the connection with the amniotic fluid are good for a volume acquisition, as for the 2D ultrasonography (fig. 1, 2, 3, 4, 5, 6).

INCIDENCE OF ENDOMETRIOSIS-A MATTER OF PUBLIC CONCERN (Abstract): There is an increasing trend in the incidence of endometriomas, the disease affecting about 5-10% of women of reproductive age. **Aim:** To determine the incidence of endometriosis in patients undergoing surgery for gynecological diseases at the "Cuza-Voda" Obstetrics and Gynecology Clinical Hospital from Iasi. **Material and methods:** Retrospective study of 12,178 patients followed up for 5 years (January 2010 to December 2015) assessing the detection rate of endometriosis and possible diagnostic methods, as well as differential diagnosis with other pelvic pathologies. **Results:** Distribution of cases by the six years of study identified an increase in the incidence of endometriosis in our clinic. A possible explication can be the improved diagnostic techniques and, also women's concern with infertility. Of the 12178 operated patients, only 1,100 were diagnosed with endometriosis. The highest incidence was recorded in 2015, 21.10 %. **Conclusions:** The incidence of endometriosis was of 9.03% and showed a rise in the past 6 years, due to the improved diagnostic techniques and women increasing preoccupation with the topic of infertility. **Keywords:** ENDOMETRIOSIS, INFERTILITY, INCIDENCE.

Endometriosis is one of the most frequent diseases in gynecological practice. It affects women of fertile age, being the second cause for surgical interventions after uterine fibromas during premenopause. There is an increasing trend in the incidence of endometriomas, the disease affecting about 5-10% of women of reproductive age (1, 2). It is one of the most important public health concerns, because of the continuous increase in the number of cases. Also, the risk of malignant transformation motivates the numerous researches focused on explaining de development mechanisms and the progression of this disease, 10% of endometrioid carcinomas of the ovary are associated with endometrioid carcinomas of the uterus (3, 4). Symptoms represent another problem, because they can vary from total absence to progressive course with multiple complications (5). Also, it is important to evaluate the implications of the disease regarding infertility. Both endometriosis and the surgical treatment for this disease have fertility consequences, with alterations of the AMH values (6).

The incidence of this disease grew ex-

ponentially, accounting for 2% of the general population, being the third cause for gynecological examination for infertility, chronic pelvic pain, dyspareunia and dysmenorrhea. The prevalence of endometriosis has also an increasing trend, up to 25-50% of infertile women being diagnosed with endometriosis, and about 30-50% of women with endometriosis being infertile. Endometriosis affects 7-15% of women of reproductive age, and 25-30% of all women with infertility, having a high social impact. The incidence of this disease rose exponentially following the introduction of new diagnostic methods such as endovaginal ultrasound and exploratory laparoscopy (7). Endometriosis affects 1% of asymptomatic women and up to 60% of women with chronic pelvic pain (8, 9). Endometriosis has a major social impact, and it was reported that quality of life was significantly reduced in women with endometriosis (9, 10). It is diagnosed in women aged 12-80 years old, with a peak incidence around the age of 28 years old (11, 12).

Studies show that endometriosis has a higher incidence in Caucasian, compared with Afro-Americans or Asian women (13, 14). Also, patients with endometriosis are taller, thinner, and have a significantly lower body mass index (BMI) (14).

The main objectives of this research are to evaluate the incidence of endometriosis in patients undergoing surgery for gynecological diseases at the Iasi "Cuza-Voda" Obstetrics and Gynecology Clinical Hospital, and the impact of endometriosis on quality of life.

MATERIAL AND METHODS

Given that the global estimates of the incidence of endometriosis vary considerably, the aim of our study was to identify the incidence and prevalence of this disease among the gynecological patients admitted to the "Cuza-Voda" Obstetrics and Gynecology Clinical Hospital, Iasi.

This is a retrospective study of 12,178 patients followed up from January 2010 until December 2015 with regard to the detection rate of endometriosis and possible diagnostic methods, as well as differential diagnostics with other pelvic diseases. This study included all patients admitted to the gynecology department. Patients admitted to the obstetrics department were excluded. Surgical interventions were performed either laparoscopically or by open laparotomy. A number of 1,100 of patients met the inclusion criteria, the ones diagnosed with endometriosis either pre or post operatory, histologically confirmed.

Data processing was carried out using *SPSS 18.0.*

RESULTS AND DISCUSSION

In the total of 1,100 surgeries performed during the interval 2010-2015 at the "Cuza-Voda" Obstetrics and Gynecology Clinical Hospital from Iasi the highest incidence was recorded in 2015 - 21.1%. The trend for the following period was upward (fig. 1). The prevalence of surgical interventions in the Gynecological Department ranged from 18.5% in 2010 to 13.8% in 2015, while the trend during the study interval was relatively constant (y = 19.31-0.75x), approximately 14%.

Surgeries for infertility peaked in 2013-19.3% and 2014-19.2%, while the trend for the following period of time was relatively constant (y = 17.41-0.21x), with an estimation for the near future of 16%. During the study interval, the most frequent surgeries involved the ovaries (62.5%), and the peritoneum (31.8%) (fig. 2).

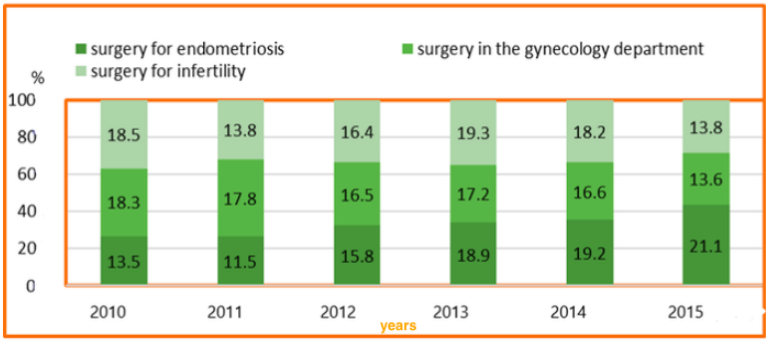

Fig. 1. Distribution of surgeries by study years

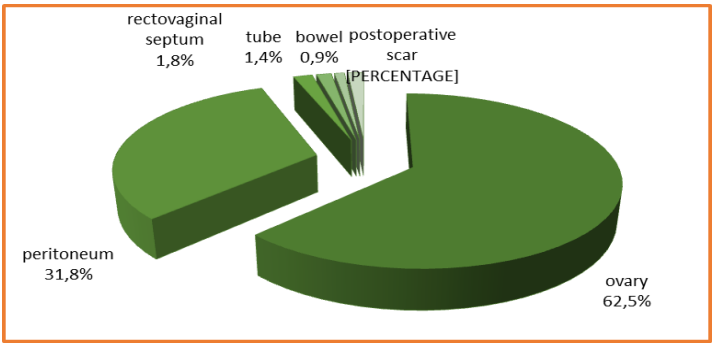

Fig. 2. Frequency of surgical interventions performed between 2010 and 2015 in patients with endometriosis, according to their location

Distribution of cases which underwent ovarian surgery showed a slight increase beginning with 2012 and ranged from 114 cases in 2012 to 139 in 2015.

The number of surgeries for peritoneal endometriosis was relatively constant between 2013 and 2015 (72-75 cases, while the number of surgeries for C-section scar, intestinal, rectovaginal s and fallopian tube endometriosis was low (fig. 3).

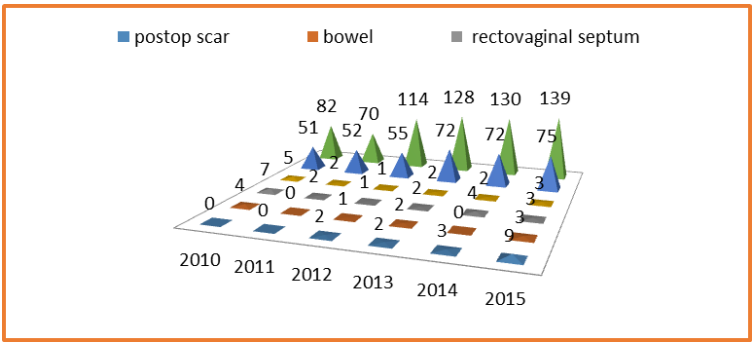

Fig. 3. Distribution of operated endometriosis cases by study years

During the study interval, surgeries for infertility accounted for 10-11% of the total surgical interventions, while surgeries for endometriosis ranged from 9.9% to 14% (fig. 4).

By analyzing the medical records of patients admitted for endometriosis treatment, we found that the main symptom described was chronic pelvic pain, followed by other complaints such as: infertility, dysmenorrhea, dyspareunia, menstrual spotting, ovarian tumor detected during a routine check-up, abnormal menstrual cycles, bowel malfunction and urinary complaints.

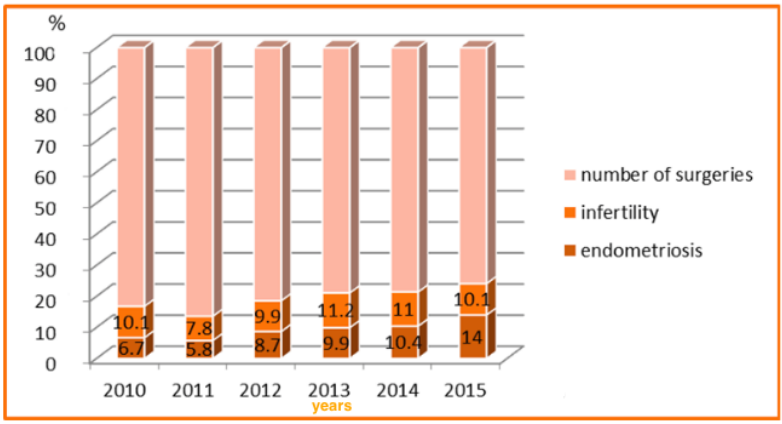

Fig. 4. Prevalence of cases with endometriosis and infertility from the total surgical intervention in the gynecology department

Infertility was described as the impossibility of conceiving after regular, unprotected sexual contacts for 12 months, after excluding any documented cause of male infertility. Also evaluated was the social status of these patients and we noticed that the patients with a higher education level and those with a good socio-economic status had better use of healthcare services, the last ones representing 94.5% of the total number of endometriosis patients. According to civil status, 847 of our patients were in a stable relationship. Of these 72.54% were married, 15.34% were not married, and only 12.12% were cohabitating. As to the place of residence, 953 of the 1,100 patients lived in an urban area and only 147 in rural areas.

Endometriosis is a major public health concern mainly because of the continuously increasing number of cases and the risk of ovarian malignancy. Ten percent of endometrioid carcinomas of the ovary were associated with endometrioid carcinomas of the uterus, fact that motivates the numerous researches focused on explaining de development mechanisms and the progression of this disease (6). The incidence of this disease rose exponentially following the introduction of new diagnostic methods such as intravaginal ultrasound and laparoscopy, an incidence of 2% in the general population being reported. It represents the third cause of gynecological assessment for infertility, chronic pelvic pain, dyspareunia and dysmenorrhea.

The prevalence of endometriosis rose dramatically going up to 25-50% in women with infertility, 30-50% of women with endometriosis suffering also from infertili-

ty. Endometriosis affects 7-15% of women of fertile age, representing 25-30% au sterility cases, with an important social impact (7). The main form of endometriosis that can be found prior to surgical intervention is ovarian endometrioma. Knowing the importance of early diagnosis, pelvic pain, dysmenorrhea, dyspareunia, or infertility can suggest it. Of the total number of patients, 1,100 had an intraoperative diagnosis of pelvic endometriosis, histologically confirmed, accounting for 9.03%. This finding agrees with the data in the literature reporting an incidence of up to 10% (6,15).

Distribution of cases by the six years of study identified an increase in the incidence of endometriosis in our clinic. A possible explication can be the improved diagnostic techniques, and also women's concern with infertility. Ovarian endometriomas are a common manifestation of endometriosis. These "chocolate" cysts are surrounded by a pseudo capsule adherent to the normal ovarian tissue. The ovary can be attached to the peritoneum, bowel and pouch of Douglas, frequently with modified pelvic anatomy.

The incidence of cesarean section delivery grew in the past years so the number of cases with endometriosis at the level of the cesarean scar was also rising. Because endometriosis is frequently underdiagnosed because of the absence of symptoms, its prevalence cannot be precisely estimated. According to studies endometriosis is present in 1% of asymptomatic patients, and in 60% of women with chronic pelvic pain (8, 9).

In 2012, a German study concluded that the incidence of endometriosis is 0.8% (8, 9), and a 2013 study showed that 62% of patients presenting chronic pelvic pain or dysmenorrhea had endometriosis (9, 16). But there are also studies reporting an incidence of endometriosis of 2% in the general population (17) associated with chronic pelvic pain in 70% of cases and with infertility in 25-30% (18, 19). Vercellini *et al.*, in a 2016 study state that 5% of women of reproductive age suffer from this disease (20, 21, 22).

Of the 12,178 operated patients in "Cuza-Voda" Obstetrics and Gynecology Clinical Hospital from Iasi, only 1,100 were diagnosed with endometriosis. From January 2010 till December 2015, there was an increase for the incidence of endometriosis in women in the Moldavian area. Therefore, endometriosis is a disease with constantly increasing incidence, whose etiology is not fully elucidated and, moreover, with a major impact on physical, mental and social health.

From a demographic point of view, the patient with pelvic endometriosis is a woman residing in an urban area, married, with higher education and a high socioeconomic status, presenting to the physician with chronic pelvic pain, dysmenorrhea, dyspareunia and/or infertility. Although all these symptoms have a high sensitivity for endometriosis, their specificity is at the opposite pole, being low. Therefore, both the unique symptoms and the symptomatology should be noted by the clinician in a timely manner, with the exclusion or confirmation as soon as possible of the diagnosis of endometriosis. In our study, we brought up to date the literature data regarding the incidence of endometriosis, and also contributed with the demographic characteristics of our study group.

With the help of the data from literature, we conducted an empirical research of an actual theme, endometriosis being one of the great unknowns of medicine, a fluid

theme that continues to surprise elements of novelty that emerge to the surface, frequently succeeding to induce in error even a close researcher. So, as to endometriosis incidence, we provided not only a much needed up-to-date of known statistical data but also a precise analysis at regional level. The incidence of endometriosis and its impact on women life were studied in a large sample group.

That is why, one of the perspectives opened by this article is the need for a multicenter study, that can sum up data from all regions of Romania in order to obtain a clearer image of these parameters, nationwide, and to compare the Romanian regions and why not, international studies regarding this matter. Also, a multicenter study presents the advantage of identifying new risk factors for the development of endometriosis.

CONCLUSIONS

In our study, the incidence of endometriosis was of 9.03%, with an increase in the past 6 years due to the improved diagnostic techniques and infertility preoccupation among women. Demographically speaking, women with pelvic endometriosis represents the modern person who presents to the hospital with chronic pelvic pain, dysmenorrhea, dyspareunia and infertility. Patients with endometriosis confront themselves with a series of clinical symptoms described above, and also with emotional instability, high stress levels, all of these having a negative impact on the quality of their lives.

NEWS

NEOADJUVANT CHEMOTHERAPY VERSUS UPFRONT DEBULKING SURGERY IN ADVANCED TUBO-OVARIAN CANCER

In a comparison of neoadjuvant chemotherapy and upfront debulking surgery, they noted no difference in overall survival among 1220 women with International Federation of Gynecology and Obstetrics (FIGO) stage III–IV tubo-ovarian cancer. Median overall survival, which was the primary endpoint of the analysis, was 26·9 months (IQR 12·7–50·1) in patients randomly allocated to receive upfront debulking surgery, and 27·6 months (14·1–51·3) in women randomly assigned to neoadjuvant chemotherapy (hazard ratio [HR] 0·97, 95% CI 0·86–1·09; p=0·586). In subgroup analyses, a gain of 3 months in median overall survival was noted for neoadjuvant chemotherapy as compared with upfront debulking surgery in 230 patients with stage IV disease, whereas overall survival was better with upfront debulking surgery than with neoadjuvant chemotherapy in 266 women with stage IIIC disease and extrapelvic metastases smaller than 5 cm (Anna Fagotti, Giovanni Scambia. Neoadjuvant chemotherapy versus upfront debulking surgery in advanced tubo-ovarian cancer.*The Lancet Oncology* DOI: https://doi.org/10.1016/S1470-2045(18)30625-9).

CLINIC AND EPIDEMIOLOGIC ASPECTS OF OVERWEIGHT AND NUTRITIONAL HABITS OF SCHOOLCHILDREN AND TEENAGEERS (Abstract): Obesity is a complex, pluricausal disease that develops through the interaction of social, behavioural, cultural, physiological, metabolic and genetical causes. **Material and methods**: The study was conducted on 1764 school age children from Iaşi city. Data was collected by measuring their weight, height and arterial pressure. 283 children were diagnosed with weight excess and have been questioned about their nutritional habits and life quality. **Results**: It has been concluded that 50.17% of the children were breastfed in the first months of life. The weight excess was frequently correlated with: irregular meal schedule (57.59%), roast meal cooking (69.61%), eating white bread (77.38%), predilection for fat meat (66.78%), processed cheese and butter (69.25%), french fries (68.19%), everyday dessert (62.89%), highly concentrated sweets (cookies, chocolate) (63.95%), biscuits, snacks, chips (73.85%) and sweet juices (66.42%). Inactivity was also an important factor, often associated with weight excess, considering that 60.42% of the children spend their spare time watching TV or playing computer games and only 32.86% of the children practice sport during their spare time. **Conclusions**: Obesity and overweight are pathologies with increasing incidence in our country and they are caused by a combination between genetical factors and, more important, nutritional habits and the amount of time dedicated to physical exercise. **Key words**: OBESITY, ALIMENTARY INVESTIGATION, BODY MASS INDEX, DIAGNOSIS OF OBESITY.

Obezitatea este o boală complexă, multifactorială, care se dezvoltă din interacţiunea dintre factorii genetici şi cei de mediu. Mecanismele ei patogenice sunt încă incomplet cunoscute, dar implică integrarea factorilor sociali, comportamentali, culturali, fiziologici, metabolici şi genetici (1).

Folosind diverse tehnici de măsurare clinicienii pot identifica rapid copiii supraponderali sau obezi. Cu toate acestea diagnosticul este doar primul pas şi cel mai uşor. Cu adevărat dificilă este ajutarea familiior să înţeleagă obezitatea ca o problemă, să conducă măsurile de prevenţie şi să iniţieze tratamentul. Recunoaşterea obezităţii de către părinţi reprezintă un pas esenţial în dieta şi schimbarea stilului de viaţă al acestor copii (2). Atât factorii genetici, cât şi cei de mediu contribuie la etiologia obezităţii.

Obezitatea din cadrul sindroamelor genetice este rară, dar important de recunoscut deoarece poate fi asociată cu complicaţii medicale specifice, cu posibil răspuns la tratament. Multe din aceste sindroame sunt caracterizate prin deficit statural, întârziere în dezvoltare, trăsături dismorfice şi hipo-

gonadism. Ca regulă generală, se poate spune că în situaţiile în care copilul nu prezintă deficit statural pentru vârstă şi sex, nu are întârziere în dezvoltare sau trăsături dismorfice, este puţin probabil ca obezitatea să se datoreze unei tulburări endocrine sau unui sindrom genetic (3).

De-a lungul timpului s-au produs modificări în procentul de principii alimentare din dietă. Se apreciază că în ultimii două sute de ani consumul de proteine a crescut de la 10 la 13%, a scăzut consumul de glucide complexe de la 65 la 45%, iar consumul de lipide a crescut de la 25 la 40% (4). S-a remarcat, de asemenea, că încercarea de contrabalansare a consumului de grăsimi se face prin glucide simple şi nu prin glucide complexe (5). Alţi factori includ scăderea activităţii fizice, inclusiv la copii şi creşterea activităţilor sedentare. Activităţile sociale determină un aport alimentar independent de senzaţia de foame. Supraalimentarea la naştere poate duce la dereglări neuroendocrine care converg la formarea fenotipului obez (6).

MATERIAL ŞI METODĂ

Lotul de lucru a fost alcătuit din copii de vârstă şcolară din oraşul Iaşi, elevi ai şcolilor: „Petru Poni", „George Coşbuc", „Miron Costin", „Ion Simionescu", Grupul Şcolar Economic de Turism şi Şcoala numărul 39. Iniţial, aceşti copii au fost evaluaţi din punct de vedere al greutăţii, taliei şi tensiunii arteriale. Pe baza indicelui de masă corporală, raportat la valorile citate în tabele ca fiind normale pentru vârstă şi sex, grupul supus evaluării primare a fost împărţit în lot control şi lot de studiu (supraponderalitate = între percentila 85 şi 95, şi obezitate = peste percentila 95). Copiii cu exces ponderal (peste percentila 85), au fost chestionaţi ulterior în privinţa particularităţilor nutriţionale (ancheta alimentară) si a calităţii vieţii.

Tensiunea arterială a fost considerată normal înaltă dacă valoarea sistolică sau cea diastolică s-au aflat între percentilele 90 şi 95 pentru vârstă, sex şi înălţime şi am încadrat ca hipertensivi copiii având fie tensiunea sistolică, fie cea diastolică peste percentila 95. Valorile corespunzătoare pentru vârstă, sex şi înălţime au fost cele recomandate de Programul Naţional de Educaţie pentru hipertensiune arterială (7).

REZULTATE

1. Lotul a cuprins **1764** de copii de vârstă şcolară, dintre care 828 (**46,93%**) **băieţi** şi 936 (**53,06%**) **fete**.
2. Analiza IMC în funcţie de sex şi vârstă a permis clasificarea lor în: **obezi** – 54 de copii (**3,06%**), **supraponderali** – 229 copii (**12,98%**), **normoponderali şi subponderali** – 1481 copii (**83,95%**).
3. Determinarea TA la totalul de 1764 copii s-a concluzionat cu **83 de copii** (**4,70%**) având valori crescute ale tensiunii arteriale. Dintre cei 83 de hipertensivi, **14** sunt **obezi**, iar **21** sunt **supraponderali**.
4. Distribuţia copiilor cu exces ponderal după vârstă şi sex este prezentată în tabelul I:
   - Fete: **130 din 936** (**13,88%**), din care 25 obeze (2,67%), 105 (11,21%) supraponderale.
   - Băieţi: **153 din 828** (**18,47%**), din care 29 obezi (3,50%), 124 (14,97%) supraponderali.
5. Am constatat apartenenţa la un nivel socio-economic modest în 72 de cazuri (25,44%), mediu în 194 de cazuri (68,55%) şi superior în 17 cazuri (6%).

În urma anchetei alimentare realizate în cazul celor 283 de copii cu exces ponderal, atât obezi cât şi supraponderali, s-au obţinut următoarele rezultate:

- Din declaraţiile familiilor reiese că au primit o alimentaţie naturală în primele luni de viaţă un număr de 142 de copii (50,17%), mixtă 92 de copii (32,50%) şi artificială 49 de copii (17,31%).

TABELUL I
Repatiţia cazurilor pe grupe de vârstă şi sexe

Vârsta	7-10 ani	11-14 ani	15-18 ani
Obezi (nr.cazuri %)	9 (4%)	22 (3,13%)	23 (2,75%)
Supraponderali (nr.cazuri %)	36 (16%)	111 (15,76%)	82 (9,82%)
Normoponderali (nr.cazuri %)	180 (80%)	571 (81,11%)	720 (87,43%)

- 161 de copii (56,95%) declară un exces de aport alimentar impus, iar voit - 122 de copii (43,04%). În primul caz este vorba de copii la care familia, din diferite motive, insistă în favoarea unui aport alimentar crescut.
- 114 copii (40,28%) au afirmat că au primit în mod repetat suplimente de vitamine şi minerale.
- 86 de cazuri – 30,38% - au declarat că au urmat la un moment dat o dietă, în cele mai multe situaţii fiind vorba despre diete restrictive, care nu au cuprins un program regulat de mese şi de exerciţii fizice, soldate, în general, cu eşec.
- 163 de copii – 57,59% descriu un program neregulat de mese, în timp ce 120 de copii – 42,40% au afirmat că primesc trei mese principale şi două gustări, adecvate vârstei.
- 197 dintre copii – 69,61% - preferă alimentele prăjite, iar 86 dintre copii – 30,38% - pe cele preparate în alte moduri (fiert, la cuptor, grătar) .
- obişnuiesc să consume frecvent carne grasă, mezeluri 189 de copii – 66,78%, brânză topită, unt 196 copii – 69,25%, smântână 97 de copii – 34,27%, iar 148 de copii – 52,29% consumă mai mult de 3 ouă/săptămână.
- În ceea ce priveşte consumul de pâine : 218 copii preferă pâinea albă - 77,38% şi doar 65 primesc pâine neagră sau intermediară - 22,62%. De asemenea, 195 dintre copii consumă < 10 felii/zi - 68,90%, 68 consumă între 10-20 felii/zi – 24,02%, iar 20 de copii mănâncă > 20 felii/zi – 7,06%.
- Declară un consum zilnic de cartofi un număr de 43 de copii – 15,19%, de 4-5 ori/săptămână – 85 de copii – 30%, de 2-3 ori/săptămână – 129 de copii – 45,58%, şi mai rar de 2/săptămână - 26 de copii – 9,18%. Preferă cartofi prăjiţi 193 dintre copii – 68,19%, iar fierţi sau piure 90 dintre copii – 31,80%.
- Consumă lapte – zilnic – 128 de copii – 45,22%, de 4-5 ori/săptămână - 29 de copii – 10,24%, de 2-3 ori/săptămână – 67 de copii – 23,67%, deloc – 59 de copii – 20,84%. Preferă lapte normal 139 de copii – 49,11% şi degresat/parţial degresat 85 de copii – 30,03%.
- Primesc desert zilnic 178 de copii – 62,89%, de 4-5 ori/săptămână – 21 de copii – 7,42%, de 2-3 ori săptămână – 52 de copii – 18,37% şi rareori (< 2/ săptămână) 32 de copii – 11,30%.
- Consumă fructe zilnic un număr de 147 de copii – 51,94%.
- Primesc dulciuri foarte concentrate (prăjituri, ciocolată) 181 de copii – 63,95%.
- Declară un consum foarte frecvent de biscuiţi, snacksuri, chipsuri 209 copii - 73,85%.
- Primesc paste făinoase, pizza – zilnic - 10 copii – 3,53%, de 4-5 ori/săptămână - 19 copii – 6,71%, de 2-3 ori/săptămână - 80 de copii - 28,26% şi rar 174 copii – 61,48%.
- Orez – de 4-5 ori/săptămână - 6 copii – 2,12%, de 2-3 ori/săptămână - 57 copii – 20,14%, rar (< 2/săptămână), 220 copii – 77,73%.

- Consumă zahăr – zilnic 72 dintre copii – 25,44%, rar 102 copii – 36,04%, deloc 109 copii – 38,51%.
- Declară un aport crescut de sare un număr de 254 de copii – 89,75%.
- Apă < 1 l/zi – 131 de copii – 46,28%, 1-2 l/zi – 127 copii – 44,87%, > 2 l/zi – 25 de copii – 8,83%.
- Sucuri dulci – zilnic – 165 de copii – 58,30%, de 4-5 ori/săptămână - 23 de copii – 8,12%, de 2-3 ori/săptămână - 37 de copii – 13,07%, foarte rar – 58 de copii – 20,49%.
- Obişnuiesc să primească zilnic mic dejun un număr de 133 de copii – 47%.
- Cea mai consistentă masă a zilei este reprezentată de micul dejun pentru 11 copii – 3,88%, de prânz pentru 157 de copii – 55,47%, cină la 72 de copii – 25,44%, iar prânz şi cină în proporţii egale pentru 43 de copii – 15,19%.
- Primesc cina după ora 20 – 105 copii – 37,10%.
- Obişnuiesc să mănânce la TV – 150 de copii – 53%.
- Petrec timpul liber la calculator/TV - 171 de copii – 60,42%, iar în aer liber, cu activităţi fizice – 112 copii – 39,57%.
- Efectuează orele de educaţie fizică la şcoală – 184 de copii – 65,01%.
- Practică un sport în timpul liber doar 93 de copii – 32,86%.

DISCUŢII

1. Prevalenţa excesului ponderal în lotul de copii şcolari luat în studiu (16,04% dintre care 3,06% copii obezi şi 12,98% copii supraponderali) este mai mică decât cea descrisă în statisticile din ţările vest europene, dar mai ales din Statele Unite (15-16% doar copiii obezi), dar confirmă că problema excesului ponderal este reală şi în creştere şi la noi în ţară.

2. Repartiţia cazurilor pe grupe de vârstă arată o predilecţie mai mare a acestei patologii pentru vârstele mai mici, iar repartiţia pe sexe indică o uşoară predominenţă a sexului masculin (18,47% faţă de 13,88%), motivată probabil şi de preocuparea mai mare pentru aspectul exterior, pe care o manifestă fetele şi în special adolescentele, comparativ cu băieţii, la această vârstă.

3. Din totalul de 1764 de copii şcolari urmăriţi, 83 (4,70%) au prezentat valori crescute ale tensiunii arteriale. Dintre ei, un număr de 35 de copii au prezentat exces ponderal. Important este faptul că, deşi la vârsta copilăriei hipertensiunea arterială este în principal secundară, în cazurile întâlnite ea are caracteristicile unei hipertensiuni esenţiale, similară celei care apare la vârstă adultă.

4. Majoritatea copiilor luaţi în studiu au avut o alimentaţie naturală în primele luni de viaţă (50,17%). Cu toate acestea, s-a observat că procentul copiilor obezi alimentaţi artificial este aproape dublu faţă de cel al copiilor supraponderali alimentaţi artificial, sugerând că acest tip de nutriţie, iniţiată precoce, ar putea totuşi constitui un factor favorizant în dezvoltatea unui exces ponderal ulterior.

5. Au fost mai frecvent corelate cu excesul ponderal : programul neregulat al meselor (**57,59%** dintre copii), prepararea alimentelor prin prăjire (**69,61%**), consumul de pâine albă (**77,38%**), preferinţa pentru carne grasă, mezeluri (**66,78%**), brânză topită şi unt (**69,25%**), cartofi prăjiţi (**68,19%**), desert zilnic (**62,89%**), dulciuri foarte concentrate (prăjituri, ciocolată) (**63,95%**), biscuiţi, snacksuri, chipsuri (**73,85%**) şi sucuri dulci (**66,42%**).

6. Sedentarismul a fost, de asemenea, un factor mai frecvent asociat cu excesul ponderal, întrucât **60,42%** dintre copii au declarat că petrec timpul liber la calculator/ TV, şi doar **32,86%** practică un sport în timpul liber.

CONCLUZII

Prin urmare, obezitatea şi supraponderalitatea reprezintă o patologie a cărei incidenţă este în creştere şi în ţara noastră, în determinarea căreia se îmbină aspecte ce ţin de factorul genetic, dar mai ales de comportamentul alimentar şi de timpul alocat activităţilor fizice.

În apariţia excesului ponderal familia joacă un rol semnificativ, în primul rând prin adoptarea unui anumit stil de viaţă şi în al doilea rând prin solicitarea/impunerea unui aport alimentar crescut, lucru mai evident la copiii de vârstă mai mică.

NOUTĂŢI

β4-TIMOZINA - UN CANDIDAT PENTRU TRATAMENTUL ACCIDENTELOR CEREBRALE ?

Următoarea frontieră în terapia accidentelor cerebrale ar putea purta numele generic de terapie neurorestaurativă. Exista ipoteza conform căreia imediat după accidentul cerebral apar anumite modificări celulare analoge diferitelor stadii de dezvoltare celulară iniţială. Creşterea expresiei proteinelor de maturare în zona limitrofă zonei infarctate sugerează un răpuns activ de reparare sau recondiţionare a leziunii ischemice. Terapia neurorestaurativă are ca ţintă celulele neuronale, oligodendrocitele, astrocitele dar şi celulele endoteliale, în vederea iniţierii neurogenezei endogene, angiogenezei, creşterei axonale cât şi a sinaptogenezei, cu rezultat final recuperarea funcţională. Tratamentul farmacologic include statine, inhibitori de 5-fosfodiesterază, eritropoetină şi donori de monoxid de azot. Această conduită s-a dovedit a îmbunătăţi manifestarile funcţionale după acidentul cerebral. β4-timozina (Tβ4) este o proteină de sechestrare a actinei, implicată în creştere, motilitate şi metastazare celulară ; acţionează atât în cazul celulei tinere cât şi în cazul celulei adulte. La nivel cerebral, precum şi la nivelul miocardului, determină stimularea proceselor de vasculogeneză, angiogeneză şi arteriogeneză. iniţiind devoltarea neuronală, migrarea şi diferenţierea celulară în aria ischemică (Morris DC, Chopp M, Zhang L, Zhang ZG. Thymosin beta4 : a candidate for treatment of stroke ? *Ann N Y Acad Sci* 2010 ; 1194 : 112-117).

CLINICAL AND ECHOGRAPHIC EVALUATION OF THE EFFECTS OF EPINEPHRINE AND PLATELET-RICH PLASMA SOLUTION ON MODIFIED MCFARLANE SKIN FLAP IN RATS (Abstract): **Aim**: The aim of the study was to test the effects of the administration of the platelet-rich plasma solution in the same time with epinephrine in frequently used skin flap model in rats, and to notice the vascular response of the flap pedicles using ultrasound exploration. **Material and methods**: the experimental study took place at the Advanced Research Centre for Experimental Medicine (C.E.M.E.X), at the "Grigore T. Popa" University for Medicine and Pharmacy Iasi. We used 27 adults male Whistar rats, 6 of them were used as donor source for the PRP (platelet rich plasma) solution. The rest were split in 3 groups of study: on the first group we performed the modified McFarlane 8 x 3 cm, the second group received epinephrine 0.1 mg/kg intraperitoneally, and the third group received 1 mL solution of PRP subcutaneously, in the same points of the flap, alongside epinephrine. In the third postoperative day, a clinical assessment and photographic documentation was done. On the same day, the ultrasound exploration was done. **Results**: we calculated the percentage of skin necrosis, by calculating the areas of normal and necrotic skin, and comparing them. The highest rate of necrosis was observed in the second group (55.3 %) compared with the first group (48.5 %) and the group that received PRP (29.7 %). The second group also had the smallest pedicle's sizes, corelating with the area of skin necrosis. The biggest pedicles were found in the third group. The epinephrine only group had a very important variation of the pedicle's flow speed. **Discussion:** the ultrasonography is a machine and operator-dependent procedure, non-invasive and quick to perform, which brings valuable date regarding small perforators of the skin. In order to analyze such small perforator, like the pedicles of this modified skin flap, it is important to set the correct modes and to choose appropriate anatomical landmarks. Sometimes, it is difficult to measure the dimensions of the pedicles and their flow speed too. Clinical assessment of the flap was assessed in 5th postoperative day. Special digital software is helpful when we want to distinguish other colors apart from white and black, and to strictly delineate the normal skin from the necrotic one. **Conclusions**: our data do corelate with the literature, confirming the effect of the PRP on this type of rat skin flap, even though a small quantity of epinephrine was added. **Keywords**: MCFARLANE SKIN FLAP, PRP, EPINEPHRINE, ULTRASOUND, PERFORATOR PEDICLE.

Severe trauma or tumoral surgical interventions can lead to large soft tissue defects, which result in the exposure of vessels, nerves or osteo-articular structures. The defect has to be repaired taken into consideration the functional and esthetic requirements of the area involved. In time, the development of the vascular physiology of the human and animal skin flaps has led to a great variety of options regarding these reconstructions, no matter if it is a distant free flap or a local perforator free-style flap.

In order to better understand and to avoid the possible complications and failure of the skin flaps, which can lead to local or systemic infections, functional impairment or even amputations, several animal models were used to test a variety of substances that can produce vasodilation, or to study some vascular mechanisms, such as the delay phenomenon or ischemia-reperfusion injuries.

One of the most used animal skin flap models in experimental surgery is the modified McFarlane rat dorsal skin flap. The first description of the flap was in 1965, with a 10 x 4 cm dimension, being cranially based. Since then, there were many changes regarding whether the pedicle should be cranial or caudal, and the dimensions varied between 2 x 7 to 5 x 10 cm (1).

The rat dorsal skin has 3 main arterial sources, the lateral thoracic, the posterior intercostal and the deep circumflex iliac vessels. Usually, the flap is designed to measure 8 x 3 cm, raised at the level of the deep fascia, caudally based, with 2 pedicles coming from the deep iliac vessels.

This design has multiple advantages: it is a pedicled and random skin flap type, the so called rando-axial flap, it has a predictable skin necrosis area and the vascular pedicle is consistent (2, 3).

Using this McFarlane dorsal skin flap as an experimental model, many substances were tested in order to improve the necrosis rate of the random part of the flap, usually the cranial part, and to observe their angiogenic and vasodilatory effects. One of these substances is the Platelet-Rich Plasma solution (PRP), which has been injected in the subcutaneous layer of the flap, predominantly at a certain distance from the pedicles of the flap. The intradermal administration of an inactive PRP solution has led to the decrease of the flap necrosis (4).

Intraperitoneal injection of epinephrine decreased the skin survival of a modified McFarlane flap, which measured 7 x 2 cm, confirming the vasoconstrictive effects of the epinephrine on the cutaneous vessels (5).

Imagistic explorations are frequently used in planning a flap, especially for perforator-based flaps. Ultrasound based technologies are quite simple to practice, non-invasive and are much less expensive than computer tomography or magnetic resonance imaging (MRI). Taken into consideration the fact that the level of dissection when using a perforator flap is not very deep, the color Doppler ultrasonography was successfully used to locate the best and the nearest perforator pedicle adjacent to the defect (6). The use of the color Doppler ultrasound exploration was proved also in planning a free flap reconstruction, when using a free antero-lateral thigh flap for head and neck reconstruction (7).

The aim of the study was to test the effects of the administration of the platelet-rich plasma solution in the same time with epinephrine in frequently used skin flap model in rats, and to notice the vascular response of the flap pedicles using ultrasound exploration.

MATERIAL AND METHODS

The experimental study was performed at the Advanced Research Centre for Experimental Medicine (C.E.M.E.X), at the "Grigore T. Popa" University for Medicine

and Pharmacy Iasi. We used 28 adults male Whistar rats, which were hosted in special cages, with constant temperature and a day/night cycle from 7 a.m. to 7 p.m. The animals received water and food *ad libitum*. Their weight varied between 262-493 g.

The PRP solution was obtained from 6 donor rats, by cardiac puncture. The donor rats were sacrificed. From each rat a volume of 6 to 8 ml of blood was collected. The blood was transferred in special heparinized tubes. The tubes were then centrifugated at a speed of 3,100 rotations/minute, for 10 minutes. After this, the superior layer was separated from the sediment and the content was transferred in small tubes which were again centrifugated for 15 minutes, at a rate of 3,600 rotations/minute. The PRP solution was then transferred in 1 mL recipients.

There animals were divides in 3 groups, 7 animals each. Before any surgical procedure, the animals were shaved and the design of the caudally based dorsal flap (8 x 3 cm) was drawn after the induction of the anesthesia with Isofluran.

During the surgical procedure, the animals were under continuous inhalatory anesthesia, and for the group 1 (named BO1-BO7; animal BO4 died and was replaced by animal BO8*) the flap was raised at the level of the deep fascia, and sutured back to its place after the interposition of a sterile synthetic material, to prevent neovascularization from the subjacent tissue. Under the same sterile and anesthetic conditions, the group 2 (named BO8-BO14) received 0.1 mg/kg epinephrine by intraperitoneal injection, after the dissection and the suture of the flap. The third group (named BO20-BO27, BO22-donor) underwent the same protocol for anesthesia and dissection as the other two, but 1ml of PRP solution was injected subcutaneously at a distance of 5 cm from the pedicles of the flap, before the suture of the flap. After the suture was done, 0.1 mg/Kg of epinephrine was injected intraperitoneally.

The echography was done using a Vevo 2100 Imaging System machine, in the 5th postoperative day. The device is for animal study purposes, and we used the B-Mode for identifying the anatomical landmarks and for putting the transducer in the same place on the flap, the PW mode (pulsed wave) for measuring the direction and speed of the flow, and the color Doppler mode for a better identification of the vessels.

To perform the echography, the animals were under anesthesia with Isofluran and 0.3 U of Ketamine and Xylazine solution were injected (Ketamine and Xylazine solution was a mixture of 0.9 U Ketamine and 0.1 U Xylazine) throughout the procedure when necessary. The animal was placed in prone position. We set the General and Vascular mode for the exploration.

The transducer was placed at the base of the flap, on the cutaneous projection of the pedicles. We started by using the B mode, to observe the local anatomy and to set the landmarks. We switched to the Color mode to see the vascular flow and to identify the pedicles on each side.

To determine the size of the vessels we used the Freeze and Measure function alongside the option Linear, and the transversal diameter of the vessels was determined, above the place where they pierced the fascia and before the bifurcation into the cutaneous branches.

The speed of the flow was determined with the help of the PW function.

After the exploration, the animal was cleaned and taken back to its cage. If necessary, we supplemented the dose of Ketamine and Xylazine, depending on the status of the animal.

RESULTS

In the 5th postoperative day we clinically examined the flaps, and standard pictures were taken, using a professional device. We

calculated the rate of necrosis as a percentage from the total area of the skin flap.

The first group had a mean length of the flap of 7.17 cm and a mean width of 2.92 cm. The percentage of necrosis was 48.5 % from the total area of the flap.

At the second group, the one with injection of epinephrine only, the mean length was 6.98 cm, and the mean width was 2.54 cm. The percentage of necrosis was 55.3 %.

In the third group, the mean length of the flap was 6.67, and the mean width was 2.82 cm. The percentage of skin necrosis was 29.7 %.

The echographic examination found that there were no major differences between the animals from the first group regarding the dimensions of the right and left pedicles (0.45 mm and 0.46 mm). The mean of the flow speed of the two pedicles varied between 178 and 190 mm/s (tab. I).

TABLE I

Ecographic dimensions of the pedicles - First Group

First group	BO1	BO2	BO3	BO5	BO6	BO7	BO8*	MEAN
Right pedicle diameter (mm)	0.26	0.4	0.48	0.45	0.5	0.7	0.38	0.45
Left pedicle diameter (mm)	0.4	0.49	0.38	0.44	0.49	0.56	0.48	0.46
Right pedicle speed of flow (mm/sec)	120	110	220	-	300	200	120	178.33
Left pedicle speed of flow (mm/sec)	120	120	224	-	400	150	130	190.66

For the second group the diameter of the pedicles varied between 0.38-0.48 mm, with a speed of flow between 151-211 mm/s (tab. II).

TABLE II

Ecographic dimensions of the pedicles - Second group

Second group	BO8	BO9	BO10	BO11	BO12	BO13	BO14	MEAN
Right pedicle diameter (mm)	0.45	0.36	0.32	0.46	0.58	0.56	0.65	0.48
Left pedicle diameter (mm)	0.43	0.3	0.25	0.32	0.43	0.34	0.65	0.38
Speed of flow right pedicle (mm/sec)	90	150	-	180	280	280	290	211.66
Speed of flow left pedicle (mm/sec)	100	150	100	110	110	170	320	151.42

The diameters of the pedicles of the third group varied between 0.54-0.55 mm, and the speed of the flow varied between 172-198 mm/s (tab. III).

The dimensions of the pedicles did not vary too much in the first group, as well as their speed of flow. In the second group, the one with epinephrine injected intraperitoneally, the dimensions of the pedicles were smaller. This group had the greatest variation of the speed flow, as well as the highest and the lowest speed of flow.

TABLE III

Ecographic dimensions of the pedicles - Third group

Third group	BO20	BO21	BO23	BO24	BO25	BO26	BO27	MEAN
Right pedicle diameter (mm)	0.78	0.45	0.45	0.67	0.5	0.3	0.63	0.54
Left pedicle diameter (mm)	0.5	0.38	0.92	0.68	0.4	0.4	0.62	0.55
Speed of flow right pedicle (mm/sec)	300	210	180	210	100	190	200	198.57
Speed of flow left pedicle (mm/sec)	110	130	180	290	120	190	190	172.85

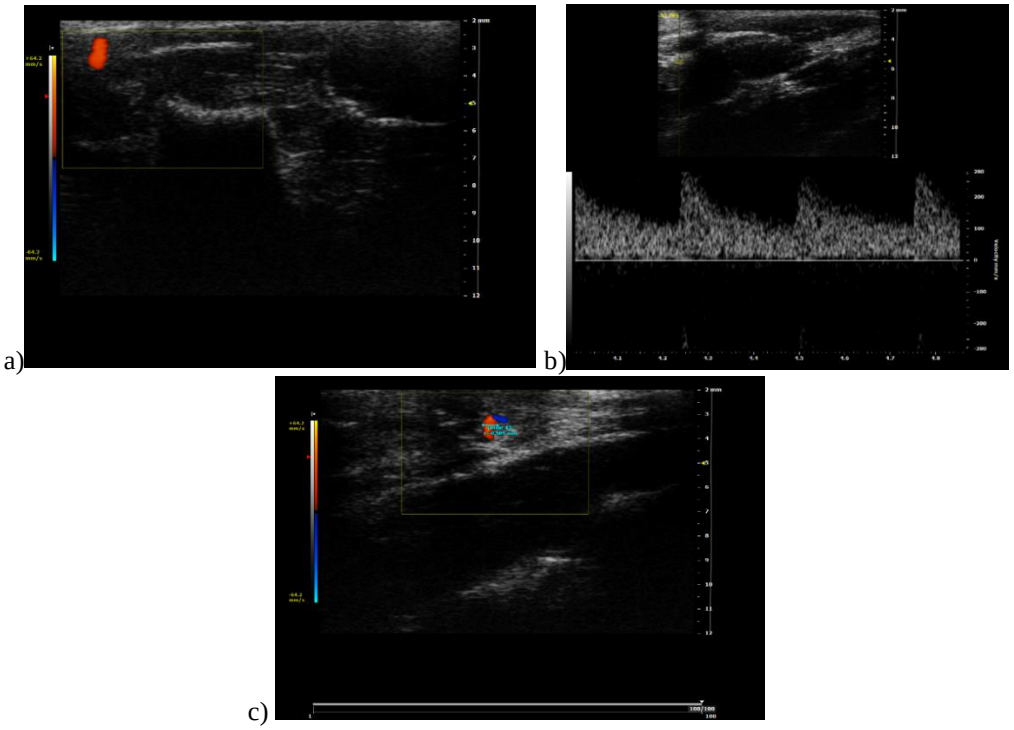

Fig. 1. Identification of the vascular pedicle (a), measuring the flow`s speed (b), measuring the pedicle`s diameter (c)

In the last group, the pedicles had the biggest diameters, a slightly higher variation of the speed flow compared to the first group and smaller compared to the second group.

One animal in the first group (BO4) died during the experiment (cardio-respiratory stop during anesthesia induction) and was replaced by another animal (BO8*).

At one animal (BO5) we did not manage to measure the speed of the flow of the pedicles.

Figure 1 shows the way we found the pedicle, and the measurement of the transversal diameter and the speed of the flow.

Tables IV-VII illustrate the *SPSS* descriptive statistics regarding the three groups with the diameter of the pedicles and the speed of the flows.

TABLE IV

Descriptive *SPSS* - Right pedicles diameters

Group	N	Mean	Std. Deviation	Std. Error	95% Confidence Interval for Mean		Minimum	Maximum
					Lower Bound	Upper Bound		
Group 1	7	0.4514	0.13508	0.05106	0.3265	0.5764	0.26	0.70
Group 2	7	0.4829	0.12010	0.04539	0.3718	0.5939	0.32	0.65

Total	20	170.70	81.340	18.188	132.63	208.77	100	400

We applied the one-way ANOVA method for testing the significance difference between the three means corresponding to group 1, second group and third group. The results are shown in the table VIII and find no statistical difference between pedicle diameters and the speed of the flows in the three groups.

TABLE VIII

ANOVA Test - Group 1-3

Parameters	p - significance
Right pedicles diameters	0.501
Left pedicles diameters	0.110
Right pedicle speed of flow	0.729
Left pedicle speed of flow	0.707

DISSCUSION

Doppler echography strictly depends on the quality and the settings of the device on which is performed. It is preferable to have only one person to do it. The choice of anatomical landmarks is crucial, as well as following the same sequence of choosing the modes. It is cheaper and takes a much shorter time than MRI exploration for example, but it may not give many information regarding the status of the microcirculation and the areas of perfusion. Even so, the Doppler exploration was used to identify capillary perforators smaller than 0.5 mm on the anterior border of the latissimus border

muscle, when planning a thoracodorsal artery perforator flap in humans.

Their identification guided the dissection which was safe and uneventful (8).

The pedicles of this model of rat dorsal skin flap are quite small, and sometimes very difficult to identify, and to measure their speed of flow. The movements of the transducer were very limited, as not to lose the vessel or to compress it with the transducer. Good anesthesia is of huge importance for this kind of exploration.

When analyzing a skin perforator, we have to determine the size of it and the perfusion pressure. These values are of importance when designing a perforator-based skin flap, which nowadays are more and more frequently used because of the minimal sacrifice of tissue and limited dissection. Recent studies confirmed a direct link between the internal diameter of a cutaneous perforator and its perfusion pressure. The perfusion pressure of a certain cutaneous perforator is decisive in establishing its skin territory that can be safely included in the flap (9).

In free flap models in rats, the perfusion pressure was better monitored by transit time ultrasound technologies, and for the venous congestion laser-Doppler flowmetry was used (10, 11).

The clinical aspect of the flaps does corelate with the dimensions of the pedicles. The smallest pedicles were found in the second group, the one with the highest necrosis rate.

There was a huge variation of the speed of the flow in the group were only epinephrine was administrated, with the lowest and the highest speed encountered, which illustrates the important rheologic impact that epinephrine may have, determining vasoconstriction and a possible compensatory vascular response. The speed of flow between the group with PRP and the first group were quite similar.

The fact that we found the biggest diameters of the pedicles in the group where PRP was administrated, confirms the vasodilatory effects of the platelet derived growth factors. They corelate with a smaller area of skin necrosis, and maybe with a bigger number of small skin anastomotic vessels to be opened. Even though the injections were done at a distance of 5 cm caudal to the pedicles, still there was a vascular response from them.

The injections with PRP were first recorded in sport related injuries, and nowadays it has a broad spectrum of indications: from articular degenerative disease to facial rejuvenation, or alopecia. When activated, platelets produce a variety of growth factors such as vascular endothelial growth factor, platelet derived growth factor, fibroblast growth factor, epidermal growth factor or interleukin 8. Its anti-inflammatory effects and the stimulation of different types of cell proliferation, along with being an autologous product, made its use safe and efficient (12).

It has been injected as well on the modified McFarlane dorsal skin flap. Apart from obviously improving the survival rate of the flap, it had proven proangiogenic stimulating effects (13).

There is a continuous search of vasodilator and proangiogenic substances, especially those who are safe to administrate and do not have impact on other organs or functions, that are autologous, such as the human placental extract, which seems to improve the survival rate of a random portion of the dorsal skin flap in rats, due to its antioxidant and antiapoptotic effects (14).

The form of administration is still debated, and can vary from various gels topically applied to subcutaneous injections or to subdermal gas administration, such as the nitrous oxide, that was found to improve the microcirculation of the dorsal skin flap in

rats (15).

CONCLUSIONS

Our study confirms the effects of epinephrine on the modified McFarlane rat dorsal skin flap. When injecting PRP in the flaps of the rats that received epinephrine intraperitoneally, the survival rate of the flap increases, proving the vasodilatory effects of the PRP. Clinical evaluation of these flaps should not be done before 3 days postoperatively and should have standard professional photographic assessment. It is preferable to have a dedicated soft for interpreting the images obtained, in order to better differentiate the colors that may appear on the surface of the flap.

Ultrasound examination gives very important information such as the diameter of the vessels, as well as the flow in each pedicle of this dorsal skin flap. In order to get this data, it is advisable to have one member of the working team to perform it and to set its position along with the anatomical landmarks. Using the correct sequence of exploration, like starting in mode B and switching to Collor function after identifying the pedicles ensures an optimal result.

There are some imagistic explorations that may be performed in order to analyze the skin perforators or microcirculation, such as MRI, thermography or contrast enhanced ultrasound, each one depending on the financial resources and the training of the personnel involved.

To sum, the ultrasound exploration provides valuable data even for this very small cutaneous perforator, but good anesthesia, skills and patience being mandatory for successful recording.

The PRP solution is an autologous product, already tested in chronic wounds and skin flaps, reminding about the intense studies in various fields of medicine regarding the use of the stem cells. Its effects on the endothelial layer and its actions in ischemic conditions are still a subject to be researched.

NEWS

LUTEOLIN, A FLAVONOID AS AN ANTICANCER AGENT

Diet and consumption of bioactive compounds from natural sources (fruits and vegetables)have been recognized for their preventive role against a variety of human diseases including cancer. The inhibitory effects of phytochemicals found in plants against major diseases are well documented in literature. In this context, luteolin, a flavonoid found in different fruits and vegetables has been known as an anticancer agent through inducing apoptosis and cell cycle arrest and trough inhibiting metastasis and angiogenesis in multiple cancer cell lines such as breast, colon, pancreatic among other. Luteolin can be an important complementary medicine for the prevention and treatment of different types of cancers, owing to its natural origin safety and low-cost relative to synthetic cancer drugs. However, since most of the findings are based on in vitro and vivo studies, which do not necessarily represent the effect on humans, more work on different pharmacokinetic parameters and may involve human subjects is needed in the future before this substance becomes a prescribed drug. Luteolin (3,4,5,7 tetrahydroxy flavone) is an natural flavonoid, extensively present in many plant species. It is particularly present in fruits and vegetables such as celery, chrysanthemum flowers, sweet bell pepper, carrots, onion leaves, broccoli and parsley (Muhammad Imran, Abdur Rauf, Tareq Abu-Izneid, Muhammad Nadeem, Mohammad Ali Shariati, Imtiaz Ali Khan, Ali Imran, Ilkay Erdogan Orhan, Muhammad Rizwan, Muhammad Atif, Tanweer Aslam Gondal, Mohammad S. Mubarak, *Biomedicine & Pharmacotherapy*, April 2019, Volume 112).

PRO-HYPERTENSIVE ENDOTHELIAL DYSFUNCTION DUE TO LOWER EXTRACELLULAR MAGNESIUM INVOLVES IK1 CHANNELS

PRO-HYPERTENSIVE ENDOTHELIAL DYSFUNCTION DUE TO LOWER EXTRACELLULAR MAGNESIUM INVOLVES IK1 CHANNELS (Abstract): Endothelium-dependent relaxation (EDR) in resistance arteries is largely independent of nitric oxide (NO) synthase and cyclooxygenase. It is mediated by endothelium-dependent hyperpolarization (EDH), based on endothelial Ca^{2+}-activated K^+ channels: IK1 with intermediate conductance (iK) and SK3 with small conductance (sK). Mg^{2+} modulates vascular reactivity directly and via NO-mediated EDR. **Aim:** We examined effects of diminished extracellular Mg^{2+} (Mg_e) concentration upon EDH-mediated EDR. **Material and methods:** Using wire myography, we tested isolated small mesenteric arteries from male rat. EDH-mediated EDR was induced by acetylcholine 10^{-8}-10^{-4} M, in vascular rings contracted by phenylephrine 10^{-5} M, in presence of l-NAME 10^{-4} M and indomethacin 10^{-5} M, with [Mg_e] kept at 1.2 mM (regular) or 0.8 mM (lower). **Results:** EDH-mediated EDR was inhibited by lower [Mg_e] (n=6; $p<0.001$; multiple *t-test*). Maximal EDH-mediated EDR was reduced from 75.79±2.6 % in regular [Mg_e] to 64.64±2.53 % in lower [Mg_e]. iK blocker TRAM-34 inhibited EDH-mediated EDR similarly in regular and lower [Mg_e], but sK blocker UCL 1684 inhibited EDH-mediated EDR more in lower [Mg_e] than in regular [Mg_e] (n=6; $p<0.001$; multiple *t-test*). Thus, lower [Mg_e] inhibits EDH-mediated EDR further when sK are blocked, but not when iK are blocked. **Conclusions:** Lower [Mg_e] inhibits EDH-mediated EDR, due to negative interference with iK. This novel pro-hypertensive mechanism is relevant for endothelial dysfunction in arterial hypertension associated with hypomagnesemia and for Mg therapy in general.
Keywords: MAGNESIUM, ENDOTHELIUM-DEPENDENT RELAXATION, RESISTANCE ARTERIES, EDH, CALCIUM-ACTIVATED POTASSIUM CHANNELS.

Systemic small arteries and arterioles ensure controlled blood flow distribution plus their dominant and regulated contribution to peripheral resistance. The latter determines arterial blood pressure (ABP) by hemodynamic laws. Vascular reactivity, including endothelium-dependent relaxation (EDR) of vascular smooth muscle (VSM), is key factor for local blood flow and ABP. Endothelial dysfunction has multiple facets and definitions. Here the term denominates all endothelial malfunction favoring vasoconstriction *vs* vasodilation.

Various studies examined Mg implica-

tions in the wide context marked above (1, 2). It has long been known that extracellular Mg^{2+} (Mg_e) induces vasodilation when [Mg_e] raises enough above normal. Mg_e-induced vasodilation involves direct VSM relaxation and EDR mediated by nitric oxide (NO) (3). In turn, NO-mediated EDR requires Mg_e (4).

EDR in resistance arteries is mostly independent of NO-synthase (NOS) and cyclooxygenase (COX), being mediated by endothelium-dependent hyperpolarization (EDH) (5). More precisely, EDH-mediated EDR depends on endothelial Ca^{2+}-activated K^+ channels (K_{Ca}) of two types (6, 7, 8, 9): (a) charybdotoxin-sensitive of intermediate conductance (iK) (alternative names: iK_{Ca}, SK4, $K_{Ca}3.1$, IK1, KCNN4); (b) apamin-sensitive of small conductance (sK) (alternative names: sK_{Ca}, SK3, $K_{Ca}2.3$; gene KCNN3). EDH-mediated EDR is an important functional opponent of sympathetic vasoconstriction (10) and it is clearly involved in flow autoregulation, myogenic response, and vasomotion (11). EDH-mediated EDR is compensatory in the endothelial dysfunction resulted from lower NO availability/effectiveness but is also involved in pathogenesis of endothelial dysfunction and hypertension (8, 9, 12, 13, 14).

Mg_e effects upon EDH-mediated EDR, or upon iK and sK, have not been previously investigated. Only one study seems available, but that is weakly related, because effects of Mg_e itself on EDH-mediated EDR were not examined (15). They found only that high $[Mg]_e$ attenuates the inhibition upon EDH-mediated EDR when such inhibition is exerted by the high [K^+] in cardioplegic solutions (15). Two other studies may come near, but Mg effects on EDH-mediated EDR were not tested therein either (16, 17). They studied the effect of chronic Mg upon l-NAME-induced hypertension and also tested EDR of isolated resistance arteries (16, 17), but in one study the effect of $[Mg]_e$ in the medium was not examined (16), while in the other study only the effect of $[Mg]_e$=4.8 mM (i.e. higher than normal) was tested (17). We started this study due to: (a) lack of previous investigations of Mg_e influence upon EDH-mediated EDR or upon the involved iK and sK; (b) vivid research on EDH-mediated EDR (5, 8, 9, 10, 11, 12, 13, 14, 18); (c) our group's interest in vascular research and hypertension (18).

MATERIAL AND METHODS

Male adult Wistar rats (~200 g) were euthanized. Jejunal loops were removed and placed in physiological saline solution (PSS), containing (mM): NaCl 119; KCl 4,7; $CaCl_2$ 2,5; $MgSO_4$ 1,2; $NaHCO_3$ 25; KH_2PO_4 1,18; glucose 5,5. In PSS at ~5°C, 1 mm rings from first order branches of superior mesenteric artery were dissected and mounted in wire myographs. Rings were then oxygenated (95% O_2 + 5% CO_2) and kept at 37°C (pH 7.2-7.4). After 30' equilibration under 1 g passive tension, rings were checked twice for complete EDR by 10^{-5} M acetylcholine upon contraction by 10^{-5} M phenylephrine. After drug washout for 15', the medium was either kept with regular [Mg_e] or switched to lower [Mg_e] and a 15' re-equilibration period was allowed for all rings. Lower [Mg_e] modified PSS contained 0.8 mM [$MgSO_4$] and was obtained by the required isoosmotic replacement of $MgSO_4$ with NaCl.

In presence of 10^{-4} M N(γ)-nitro-L-arginine methyl ester (l-NAME) and 10^{-5} M indomethacin, rings were contracted by phenylephrine 10^{-5} M and EDH-mediated EDR was induced by cumulative acetylcho-

line, 10^{-8} M to 10^{-4} M (5' of stable plateau before next dose). This was tested as control (without other drugs) or under selective full block (8, 19, 20) either of iK by TRAM-34 (TRAM; 10^{-5} M) or of sK by UCL 1684 (UCL; 10^{-7} M). Each ring was randomly subjected to only one of the six protocols described; one of the three tests above, performed either in regular or lower [Mg_e]. Inhibition of active tension at each acetylcholine concentration was expressed as % of complete relaxation from contraction by PHE 10^{-5} M. In the end each ring was subjected to 30' drug washout in regular [Mg_e], and again to relaxation by 10^{-5} M acetylcholine upon contraction by 10^{-5} M phenylephrine. All drugs were from *Sigma*. Statistics (using *GraphPad*): data expressed as mean ± SD; n=6 in each group; two-way *ANOVA*, multiple *t-test*, extra sum-of-squares F test for EC_{50} comparison; $p<0.05$ significance limit in all procedures.

This study was approved by Research Ethics Commission of the host institution. All procedures comply with guidelines from: Act on Animal Experimentation and Animal Health and Welfare from Romania; Universities Federation for Animal Welfare; Directive 2010/63/EU of the European Parliament and of the Council of 22nd of September 2010.

RESULTS

We observed that EDH-mediated EDR tends to decrease in lower [Mg_e], which could be explained by Mg^{2+} actions involving iK/sK, major players in EDH-mediated EDR. Our initial observation lead to an entirely novel hypothesis: a relatively small [Mg_e] lowering could induce endothelial dysfunction. The initial observation and subsequent hypothesis were confirmed (fig. 1, 2), but after some key preliminary tests, as described below.

First, we choosed the tested [Mg_e] to be 0.8 mM, a moderately diminished [Mg_e], that we expected to reduce EDH-mediated EDR without inducing VSM tone changes by itself. In rings at rest, in presence of l-NAME 10^{-4} M and indomethacin 10^{-5} M, isometric tension was similar upon simple [Mg_e] switch from 1.2 mM to 0.8 mM (n=6; $p>0.05$; paired *t-test*). This proved also valid for rings precontracted by phenylephrine 10^{-5} M (n=6; $p>0.05$; paired *t-test*). These preliminary tests show that [Mg_e] effects on EDH-mediated EDR are not biased by [Mg_e] effects on resting/activated vascular tone. We used TRAM (10^{-5} M) and UCL (10^{-7} M), concentrations that efficiently and selectively block iK and sK respectively, in terms of EDH-mediated EDR in small mesenteric arteries of the rat (19, 20). We separately confirmed (n=6) in the current setup the well-known abolition of EDH-mediated EDR by the combination iK-blocker + sK-blocker.

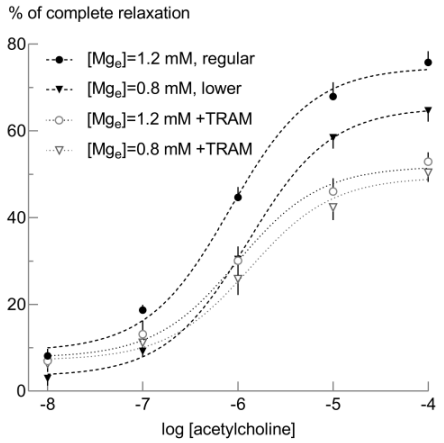

Fig. 1. EDH-mediated EDR is inhibited: (a) in lower [Mg_e], 0.8 mM *vs.* regular 1.2 mM; (b) by TRAM-34 (TRAM, 10^{-5} M), similarly in [Mg_e] 0.8 *vs.* 1.2 mM

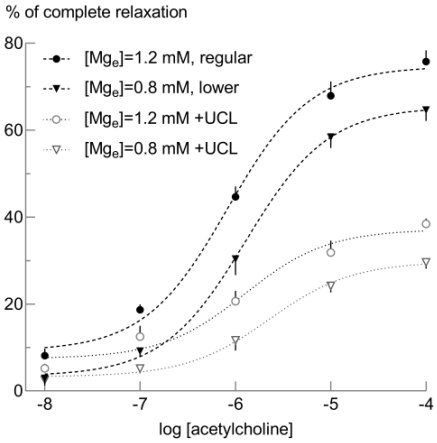

Fig. 2. EDH-mediated EDR is inhibited: (a) in lower [Mg_e], 0.8 mM *vs.* regular 1.2 mM; (b) by UCL 1684 (UCL, 10^{-7} M), more in lower [Mg_e] (0.8 *vs.* 1.2 mM).

DISCUSSION

In the context of massive research on EDR (5) and that of sustained interest in Mg relevance for vascular pathology (1, 2, 21), some studies tested the interplay between Mg and EDR of isolated arteries (3, 4, 15, 16, 17). Here we show that [Mg_e] influences EDH-mediated EDR, the major EDR pathway in resistance arteries. As detailed in the introduction, [Mg_e] effects on EDH-mediated EDR have not been tested before, not even in the three studies somewhat closer to the issue (15, 16, 17).

EDH-mediated EDR can be reduced through a yet unidentified path that allows lower [Mg_e] to hinder iK (but not sK) contribution within (figs. 1, 2). Whatever the mechanistic details, undiminished [Mg_e] could be required for normal function of the iK-based step in EDH-mediated EDR. This step is common, essential and rather late, somewhat beyond the preceding variable elements involved (5, 10, 11, 13, 14, 18). [Mg_e] effects (fig. 1, 2) could involve changed intracellular [Mg^{2+}] ([Mg_i]). As Mg_e effects on iK/sK and Mg_i effects on EDH-mediated EDR seem previously uninvestigated, we just note the only two studies on the effect of Mg_i on iK; patch-clamp showed that Mg_i inhibits iK (22, 23). There is no evidence of iK stimulation by Mg^{2+} and our results cannot be explained by Mg^{2+} inhibition of iK (either directly or indirectly by reducing Ca^{2+} influx), because such actions would lead to effects opposite to our data (figs. 1, 2). This includes iK in endothelial projections, which act in feedback with Ca_L in VSM (11, 24).

Mg_e inhibits L-type Ca^{2+} channels (Ca_L) in VSM (25, 26), the main Ca^{2+} influx path for VSM contraction. Mg_e stimulates K_{Ca} with large conductance (BK) in VSM (27). So, Mg_e promotes VSM hyperpolarization and relaxation, by Ca_L inhibition and BK stimulation. These Mg_e actions in VSM explain how EDH-mediated EDR is reduced in lower [Mg_e] (figs. 1, 2). The effect relies on iK (fig. 1) but not sK (fig. 2), so maybe the particular mechanism involving iK in endothelial projections (11, 24) is somehow affected by lower [Mg_e].

Endothelium-dependent contracting factors (EDCF) (5) may be involved in [Mg_e] effects (figs. 1, 2), except COX-dependent EDCF; COX was blocked by indomethacin. Given the exposure duration, the effects (figs. 1, 2) seem due to acute changes in cell signaling, not involving changes in gene expression, so we did not verify the opposite. However, all effects were rapidly and completely reversible, as shown in the end of each experiment: 30' washout in regular [Mg_e] and complete EDR by 10^{-5} M acetylcholine upon contraction by 10^{-5} M phenylephrine. Despite their high statistical significance, the differences that we revealed may look small (figs. 1, 2). However,

in vivo small changes in VSM active tension turn into small changes in diameter, which turn into corresponding 4th power changes in resistance to flow (Hagen-Poiseuille).

So, lower [Mg_e] reduces EDH-mediated EDR by negatively interfering with iK. This novel path is relevant in the hypertension with Mg deficit and also as reason for Mg supplementation (1, 2, 21). [Mg_e] relation with EDH-dependent EDR adds to known Mg benefits: direct and NO-mediated VSM relaxation, antioxidant, anti-inflammatory. Advances hereafter may impact the future of Mg therapy.

CONCLUSIONS

Low [Mg_e] inhibits EDH-mediated EDR, which is the major EDR mechanism in resistance arteries and relies on iK and sK. Low [Mg_e] further inhibits EDH-mediated EDR when sK are blocked, but not when iK are blocked. Regular EDH-mediated EDR presumably requires [Mg_e] not to be decreased. Otherwise, iK (but apparently not sK) would be hindered in their usual activation and/or involvement therein. Hypomagnesemia may well reduce EDH-mediated EDR in vivo, due to this ability of lower [Mg_e] to negatively interfere with iK. Most recent research shows that such a mechanism is relevant to endothelial dysfunction in hypertension. [Mg_e] effects on EDH-dependent EDR might become important in Mg pharmacotherapy.

ACKNOWLEDGEMENTS

As member of that research team, Dragomir N. Şerban received support from a Romanian National Research Grant lead by Radu Iliescu (code PN-III-P4-ID-PCE-2016-0126). GHEORGHE MARINESCU (1863-1938) AND *LA CELLULE NERVEUSE*. 110 YEARS SINCE WRITTING OF THE MAJOR CHAPTER OF THE OLD TESTAMENT OF NEUROPATHOLOGY (Abstract): 110 years ago, in 1909 in Paris, Gheorghe Marinescu's *La Cellule Nerveuse* appeared. The work was practically a complete and extremely rich review of the literature of that time, in which Marinescu integrated the results of his own research. The book contained chapters on embryology, cytology and physiology of the nerve cell, but also on the pathology. *La Cellule Nerveuse* also recalls Marinescu's pioneering studies in the field of neuronophagy, as well as his studies in the field of chromatolysis. Nowadays, *La Cellule Nerveuse* and the whole activity of Gheorghe Marinescu in the field of neuropathology have been an important pillar not only for the development of the Romanian School of Neurology and Neuropathology, but also for the development of the European neurology that we should remember today. **Keywords:** GHEORGHE MARINESCU, NEUROPATHOLOGY, ROMANIAN SCHOOL OF NEUROLOGY AND NEURO-PATHOLOGY, NERVOUS CELLS.

HISTORICAL DATA

The founder of the Romanian School of Neurology and Neuropathology, Professor Gheorghe Marinescu (1863-1938) (fig. 1), was born on 23rd of February 1863 in Bucharest. In 1874 he was enrolled by his mother at the Central Orthodox Seminary, which he completed the second of his promotion. Refusing the mother's desire to continue his theological studies, young George is admitted to both the Faculty of Medicine and the School of Bridges and Roads.

After the first year, he will remain only at the medical school, where he will work as a student in the newly founded histology laboratories by Professor Petrini-Galatz, the first head of the Department of Histology of the Faculty of Medicine in Bucharest. Later, in 1886 he became assistant in this laboratory and intern of the Brancovenesc

Hospital from Bucharest (fig. 1) (1).

He was Professor Victor Babes' assistant, within the Institute of Bacteriology (2). He became his disciple and they collaborated together on the *Atlas of Pathological Histology of the Nervous System* (3). In 1889, the young George was elected president of the League of Medical Students and by a letter of recommendation signed by several teachers including Victor Babes, he was admitted to a scholarship for a period of nine years at the Salpêtrière Hospital in Paris (fig. 2), where he will study neurology (2).

Fig. 2. Jean Martin Charcot (1825-1893) (a). A Clinical lesson at the Salpêtrière (with Prof. Charcot and others) (1887), André Brouillet (1857-1914), Paris Descartes University, Paris (b) Marinescu is missing from the painting, because he arrived at the Salpêtrière in 1889, two years later (public domain).

At that time, the famous hospital was led by Jean-Martin Charcot (1825-1893) (fig 2), the founder of modern neurology. About Charcot, later in 1925 Marinescu noted: *I had the opportunity to meet personally not only the most renowned neurologists contemporaries, but also great scientists, such as R. Virchow, R. Koch, P. Ehrlich. Neither one made an impression as profound as Charcot, an impression that remains alive in my soul* (4).

Marinescu remained a volunteer assistant at Salpêtrière and collaborated with Pierre Marie (1853-1940), Gilles de la Tourette (1857-1904), Paul Oscar Blocq (1860-1896) and Joseph Babinski (1857-1932) (5). He also traveled to different universities in Europe, where he met and studied with Carl Weigert (1854-1904) in Frankfurt and Emil du Bois-Reymond (1818-1896) in Berlin (1, 3, 5, 6).

After defending his doctoral thesis in Paris, *The Succulent Hand in Syringomyelia,* Marinescu returns to Bucharest where he was appointed as Chief doctor at Pantelimon Hospital in May 1897 (6). For a period of more than 20 years he traveled daily around 12 km to the hospital, until the Neurological Clinic was transferred to the Colentina Hospital (4).

At Pantelimon Hospital, together with his first intern, Constantin I. Parhon (1874-1969), he reorganized the service starting with new laboratory researches in the field of neuropathology. One month later, in July 1897, at the age of 34, Marinescu becomes the first Head of the Department of Neurology of the Medical Faculty of Bucharest (6).

Marinescu's main area of interest was neuronal pathology, and his observations and hypotheses were published in 1909 in Paris, in his monograph *La Cellule Nerveuse (The Nervous Cell)* (3), in which he postulated that: *evolution and involution of neurons depend on active oxidation* (5). In this book he wrote about the cell biology of the neuron and its organelles, such as neurofibrils, pigments, Nissl bodies, the nucleus and nucleoli, both in the normal and the pathological status of the nerve cell. Although his work in this field of neuropathology has been extensively described and published in this book, he did not stop to work and continued until his death in 1938 (2).

THE MAIN NEUROPATOLOGICAL WORK: THE NERVOUS CELL

La Cellule Nerveuse (fig. 3) was practically a complete and extremely rich review of the literature of that time, in which Marinescu integrated the results of his own research (2), being the first book of its kind in the world, greeted with enthusiasm by scientists like Santiago Ramón y Cajal (1852-1934) and it has not been surpassed until today by any such work. This was due to the fact that Marinescu did not study the fixed and colored nerve cell only under the microscope, but also investigated it in the living state (4).

In volume I, Marinescu presents the general morphology of the neuron with all its components known at that time using optical microscopy and fixation and staining techniques (7). He reviewed in detail: nucleus and nucleoli, Nissl bodies, centrosome, neurofibrils, Golgi apparatus, bioblasts of Altmann (e.g. mitochondria) and the colored granules (black pigment for *locus niger* and *locus coeruleus*, as well as yellow pigment) (2, 7).

Regarding neurofibrils, Marinescu considered that they are inserted at the periphery of the cell and at the wall of the nucleus,

naming this structure *spongioplasma*. He was also the first to conclude that spongioplasma lesions can lead to degeneration of peripheral extensions of the nerve cell (8).

Regarding the role of the chromatophilic elements, Marinescu considers that they conducts the nervous impulses and furthermore, the large chromatophilic elements influence the intensity of the nerve impulse. He was also convinced that: *chromatophilic elements represent a substance with high chemical potentials, which is the place of a continuous phenomenon of integration and disintegration, and through these phenomena the nerve cell becomes an energetic device* (translation of the authors) (1). He also named these structures, generically, under the term *kinetoplasma* (9).

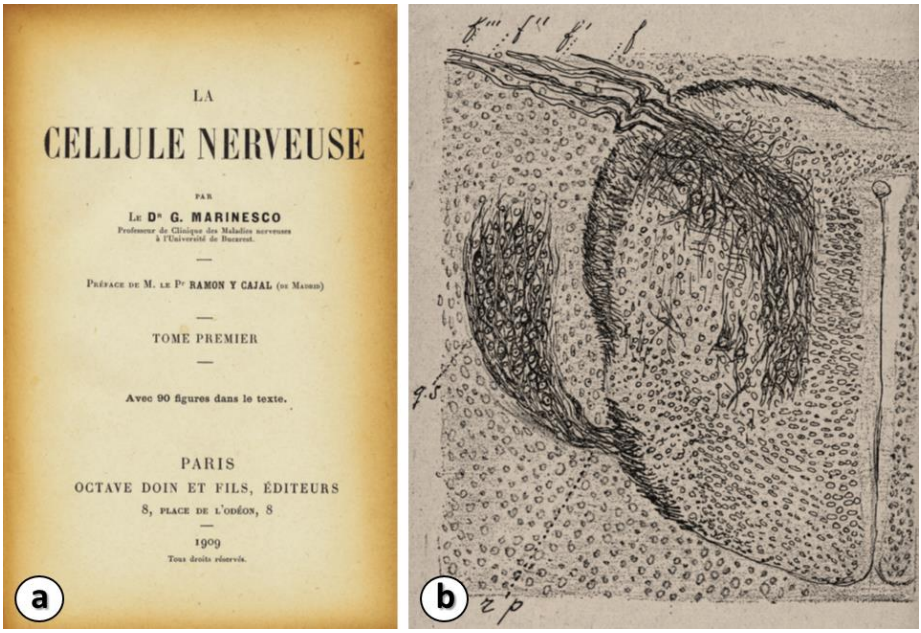

Fig. 3. *La Cellule Nerveuse*, published by G. Marinescu in 1909 (7) (a). Transversal section of a histological preparation showing the nervous fibrils. Chick embryo at six days of incubation. f – ventral roots, gs – spinal ganglion, rp - dorsal root (adapted after *Le Cellule Nerveuse* (G. Marinescu, 1909) (7) (b) (public domain).

Regarding the paranuclear corpuscles, small acidophilic inclusions present in the nuclei of pigmented neurons of the *substantia nigra* and locus *coeruleus*, Marinescu also described them in humans (10) (later named *Marinesco bodies*). He also found that they are more abundant in adults and elderly compared to young people, and also absent in children (7).

An entire chapter of the first volume was dedicated to neuroembryology (7), in which he reviews the knowledge of the time on this subject, to which he adds personal observations that do not depart from the vision of some of his mentors: Santiago Ramón y Cajal and Wilhelm His (1863-1934). One of the theories involved the existence of two types of cells in the neural tube or neuroepithelium: the germ cells that Marinescu considers neuronal precursors and the epithelial

cells that will generate the glial support. Marinescu's neuroembryology studies were largely based on chicken embryos, mice or even human embryos and fetuses (2). In addition, Marinescu also noted in his work that all neurons are not born at the same time, a phenomenon now known as a temporal gradient of differentiation (2).

The second volume of *La Cellule Nerveuse* contained Marinescu's contribution to the histopathology of the nervous system and in which he focused on two entities considered to be important for the neuropathology field: *chromatolysis* and *neuronophagia* (2, 8). He differentiated between the central chromatolysis that appeared in the cell body of the neuron after axon sectioning and the peripheral chromatolysis that could be observed in primary lesions of the nerve cell produced by traumatic or toxic causes (2).

In his experimental studies in rabbits, Marinescu also made observations on cell injuries secondary to nerve sectioning. In other experiments on small animals such as guinea pigs, cats or frogs, he also observed that trauma of the nerve centers leads to initial necrosis and that the neurons do not regenerate, while blood vessels and neuroglia proliferate (2).

Professor Marinescu was also a pioneer in the field of neuronophagia, concluding after multiple studies of chromatolysis and granular fibrillary degeneration, that oxidative stress is a major contributor to the process of neuronal aging (3). He introduced the term *neuronophagia* and demonstrated that phagocytes are not glial cells, but mesoderm-derived mobile cells located near the neuron or migrating from the blood vessels. Later, he assimilated them with microglia (11).

The Nervous Cells's preface was written by Santiago Ramón y Cajal (3), who wrote a laudatory preface: *honorable colleague and learned friend, Professor Marinesco is also an insightful observer and a strong and tenacious supporter of the experimental method* and *that his activity is undeniable, his fruitful research in the difficult field of the histology of the nervous system has earned him a reputation and authority more than enough to impose his own book on the attention and praise of the learned world* (translation of the authors) (7).

Professor Marinescu died in 1938 and on his tombstone is written: *Work ... Sincerity .... Silence ....* (1). He remained for the Romanian medicine as the founder of the School of Neurology, and his entire work together with *La Cellule Nerveuse* was an important pillar in the development of European neurology, which we should remember today.

At the turn of 156 years since his birth, 81 years after his death and 110 years since the publication of the *La Cellule Nerveuse* (1909), we wonder what is today's the inheritance of Gheorghe Marinescu. Of course, his name is closely related to the succulent hand in syringomyelia, to the Marinesco-Sjögren syndrome, to the first descriptions of lesions in the *niger locus* of Parkinson's disease (2), to the more than 1500 works in the field of neuroanatomy, neuropathology, neurophysiology, histochemistry (12), but especially because of his monumental work in the field of neurocytology and neuropathology of the nerve cell and his studies in the field of chromatolysis and neuronophagia - *La Cellule Nerveuse* (2).

In 1951, the anatomist Murray Barr said that *La Cellule Nerveuse, together with Cajal's better known Histologie du Système Nerveux de l'Homme et des Vertébrés, are*

major chapters in the neurocytologist's Old Testament (13).

Beyond these, Marinescu has left us a legacy of humanity. During World War I he offered himself as a volunteer at the Salpêtrière Hospital in Paris, where he cared of wounded soldiers with Pierre Marie. Later, for his humanitarian sacrifice, the French government granted him the title of *"Officer of the Legion d'honneur"* (5).

Three days before his death, Professor Marinescu wrote his own testament in which he mentioned*: No flower, no speech; those who loved me used the money for poor children and good words to encourage the suffering. Do not forget that those who are living in poverty and even in misery are too numerous, that those with money, those who are enriched by neon means live from the exploitation, in one way or another, of those who work. Leaving for the world from which no one has returned, I would not upset anyone, but the truth must be said: too much injustice is in the blessed country of Romania! It is due to the ease or haste with which the vital problems of the homeland were solved. The lack of true citizenship education and the feeling of duty, as well as immense pride or some passing ambitions have given rise to many social anomalies* (14).

CONCLUSIONS

Gheorghe Marinescu represents a European and international personality in the field of neurology and neuropathology. His works together with those of Ramon Y Cajal (1852-1934) represent the fundamental element in the development and understanding of the neurological sciences. In this domain, the keystone is his work published in France, 110 years ago.

ADVERSE CHILDHOOD EXPERIENCES IN RELATIONSHIP WITH EATING DISORDERS (Abstract): Studies indicate that patients with eating disorders report a history of childhood adverse experiences more frequently than the general population. Childhood abuse is reported by a significant proportion of people with eating disorders, with recent research highlighting other forms of child abuse, such as physical and emotional abuse, which may have consequences for later adult health. The association between childhood traumas and eating behaviors is very complex, leading to an increase in body mass index, obesity, metabolic and mental disorders. Bullying is a common childhood experience, with long-term psychosocial consequences and affecting eating behavior. Moreover, parental divorce and parental bonding have been implicated as important risks factors for eating disorders. In conclusion, it may be clinically useful to consider all abusive experiences in the evaluation of patients with eating disorders. Also, recognizing all these facts provides a clear opportunity for early intervention which may help prevent the development of eating disorders in traumatized people. **Keywords**: ADVERSE CHILDHOOD EXPERIENCES, TRAUMA, EATING DISORDERS, CHILDHOOD, POST-TRAUMATIC STRESS, EATING BEHAVIOR.

Adverse childhood experiences (ACE) are traumatic or stressful events exposed to a child that can continue to have long-term negative health effects throughout the course of that child's life (1). There are six categorizes of ACE: physical abuse by an adult in the household, sexual abuse by a family member, sexual abuse by a non-family member, a dysfunctional household caused by the use of drugs or alcohol in the family and witnessing physical abuse by a family member on another family member (2). Others include emotional abuse, failing to provide the necessities (food, medical care, good hygiene) and being the care of a member of the family having a physical or mental illness (3).

Various studies have found risk factors contributing to a child having ACE such as gender, socio-economic status, family type (single parent, adopted child) and the environment they grow up.

The consequences of such traumatic events are linked with self-induced harm to health, antisocial behaviors, a faster development of chronic diseases and premature death (4). ACE during childhood was related to chronic disease later in life and a strong relationship was identified between ACEs and risky behaviors like drinking alcohol,

consuming drugs or eating disorders.

Eating disorders represent a complex, multifactorial pathology, determined by biological, family, psychosocial and psychological factors (5). The lifetime prevalence of eating disorders in adults is about 0.6% for *anorexia nervosa* , 1% for bulimia nervosa and 3% for other eating disorders, disorders that are often chronic, relapsing and devastating. Numerous studies indicate that patients with eating disorders report a history of childhood trauma more frequently than the general population (6).

Freud said that events that occur in the first 6 years of life are particularly important for the rest of one's life, and from this point of view, adverse childhood experiences are associated with an increased risk for acute or chronic psychosocial disorders in adult life (7). Adverse childhood experiences are surprisingly common, generally unrecognized and may begin to show damage through somatization and illness even during childhood (8).

Moreover, several studies have documented an association between traumatic events in children and the development of obesity in life, finding that, out of a sample of adult patients seeking surgical treatment for obesity, about one-fifth were exposed to sexual and physical abuse and more than a third witnessed violence. In addition, other childhood events such as separation from mother or father or marital problems have been associated with an increase in obesity in adulthood (9).

Recognizing these facts provides a clear opportunity for early intervention, as it is demonstrated that what happens in childhood usually lasts a lifetime, like the traces of a child on soft cement, and in this case, time will not heal the wounds, but it will hide them (8).

CHILDHOOD TRAUMA AND EATING DISORDERS

Trauma is any event, usually an unusual one, that harms the body, self or spirit. It covers a wide range of painful experiences, including traumas that involve the physical, sexual, mental or emotional part of our being. The combination of these traumas is called adverse childhood experiences (ACE). If the trauma is accepted as real and the experience of the victim or survivor is validated and its expression sustained, its short-term effects, known as acute traumatic stress, can be expressed, processed, ameliorated or "metabolized" in a healthy way, so that in the end there are few or no harmful effects. In contrast, if the reality of the traumatic experience is denied or invalidated by the victim or other close members (such as family, friends, or help professionals), then the person may not be able to fully heal the adverse effects of the trauma. In order to heal from these traumas, the experimenter must be able to endure the pain associated with it and must remember the trauma well enough to name it accurately, the memory being a key to resolving the effects of the trauma (10).

Childhood traumas have been associated with a number of serious long-term psychiatric sequelae (including depression, alcohol and drug use, anxiety, post-traumatic stress disorder (PTSD), sexual disorders - especially in cases of sexual abuse, self-destructiveness, personality disorders), but in the past decade, clinicians and researchers have considered the possibility that childhood abuse and trauma, especially sexual abuse, may be a strong antecedent of eating disorders (11).

Childhood abuse is reported by a significant proportion of people with eating disorders, with recent research highlighting

other forms of child abuse, such as physical and emotional abuse, which may have consequences for later adult health (12). Also, child abuse promotes the development of mental disorders (mood disorders, post-traumatic stress disorder, substance use disorders, or clinical dimensions related to suicidal behavior, such as impulsivity or aggression), which in turn can lead to eating disorders (6).

Childhood trauma could lead to short-term post-traumatic symptoms, turning into obsessive-compulsive symptoms (such as obsessive fear of weight gain, extreme food concerns, body image and vomiting) in the longer term. Also, many researchers have suggested the need to elucidate the psychological mechanisms linking childhood trauma to subsequent eating disorders. Some investigators reported that depression is a significant mediator between childhood abuses and disordered eating in students, while others reported that anxiety and dissociation were important mediators, but that depression was not. In addition, obsession has been shown to be a predictor of bulimic symptomatology, and obsessive-compulsive traits could also be considered as an important mediator between childhood trauma and eating disorders.

A considerable amount of research has targeted childhood traumas as a risk factor predisposing to the development of eating disorders in adolescence or adulthood, but most research has focused mainly on forms of sexual abuse (5).

CHILD SEXUAL ABUSE AND EATING DISORDERS

Sexual abuse refers to sexual contact or behavior between a child and an older person, the explicit constraint being a frequent but nonessential feature of these experiences (5). There is no knowledge about the types of childhood trauma that are associated with the clinical characteristics and severity of eating disorders, some studies suggest a higher severity of eating disorders in cases of physical and/or sexual abuse, while others do not (6). For example, childhood sexual abuse may be associated with *bulimia nervosa*, whereas links with *anorexia nervosa* and other binge eating disorders are less clear (12).

Some studies consider that sexual trauma is a distal factor in the development of eating disorders - it does not directly cause the development of eating disorders but can precede the onset for a significant period. Based on the literature, it appears that there are two main etiological pathways between sexual assault and eating disorders: first is the survivor's negative perception of her body-including body dissatisfaction, shame and fear of future sexual trauma) and second is the need of a sexual trauma survivor to cope with psychological difficulties (such as failure of the average expected environment, need for control, coping with psychological diagnoses and regulation of emotions (13).

A literature review of the correlation between sexual abuse and eating disorders revealed that approximately 30% of patients with eating disorders had a history of sexual abuse (14). Results of another study indicate that the prevalence of childhood sexual abuse among hospitalized patients with *anorexia nervosa* is high, and these patients have reported higher mental disorders, including higher levels of depression and anxiety, lower self-esteem, greater interpersonal problems and more severe obsessive-compulsive symptoms compared to patients who had no history of childhood sexual abuse. Also, patients with a history

of sexual abuse have reported significantly more severe psychopathology of eating disorders (15).

The history of physical, emotional and sexual abuse in childhood is linked to all types of eating disorders, arguing that it can be both a reaction to abuse and a strategy to cope with the aversive states that result from childhood physical and sexual abuse. It has been found that a history of sexual trauma can increase body awareness and dissatisfaction, promoting eating behaviors and eating disorder symptoms. It has also been found that the incidence of bulimic syndrome in adolescence is up to five times higher among those who have experienced sexual abuse in childhood. Alternatively, childhood traumatic experiences can lead to disorders in the metabolism of norepinephrine, dopamine, serotonin, and endogenous opiate systems, all involved in the regulation of eating behaviors. However, the association between childhood traumas and eating behaviors is probably much more complex, leading to an increase in body mass index, obesity, metabolic and mental disorders (12).

A study of 10-15-year-old girls found that sexual abuse significantly predicts impulsivity and that impulsivity provides the strongest mediation between a history of childhood sexual abuse and purging and/or restricting eating behavior. Thus, sexual abuse has proven to be a predictor for impulse regulation and perfectionism. Another study found that sexually abused anorexic subjects had a higher degree of perfectionism than non-abused subjects, thus being more concerned with avoiding failure (5).

For men, sexual abuse is probably underreported because of the greater shame and stigma that accompanies men's abuse unlike women`s abuse, and because of underreporting, there seems to be a smaller number of men with a documented history of sexual abuse. Most perpetrators of sexual abuse are men; therefore, men who are victims of sexual abuse may develop issues related to sexual orientation and/or fear of experiencing sexuality. Through disordered eating, especially anorexia, men struggling with these problems can deny natural hormonal mandates as a solution to their crisis of sexual orientation. Studies showed that men are less likely than women to engage in bulimic "typical" compensatory behaviors, such as vomiting or laxative abuse; having at the same time more inclination to use excessive exercise as a compensatory method for controlling weight and body shape. The use of assessment tools, which emphasizes compensatory behaviors, binge eating habits, attitudes toward food and emotional triggers in men, would probably improve the accuracy of reporting by men, as well as lead to the development of appropriate interventions (14).

Thus, sexual trauma precedes eating disorders at the same rate as other psychiatric diagnoses and, therefore, may be just one of the many precursors of eating disorders. At the same time, sexual trauma can be a catalyst for mental distress and eating disorders can only be a manifestation of symptoms. It is also possible that there is a biological or neurological vulnerability that initiates an individual on the etiological pathway from a sexual trauma to a diagnosis of an eating disorder (13).

CHILD PHYSICAL ABUSE AND EATING DISORDERS

Physical abuse refers to bodily abuse of a child by an older person, predisposing a risk of or resulting injury (5). Studies have found an association between any form of

abuse and bulimia nervosa or binge eating disorder, but not *anorexia nervosa* - which seems to be related only to the childhood physical abuse. Other environmental factors, such as socio-cultural restrictive *anorexia nervosa*, genetics could be a major factor, possibly more important than environmental and family agents for children (16).

Physical abuse in children seems to be a more important factor in developing the distortion of the body image, its importance exceeding that of sexual abuse. Physical abuse, laxative abuse, and the binge-purge subtype *anorexia nervosa* are a considerable risk factor for the severity of the distorted body image, and their presence worsens the prognosis of the eating disorder. The differences between sexual abuse and physical abuse in terms of their role in the development of body image distortion must be due to the difference between the abuser's acceptances of the body during the abuse (17).

According to a study, when comparing groups of patients with eating disorders, 45% of those who had a history of physical abuse had more severe psychopathological symptoms, especially symptoms of anxiety and substance-related disorders, compared with patients without a history of abuse. Other studies found that if they were studied from the other hand, the appearance of self-destructive behavior was the factor that correlated highly with sexual and/or physical abuse in the history of eating disorders (5).

From previous surveys, it seems that about 5% of children between the ages of 6 and 12 have been physically or sexually assaulted and 10-15% of them have heard or seen such cases. Children who are sexually or physically assaulted feel intense helplessness, often being anxious or nervous. The assault can frequently lead to the so-called daily state of trance, when dissociative mechanisms such as detachment of the body are used to ease the trauma, and this can subsequently lead to rejection of the patient's own body, problems with representing the body's image distortion. During this process models of identification or rejection may appear, the victim of aggression may become an abusive parent herself and, depending on her personality, coping patterns, family conditions and interpersonal skills, she may behave more harshly (by showing herself self-destructive behavior and torture itself), for example by developing an eating disorder. Considering those mentioned, further studies are also needed to decide whether physical abuse plays a specific role in the development of eating disorders and which mediation factors are responsible for this effect (17).

CHILD EMOTIONAL ABUSE AND EATING DISORDERS

Emotional abuse refers to verbal aggression affecting the child's sense of well-being or any humiliating, derogatory or threatening behavior towards a child by an older person (5). Emotional abuse was the only type of abuse constantly linked to the symptoms of eating disorders; the emotional disturbance being positively associated with the symptoms of eating disorders. This highlights the importance of evaluating a history of emotional abuse, in addition to questions assessing the experiences of sexual or emotional abuse of children, which are often more common in clinical practice (16).

Emotional abuse may also increase the severity of eating disorders. It is assumed that specific genetic and/or epigenetic fac-

tors and induced emotional regulation may directly promote the occurrence of eating disorders, but it remains unclear what factors underlie the association between childhood trauma and eating disorders (6). Other studies have found an association between any form of abuse and bulimia nervosa or binge eating disorder, but not *anorexia nervosa* - which seems to be related only to the childhood physical abuse. Other environmental factors, such as socio-cultural influences, may play an essential role in the development of *anorexia nervosa* and especially in restrictive *anorexia nervosa*, genetics could be a major factor, possibly more important than environmental and family agents for children (16).

Emotional abuse has been shown to be a predictor of ineffectiveness, interceptive awareness, and impulse regulation, being the only form of childhood trauma that clearly predicts psycho-pathology in female students (5). Also, childhood emotional abuse was a predictor of bulimic symptoms and plays an important role in the development of psychological difficulties, including eating disorders and may be more traumatic than physical abuse (18). Kent and Waller (19) explained that childhood emotional abuse was a risk factor in the development of eating psychopathology, given the evidence of the links between childhood emotional abuse and self-esteem.

Another study also indicates that childhood emotional abuse is a predictor of "interoceptive awareness" (5). Traumatized individuals were deficient in "interoceptive awareness" for internal physiological and psychological conditions because they have often failed to develop the capacity to differentiate between complex internal states. Therefore, they often expressed their behavioral emotions rather than verbally, because they had difficulty expressing their feelings in words. In addition, the finding that emotional abuse is a predictor of impulse regulation was consistent with the idea that survivors of childhood abuse might turn into self-destructive and self-injurious behaviors, such as purging and vomiting, compulsive sexual behavior, compulsive risk, taking and using psychoactive drugs, to relieve stress and to regulate their internal emotional states, in the absence of the internal self-soothing capacity (20).

Because emotional abuse is likely to occur at a higher frequency than other types of abuse and may be perpetuated by multiple people simultaneously, the potential impact of emotional abuse on children should be viewed as seriously as other forms of children abuse (16). Also, a history of childhood abuse in people with eating disorders is associated with increased use of drug treatments, but with poor outcomes. Thus, both early detection of abuse and ongoing assessment for eating disorders are needed (11).

CHILDHOOD BULLYING AND EATING DISORDERS

Bullying is a common childhood experience with lasting psychosocial consequences because these victims are at an increased risk for physical health problems, behavioral and emotional problems, suicide, psychotic symptoms and weak school achievements; victims who attack others (so-called bully victims) having the worst results. Eating behavior can be affected by bullying for several reasons: bullying can increase one's perceptions of one's body, either directly by teasing about one's weight/appearance or indirectly, by its effects on one's overall self-esteem and emotional problems. The bullies, like vic-

tims and the aggressive victims, had increased results for eating disorders, even though they were perpetrators and probably saw the intimidation as a way of accessing resources. More surprisingly, observed associations were not attenuated in models that highlight the preexisting status, which suggests that experience of bullying itself may affect subsequent behaviors (21). Also, bullying, emotional symptoms, restricted eating and bodily dissatisfaction were all correlated, and emotional symptoms were found to significantly mediate the relationships between verbal intimidation and bodily dissatisfaction in girls, but not boys. Studies suggest that the experience of being verbally intimidated causes adolescent girls to be at a risk of developing emotional problems that can then lead to dissatisfaction in the body (22). In addition, involvement with bullying, as a victim, perpetrator or both, has lasting negative, educational, physical, social and emotional consequences for certain groups of young people (for example, those who are gay, lesbian, overweight or disabled), report higher rates of victimization than other young people (23).

There is growing evidence that victimization is related to either obsessive-compulsive behavior or bodily dysmorphic disorder. This pathology refers to a concern for an insignificant or unimaginable defect of the physical aspect that leads to the impairment of social or professional functioning. Although most individuals with body dysmorphic disorder are concerned with a part of the body (for example, nose, hair), some are concerned about the whole body, considering it is weak, is too small or is not muscular enough.

Nothing is known about the individual or social risk factors that lead to the development of this disorder, but the literature suggests that those who suffer from this disorder have suffered more abuse in childhood. The victimization rate of 21% of childhood bullying mentioned by body builders is comparable to the rates reported on community samples of children in primary schools, but higher than those of children in secondary school. It has been reported that women who were victims of rape as adolescents or adults were more often involved in compulsive dumbbells (24).

Few studies have highlighted the effect of bullying on adolescent women's psychopathology, namely body image difficulties and eating behavior problems. However, a study has revealed that this effect is mediated by shame of body image and self-criticism. Also, a number of studies have shown the relationship between being a target of negative interactions focused on the physical aspect (for example, weight and appearance-related teasing) and eating and body image issues; but peer victimization can have a deleterious effect on eating behavior even when not specifically focused on the physical aspect. Other studies have shown that these extremely negative experiences can have a persistent negative impact on body image and nutrition. In fact, patients with eating disorders often report experiences of being bullied by their childhood and adolescent peers (25).

There is considerable evidence that victims of bullying have a significantly higher rate of psychiatric problems and children who are bullied are often targeted because of perceived characteristics, such as being physically weak, differing in physical appearance, lacking assertiveness, being restless and having little or no friends. The autobiographical accounts of successful bodybuilders and the spontaneous reports

of bodybuilders in this study suggest that being a victim of bullying as a schoolboy and feeling weak and pushed around them can lead to bodybuilding (24).

PARENTAL BONDING AND EATING DISORDERS

The family plays an important role in the development of eating disorders, including *anorexia nervosa* and bulimia nervosa, studies focused on the overprotection of mothers and the indifference of fathers (26). The parental connection has been defined as the parental contribution to the parent-child relationships and is usually evaluated using the *Parental Bonding Instrument*. The maternal and paternal contribution to bonding is realized along two dimensions: care (varies from affection, emotional warmth, empathy and closeness, to emotional coldness, indifference and neglect) and overprotection (varies from control of parental ties and eating disorders, overprotection, intrusion, infantilization and prevention of independent behavior, to allow independence and autonomy (27).

The Parental Bounding Instrument score showed that patients with eating disorders and self-destructive behavior perceived that they received poor paternal care, more than half of these patients feeling that their father had "no affective control". Thus, it supported the hypothesis that the family environment of patients with eating disorders and self-destructive behavior is more complicated than that of patients with eating disorders without self-destructive behavior, in that patients with eating disorders without self-destructive behavior have conflicts with their mother, while patients with self-destructive behavior often have conflicts with their father (26).

A study conducted in a group of adolescent schoolgirls indicates that shame/defect and dependency/incompetence schemes act as perfect mediators in the relationship between parental care, maternal overprotection and symptoms of eating disorder. These results provide additional support for the link between family functioning, early adaptation schemes and symptoms of eating disorders, highlighting the importance of low parental care and maternal overprotection. Low levels of parental care can lead to the development of beliefs that one is flawed and not loved while high levels of maternal over-protection can lead to the growth of a child who believes he or she is unable to handle day-to-day responsibilities independently and in a competent manner. Theoretically, the combination of these early adaptation schemes and the presence of dysfunctional assumptions related to nutrition, weight and shape may contribute to the development of an eating disorder (28).

Parental divorce has been implicated as an important risk factor for eating disorders, with higher rates of divorce being observed in people with bulimia nervosa. Divorce provides an increased risk of an eating disorder (e.g., unspecified eating disorder, *bulimia nervosa* and *anorexia nervosa*) and the associations between divorce and disordered eating extend to community evidence, such as bodily dissatisfaction, control behaviors of weight (for example, diet, exercise) and binge eating. Body dissatisfaction is linked to depression and generally suggests that individuals who are depressed have an increased level of bodily dissatisfaction. This may help explain why the body's dissatisfaction, but not other forms of disordered eating, has shown unique gene-environment interaction effects. Depression is associated with

parental divorce and there is some evidence that childhood separation events increase the risk of depression only if the latent genetic risk is presently high). In addition, stress factors prior to divorce (marital discord, separation of parents) can affect the inheritance of disordered eating more than the divorce itself (29).

Scientific evidence suggests that eating disorders are multi-determined: individual vulnerabilities, family structure and dynamics can all interact in a social setting, which exposes the adolescent to a great weakness. Eating disorders in adolescence may be related to the failure or difficulties of separation in the individual during childhood, difficulties arising from disrupted parent-child relationships. Also, eating disorders usually develop among individuals in dysfunctional parent-child relationships: bulimics and, to a lesser extent, anorexic people, perceive their families as conflicting, hostile, disturbing, and denying the child's emotional needs (30).

CONCLUSIONS

The paper indicates that most respondents reported at least one adverse childhood experience and about one-third of adults experienced at least two adverse childhood experiences in childhood. This finding suggests that an ACE should warn the clinician to evaluate the patient for a history of exposure to other forms of domestic abuse or dysfunction (31). Numerous studies have shown the role of trauma in the development of psychopathology in adulthood. Psychiatric comorbidity rates are higher in patients with eating disorders with a history of childhood trauma (6). The lifetime prevalence of affective disorders in eating disorders is between 25% and 80%, most patients with eating disorders often feel lonely and desperate (32).

However, few studies have evaluated the links between psychiatric comorbidities and basic symptoms of eating disorders in patients who have experienced childhood trauma. It was found that maltreatment was not associated with most lifetime psychiatric diagnoses in patients with binge eating disorders, although specific associations were observed for post-traumatic stress disorders and alcohol use disorders. Another study found that depression fully mediated the associations between some forms of childhood trauma and eating psychopathology. Our results suggest that the links between ED severity and physical abuse as well as sexual abuse may be mediated by the presence of one or more psychiatric comorbidities (6).

Given the above, how can we prevent adverse childhood experiences from affecting so many people? The answer can be multiple. For example, professional health organizations may consider addressing the physical and mental health of their members, including recovering from the harmful effects of any adverse childhood experience. Healthcare companies should pay for adequate short and long-term treatment of the adverse effects of childhood experiences on trauma survivors, which would save them money in the long run. Also, each training program for health care professionals should include information about the effects of trauma, such as child abuse or other adverse childhood experiences, how to ask about them, and what to do with a patient who has suffered this type of trauma. Parents should stop treating their children as if they were their property, and instead give them compassion and love, not shame and fear. In addition, more monetary and political support should be given to organizations work-

ing to prevent child abuse (10).

It may be clinically useful to consider all abusive experiences in the evaluation of patients with eating disorders. Treatment options will be better understood and applied when the role of different forms of childhood trauma in eating disorders is more firmly established.

Finally, the findings that certain forms of childhood trauma are predictors of eating disorders and that depression is a significant mediator suggests that early intervention for childhood trauma and the resulting depressive symptoms may help prevent the development of eating disorders in traumatized people (5).

THE IMAGING EVALUATION OF TYPICAL AND ATYPICAL CALCIFICATIONS IN DIFFERENT ANATOMICAL REGIONS STUDY IN BRASOV, ROMANIA (Abstract): Calcifications in different anatomical regions were identified by using ultrasound exam, radiography, mammography, and computer tomography, according to the anatomical region investigated. **The aim** of this research is to highlighting and evaluating typical and atypical calcifications in the organs of different anatomical regions, correlating them with age and pathology, finding the best imaging methods for detecting calcifications according to the anatomical region examined. **Material and methods** This was a prospective study was conducted for 2 months in 2018, in a private hospital, on 1338 patients of different ages, with or without symptomatology, who were randomly assigned to the Department of Radiology and Medical Imaging for the following types of examinations: radiography, computer tomography, ultrasound exam and mammography. **Results:** Calcifications found by imagistic methods were evaluated in the following anatomical regions: head, neck, thorax, abdomen, and pelvis. A database was generated where all data was collected and analyzed with SPSS 20.0 software. Various situations have been highlighted by anatomical regions. **Keywords:** AGE, CALCIFICATION, ANATOMICAL REGIONS, ULTRASOUND EXAM, RADIOLOGICAL EXAM, MAMMOGRAPHY, COMPUTED TOMOGRAPHY.

Calcifications may be physiological or pathological and may occur at different ages.

We will briefly describe a general assessment of these calcifications in some anatomical regions considered in the study to understand the importance of their identification, their benign and malignant characterization, and their association with the age and type of imaging examination. The most common intracranial calcifications were highlighted in the pineal gland (a calcification over 1 cm in diameter under the age of 9 years may be suggestive of a neoplasm), habenula, choroid plexus (frequently evident in the middle portion of the lateral ventricles), basal ganglia (calcifications are 0.3-1.5% and increase with age), falx, tentorium cerebella (affects 10% of the elderly population), sagittal sinus and petroclinoid ligaments (related to elderly degeneration) (1). The most common neoplastic calcification are: oligodendroglioma (70-90%), craniopharyngioma (50-80%), germ cell neoplasms and pineal neoplasms (60-80%), central neurocytoma and primitive neuroectodermal tumor (50-70%), ependymoma (50%), ganglioglioma (35-50%), dysembri-

yonic neuroectodermal tumor (20-25%), meningioma (20-25%), choroid plexus papilloma (25%), medulloblastoma and low grade astrocytoma (20%), and pilocystic astrocytoma (10%) (2).

In the chest region calcifications are highlighted in the pulmonary parenchyma, mediastinum, hilar and mediastinal lymph nodes, pleura chest wall, vascular, or any combination of these structures. Gross calcifications are evident on a conventional chest radiograph, but smaller calcific deposits are better evident on digital radiograph, computer tomography and high-resolutions CT (3). Pulmonary calcifications are the common asymptomatic finding discovered on chest X-ray and Chest CT (4).

In breast calcifications high-quality image and magnification on mammographic views are essential for the detection and evaluation of breast calcifications. It is important to differentiate the microcalcifications of benign origin (which increase their frequency with the age) from those that are suspected to be malignant, since 55% of non-palpable cancers are of ductal carcinoma form in situ. Distributions diffuse/scattered are a characteristic of benign calcifications. Regional distribution can signify a 26% probability of malignancy. Grouped/clustered calcifications more than 5 per 1 cm (this being the lower limit) indicate a suspicion of malignancy. Linear distribution calcifications may indicate a 60% and the segmental distribution a 62% malignancy probability (5). The positron emission mammography investigation is useful for assessing patients with suspected focal calcifications present on mammography. This is absolutely necessary for identifying invasive carcinomas and high-grade ductal carcinoma in situ. It becomes useful for avoiding false negative results of stereotactic biopsy (2).

For region of abdomen and pelvis calcifications can be visualized in normal and abnormal abdominal structure. They appear on radiographs and CT images as radiopaque or hyper-dense lesions (3).

On ultrasound, calcification appears as hyperechoic, posterior acoustic shadowing depending on the size and characteristics of the surface structure of calcification. The color Doppler twinkling artifact is a helpful sign for identifying small calcifications and thus can improve diagnostic (6). Computer tomography is regarded as gold standard for the identification of calcified lesions. Normal structures that calcify are costal cartilage, mesenteric lymph nodes, pelvic vein clots, and prostate gland. A high content of calcium in abnormal structures may indicate pathology of pancreas, renal parenchymal tissue, blood vessels and vascular aneurysms, gallbladder fibroids (leiomyoma). The same is true for biliary, renal, bladder calculi, appendicolith, and teratoma. Gynecological calcifications, fibroids, can become calcified and appear as rounded structures of varying sizes and locations in the pelvis (1). Frequently encountered abdominal and pelvic tumors often present a typical calcification pattern (7).

Miscellaneous Tumors appear as: calcifications with punctate pattern are unusual in the gastrointestinal stromal tumors (3-10%); solid pseudopapillary neoplasm is a peripheral curvilinear, rim (eggshell), punctate pattern of calcification. Calcification is seen as single or multiple form, it can be located peripheral, central or internal septa of tumor and can be punctate (round), amorphous (irregular), curvilinear or rim (eggshell) (8). Calcifications in the pancreas were found in 10-20% of cases

with a peripheral, curvilinear pattern or septal location, including punctate and coarse (amorphous) pattern. Intratumorally calcification can differentiate pancreatic neuroendocrine tumor (20% show calcifications) from adenocarcinoma (2%).

Calcifications in the liver are a rare form of the biliary neoplasm, such as solitary cyst adenocarcinoma, which is well encapsulated. These are rarely found but have been reported in 47% of the cases.

Calcifications in the appendix can be curvilinear, peripheral, and can occur in <50% of cases in mucinous adenoma, low-grade mucinous neoplasm, and mucinous adenocarcinoma. Mucinous neoplasm appears as a round or tubular cystic mass; wall thickening, and the irregular shape raise suspicions of malignancy (9).

Calcifications can be seen in all types of neurogenic tumors with various patterns. The tumor usually occurs in the retroperitoneum of the adrenal gland (10).

Castleman disease is an uncommon benign lymph proliferative disorder. Hyperplasia of lymphoid follicles is located in thorax in 70% of cases, 10-15% in the neck, 10-15% in the abdomen, retroperitoneum and pelvis. Calcifications patterns include punctate, peripheral, central, arborizing calcifications (8-11,12)

MATERIAL AND METHODS

This was a prospective study, conducted for a period of 2 months in the Department of Radiology and Medical Imaging of a private hospital in Brasov. The batch consisted of 1,338 patients of different ages who underwent various imaging investigations, namely: radiographic examination, computed tomography, ultrasound scan, and mammography. The devices on which the study was conducted are radiography device - Axiom Iconos R200 - *Siemens*, computed tomography - Somatom Emotion 16 - *Siemens*, ultrasound RS 80 with Prestige - *Samsung*, Logiq S7 - *General Electric*, mammography - Senographe Crystal - *General Electric*. Calcifications found imagistically were evaluated in the following anatomical regions: head, neck, thorax, abdomen, and pelvis.

The age-groups of the patients in the study are not homogeneous; thus, we have calculated percentages distributed according to each anatomical area from the total of persons in each age group.

The distribution of the patient batch by age group is unbalanced; therefore, the percentages distributed to each anatomical area were calculated from the total age group. Independent variables are age categories, while dependent variables are the percentage of people with calcifications in different age groups.

A database was generated where all data was collected and analyzed with *SPSS version 20.0* statistical software. The collected data was processed in Excel, the graphs being generated using Pivot tables. The X^2 homogeneity test was applied to determine whether there are statistically significant differences in the age groups of the patients participating in the study and the occurrence of calcifications in these five anatomical regions.

The purpose of this study was to highlight calcifications in different anatomical regions except limbs, in symptomatic or asymptomatic patients, and correlate them with the pathology and type of examination.

RESULTS

Analyzing the presence of the patients in the batch studied by age groups it was

found that the most representative incidence was in the 51-60 years old age group (28.7% of the patients), followed by the age group 41-50 years - 18.8% and then the group 61-70 years - 16.8%, these age-groups representing more than half of the studied total of patients. The low incidence was highlighted under the age of 30 and over 80 years, with an average of 4.5%. If we consider the distribution of patients depending on whether or not a symptomatology is present, symptoms in different regions were found in 67% of patients. Most of them accused frequent pains in the abdominal and cranial region (for both sexes). In the case of female patient's chest pain was noted, especially in the mammary gland. 33% of patients showed no symptoms; most of these patients came for a routine or regular control sent by an occupational physician.

In terms of gender of patients, a slightly higher (by 1%) incidence in the case of the females was noted (tab. I)

TABLE I

Distribution of patients with and without calcifications by age group

Age group	0-10	11-20	21-30	31-40	41-50	51-60	61-70	71-80	>80
With calcifications	3	6	43	85	185	286	191	105	74
Without calcifications	21	38	55	44	67	98	34	3	0
Percentage with calcifications	12.5	13.63	48.87	65.89	73.41	74.47	84.88	97.2	100

Analyzing the presence of calcifications according to the patients' age, it was found that their age-related linear increase was lower for those under 20, reaching 73% for the age group of 41-50, 97% for the group over 70 years, and 100% for the persons in the group over 80 years.

There is an increasing trend in the number of calcifications in total by age. Different trends have been observed for each anatomical region (fig. 1).

The sample we had was not equally distributed by age category and we took in consideration the percentage of patients presenting calcifications from each age group.

The regression was performed for each anatomical region to analyze age dependency of the anatomical area in the patients presenting calcifications. There was a 91% influence of calcifications on all anatomical regions studied in relation to age. Straights and regression equations have been drawn.

The determination coefficient, R square, for each anatomical region was obtained (fig. 2).

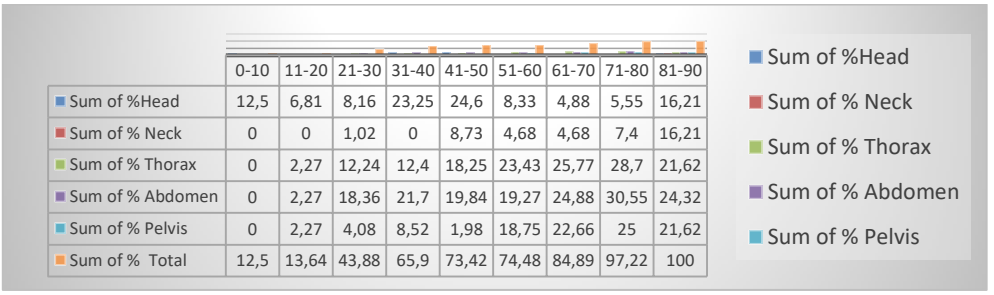

Fig. 1. Percentage distribution of patients according to age group and anatomical region

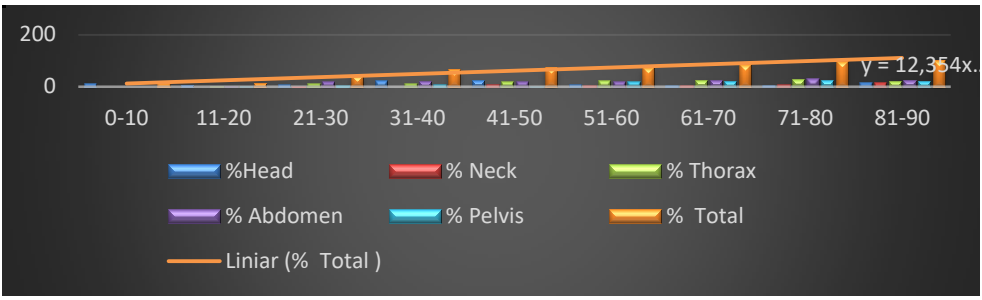

Fig. 2. Linear regression for each anatomical region

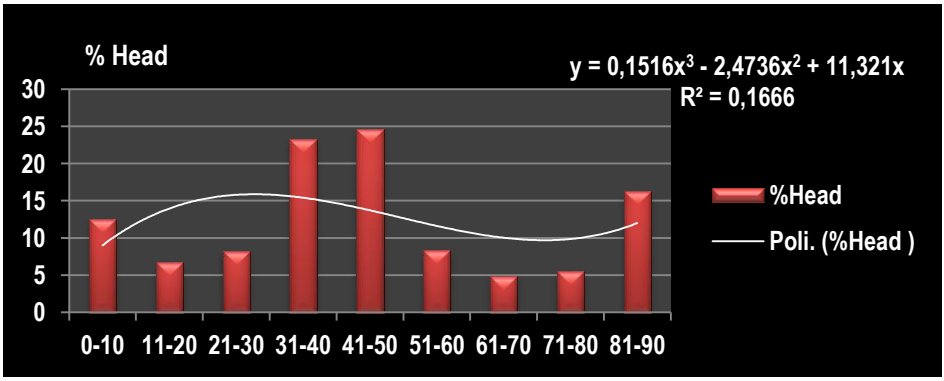

Fig. 3. Polynomial regression between head region and age

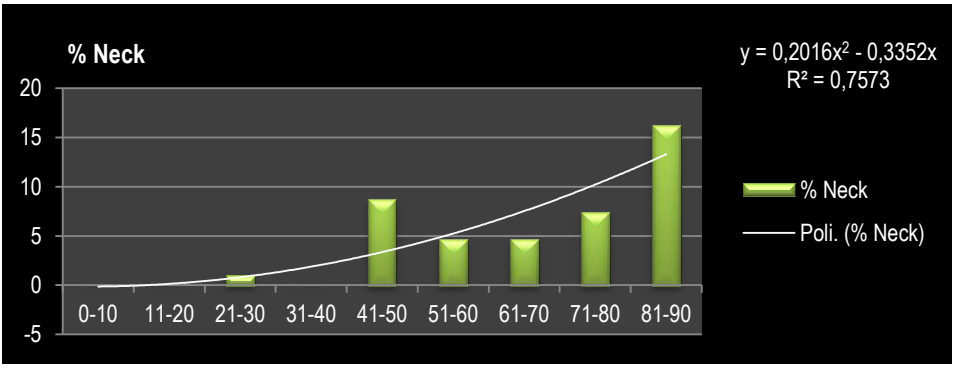

Fig. 4. Polynomial regression between neck region and age

R square shows how much age influences the presence of calcifications in various anatomical regions.

R square in the Head region has an influence de 16% in what calcifications are concerned, but it is inversely proportional with the increase of age. Between 30-50 years there is the highest peak (a mean of approximately 24%). The peak may be influenced by stress factors (fig. 3).

As far as the neck region is concerned, the number of people presenting calcifications increases with age, but a maximum appears around the age of 41-50 of 75% (fig. 4).

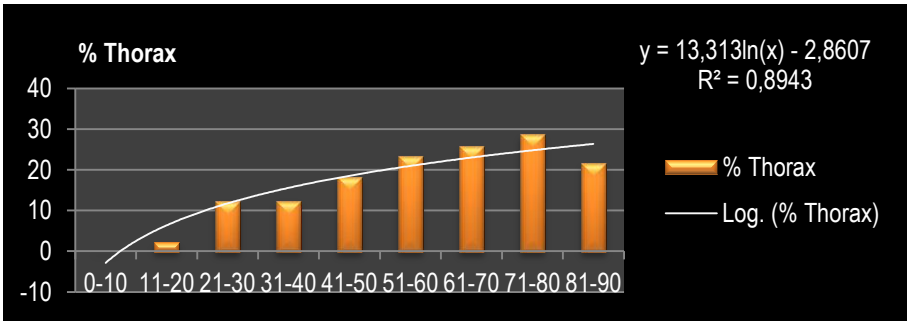

Fig. 5. Logarithmic regression between thorax region and age

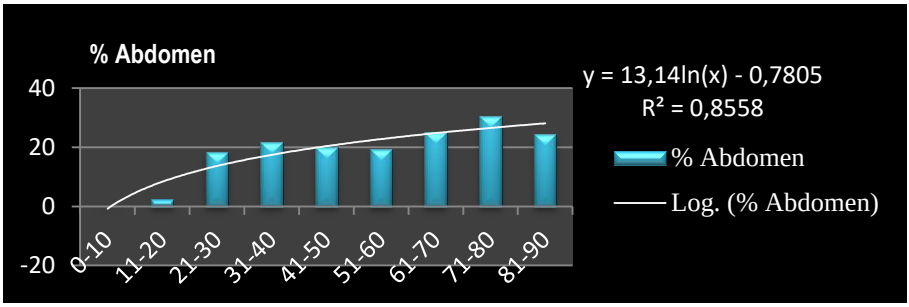

Fig. 6. Logarithmic regression between abdominal region and age

In the case of the thoracic region, we have the strongest correlation of 84% and a proportional increase with age of calcified individuals, but a reduction for the patients over 80 years due to the small number of persons in this age-group who came for an imaging evaluation in the period of the study (fig. 5).

In the abdominal region, we also have a close relationship of 85% and a rise of calcifications with age, but it falls in the case of the patients over 80 years. This may be due to the small number of patients who were present in relation to the other age groups, as was also the case for the results concerning the chest region (fig. 6).

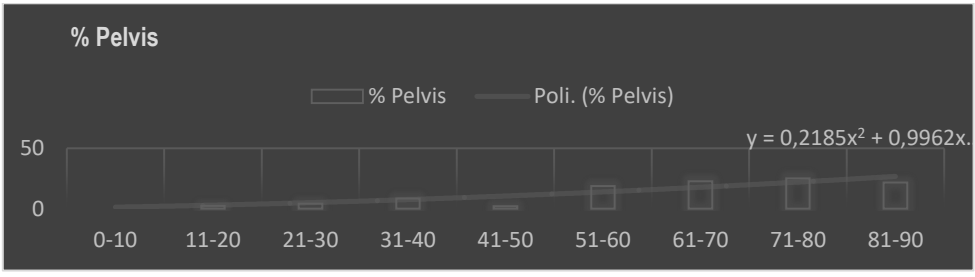

Fig. 7. Logarithmic regression between the pelvic region and age

In the pelvic region we have an 80% correlation, an increase proportional to the age of people with calcifications, similar to the chest and abdominal region (fig.7.)

TABLE II
Determination coefficient R square for each anatomical region

Anatomic region calcifications / Age	Head	Neck	Thorax	Abdomen	Pelvis
R Square	0.1666	0.7573	0.8943	0.8558	0.8094

By considering the R square determination coefficient for each anatomical region, an influence of age in the occurrence of calcifications in different anatomical regions was found. In the head region, there is a small influence (16%) of age on calcification. Age dependence in the occurrence of calcification in the neck is 75%. The risk of calcification at thorax level is higher, 89%. For the pelvis and the abdomen, the percentage is 85% and 80%, respectively (tab. II). Calcifications were less numerous in the cranial region due to its smaller volume and number of organs located in it than in, for example, the thoracic and abdominal region. Calcifications were more frequent in the elderly patients, but the number of patients who were part of the study, especially those over 80, was smaller. Using SPPSS we showed that there are statistically significant differences between the groups analyzed by X^2 = 25,674; p = 0.001, meaning that age does affect calcifications. Age influences cranial calcifications, as seen in the observed and expected counting table. It is statistically demonstrated that calcifications occur depending on the group of participants and on the age category. DATA-Weight Cases were weighted. By this statistical method, for each anatomical part we have determined the ages in which there is a tendency for the occurrence of more calcifications than is normally expected. In this study, the presence of typical and atypical calcifications in different organs, age groups, case correlations and pathology were analyzed.

DISCUSSION

In the head region, we identified the presence of calcifications in the young age up to 40 years in the pineal gland, habenular commissure, falx, tentorium cerebellum, and a case of congenital calcifications in the *Sturge Weber* syndrome. Between 40-50 years, calcifications occurred in the lenticular nucleus and in one case of cerebral tumor recurrence. After the age of 50, the presence of atheromatous calcium plaques was observed in the intracranial cerebral vessels, associated with the presence of the pathology. Calcifications in the neck region have been noted frequently in nodules in the thyroid gland (with a peak between 40-50 years), increasing also with age at the neck artery. Until the age of 40, calcifications in the thoracic region were revealed in the form of small calcifications at the level of mediastinal adenopathy, wall calcifications in the costal cartilage, while after 40 years at the level of some lung or solitary nodules, solitary or multiples. Calcifications in the abdominal region were surprisingly frequent in the 21-30 age group.

The presence of kidney and gall bladder stones and the environmental influences were more often observed among female patients in this group. After 40 years calcifications have been revealed in the spleen, adrenal gland, pancreas, calcifications associated with the history of pathology, in the male sex these being commonly encountered in the pancreas. At the age of 11-20 years, physiological calcifications in the prostate were present, the pathological calcifications being more frequent after the age of 50. At females, there have been calcifications in the genital

sphere, especially calcifications in the uterine fibromatous nodules. In both genders, calcifications of normal structures, namely pelvic vein clots -phlebolith, and at the level of some vessels were noted. Imaging investigations are useful tools for woman after 50, especially in the postmenopausal period.

CONCLUSIONS

In the revised literature, calcifications were highlighted in all anatomical regions, in most organs by different methods, without correlating them with the pathology of other organs, we tracked their incidence and correlated with age and certain pathologies existing only in the analyzed region. Highlighting intracranial calcifications by CT examination requires their description in terms of location of size and shape, which are necessary for a correct diagnosis and their correlation with age and neurological signs for true diagnosis and therapy. The method is original because the random group determined by collecting imaging investigations for two months, considering five anatomical regions, demonstrates the dependence of the number of patients with calcifications on their age, but also the particularities of each anatomical area. Using imaging investigation and correlating with patient's symptomatology or age is an accessible and noninvasive tool for screening neoplasms and benign tumors, with an impact on group ages people, especially on the elderly. In the future studies we intend to correlate the presence of calcifications in certain organs with their pathology in other anatomical regions.

CHILDREN LANGERHANS CELL HISTIOCYTOSIS DIAGNOSIS PROBLEMS (Abstract) : Langerhans cell histiocytosis is a group of idiopathic disorders characterized by the proliferation of cells of the mononuclear phagocyte system and the dendritic cell system. From the clinical point of view there are 3 forms of histiocytosis encountered in child pathology : acute, disseminated called Abt-Letterer-Siwe (it usually affects children under 2 years of age), eosinophilic granuloma and the intermediate clinical form called Hand-Schuller-Christian disease. We present the case of a premature born child that had, even from the day she was born, a rash disseminated on the entire surface of the body associated with enlarged lymph nodes, hepatosplenomegaly and thrombocytopenia. The diagnosis of Langerhans cell Histiocytosis is difficult to establish and this case is an example that confirms it. Therefore, we present the difficulties in diagnosing this case and its particular evolution. **Key words** : HISTIOCYTOSIS, CHILD, RASH

PERCEPTIONS OF COVID-19 VACCINATION AMONG HEALTHCARE PROFESSIONALS IN ROMANIA

PERCEPTIONS OF COVID-19 VACCINATION AMONG HEALTHCARE PROFESSIONALS IN ROMANIA (Abstract): The first case of new coronavirus infection was reported first in the Wuhan city area from China in December 2019. The virus spread rapidly worldwide, produced an atypical cluster of pneumonia, was known all over the world as Coronavirus Disease 2019 (COVID-19) and, in Romania, first case was registered on the 26th of February. In Romania, the number of cases increased constantly, and a lot of healthcare professionals were infected with SARS-CoV-2. Aim: The aim of our study was to assess the opinion of healthcare professionals on the situation generated by the COVID-19 pandemic and to find what treatment against COVID-19 (a future vaccine, hydroxychloroquine) would be accepted by healthcare professionals. Material and methods: We used an online survey that was conducted from April 15th, 2020 to May 15th, 2020. The survey was developed using Google Forms and included 15 items. The respondents were recruited from health professionals (physicians, pharmacists and nurses), and future health professionals. Results: a number of 529 healthcare professionals were included in the study from different cities of the country. A total of 365 respondents (69%) agreed with the COVID-19 vaccine. Differences in accepting the vaccination against COVID-19 coverage by profession ($p=0.011<0.05$) were found. Conclusions: Based on the assessment of the current COVID-19 situation globally, the COVID-19 vaccines must be inoculated to the healthcare workers, but training on vaccination and compulsory measures may be needed in order to achieve better coverage. **Keywords**: COVID-19, VACCINATION, HEALTHCARE PROFESSIONALS.

In Wuhan city area from China was reported appearance since December 2019 of a new coronavirus which was named later Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2). This virus produced an atypical cluster of pneumonia, spread rapidly all over the world and known worldwide as Coronavirus Disease

2019 (COVID-19) (1). On 30 January 2020 to an international concern (PHEIC) the COVID-19 emergency was declared the sixth public health emergency by the World Health Organization (WHO) (2). On 11 March 2020 WHO declared COVID-19 officially pandemic (2). The symptoms associated with COVID-19 include cough, fever, diarrhea, shortness of breath, myalgia, sore throat, headache, and fatigue. Complications of the disease include pneumonia, acute severe respiratory distress syndrome, renal failure, or even death in certain cases (3, 4). In Romania, the first case of COVID-19 was registered on 26th of February, in the contact of an Italian infected person. In the next days, this case was followed by a few cases every day, until March 10, when the number of cases increased. A lot of Romanians (around 5 million) are working in Western Europe (around 1 million in Italy, but also In Spain, France, Germany, United Kingdom) (5). In all these countries and other western Europe countries, SARS-CoV-2 rapidly spread, the lockdown of most economical activities and tens of thousands of Romanians returned home. This emigration creating a huge potential for imported cases. Vaccines and treatments for COVID-19 are currently in development (6). Several studies reported that hydroxychloroquine has antiviral and prophylactic activity against SARS-CoV-2 (7-11).

In countries with weaker healthcare systems, prevention and supportive care are highly recommended (2, 12), as suggested by WHO director-general Tedros Adhanom Ghebreyesus (2). The COVID-19 pandemic causes mental health problems and panic for the public (13-15). Misinformation about this epidemic and myths, executive orders to quarantine travelers, and travel bans might affect the public's psychological health (14, 16, 17). Health literacy (HL) could help individuals and healthcare systems achieve a better lifestyle, quality of care, treatment decisions, disease management, and health outcomes (18, 19). Studies showed in previous pandemics that healthcare professionals were under strong stress from spreading the disease to their families, fear of becoming ill, and the heavy workload (20, 21). The threat of the disease can cause depression, anxiety, and stress (22-25).

This study aimed to assess the opinion of health professionals and future health professionals on the situation generated by the COVID-19 pandemic and to find what treatment against COVID-19 (a future vaccine, hydroxychloroquine) would be accepted by health professionals and future health professionals.

MATERIAL AND METHODS

Ethical Issues

This research was approved by the Academic and Scientific Ethics and Deontology Committee of the University of Medicine and Pharmacy in Craiova (Registration No. 26/2020) according to the European Union Guidelines (Declaration of Helsinki). All the respondents provided electronic informed consent starting with the first question of the survey.

Study design

The survey was developed using Google Forms and included 15 items. It was conducted from April 15th, 2020 to May 15th, 2020, and the respondents were recruited from health professionals and future health professionals. The online survey was anonymous and confidential. It was composed of three main sections: demographic characteristics, attitudes, and beliefs towards COVID-19 and treatment against COVID-19. The demographic section was com-

posed of seven items exploring age, gender, city, profession (physicians, pharmacists, nurses, medical students), the instruction level, the specialty, type of hospital (designated hospital vs. non-designated hospital). Three items about the treatment against COVID-19 composed the treatment section. Five items about beliefs were included in the third section.

Statistical Analysis

Continuous variables (age) were summarized as mean and standard deviation (SD). Kolmogorov-Smirnov Test was used to verify the normal distribution of continuous variables. Categorical variables were summarized as frequencies and percentages. Chi-Square tests or Fisher's exact tests were performed to compare categorical variables as appropriate. The analysis was performed with IBM *SPSS for Statistics version 25* (IBM SPSS, Armonk, NY). The significance level was 0.05.

RESULTS

A number of 529 health professionals and future health professionals were included in the study from different cities of the country, 362 of which were female (68.4%), with a mean age of 35.34±10.75 years (range: 21-66 years). The health professionals were the most of them from Craiova (309, 58%) and Bucharest (44, 8%). From the physicians, 115 (33%) were senior specialists, 114 (33%) specialists, and 117 (34%) residents. From the pharmacists, only 4 (5%) were senior specialists and 7 (9%) specialists.

A number of 154 (45%) physicians worked in a designated COVID-19 hospital and only 8 (26%) were nurses. From the pharmacist's respondents, 5 (6%) of them worked in a designated hospital, and the rest of them in a community pharmacy (tab. I).

TABLE I

Health professionals' characteristics

	Physicians (n=344)	**Pharmacists** (n=84)	**Nurses** (n=31)	**Medical students** (n=66)	**p-value***
Gender Female	207 (60%)	75 (89%)	26 (84%)	53 (80%)	p<0.001
Age (years old) <30 30-40 41-50 51-60 >60	 91 (27%) 137 (40%) 58 (17%) 40 (12%) 17 (5%)	 52 (62%) 24 (29%) 6 (7%) 2 (2%) 0	 5 (17%) 10 (33%) 11 (37%) 4 (13%) 0	 58 (88%) 8 (12%) 0 0 0	p<0.001
Working place Designated COVID-19	154 (45%)	5 (6%)	8 (26%)	-	p<0.001

*Chi-square test

In second table we define the attitudes about vaccination and COVID-19 treatment during the administration of the questionnaire.

A total of 365 respondents (69%) agreed with the COVID-19 vaccine. Differences in accepting the vaccination against COVID-19 coverage by profession ($p=0.011<0.05$) were found. In particular, physicians and medical students were more likely to accept COVID-19 vaccination than the other professions.

The medians of age (the distribution of age is not normal after One-Sample Kolmogorov testing) are the same across categories of accepting COVID-19 vaccination (p=0.138). Differences in accepting the vaccination against COVID-19 coverage were also found by depressed state (p<0.001): the depressive one was more likely to accept the vaccination.

The level of satisfaction with the protection measures taken did not influence the opinion on vaccination (p=0.094>0.05), nor knowing anyone infected with COVID-19 (p=0.316) or coming in contact with COVID-19 (p=0.063).

Fear of getting infected (p<0.001) and working in a designated hospital (p=0.023) made the difference in accepting COVID-19 vaccination.

Gender did not influence the opinion of acceptance of COVID-19 vaccination (p=0.664).

TABLE II

COVID-19 treatment opinion

N (%)	Physicians (n=344)	Pharmacists (n=84)	Nurses (n=31)	Medical students (n=66)	p-value*
If there was a vaccine against COVID-19, would you be vaccinated ?					p=0.011
Yes	242 (70%)	53 (53%)	19 (61%)	51 (77%)	
Do you know anyone infected with COVID-19?					p<0.001
Yes	161 (47%)	16 (19%)	8 (26%)	8 (12%)	
Do you think you have come in contact with COVID-19?					p<0.001
Yes	177 (51%)	24 (29%)	15 (48%)	5 (8%)	
Are you afraid of getting infected?					p<0.001
Yes	185 (54%)	48 (57%)	17 (55%)	49 (74%)	
What do you think about the protection measures in place ?					p<0.001
Yes, I am satisfied	212 (62%)	44 (52%)	22 (71%)	38 (58%)	
Do you feel sad / depressed during this period?					p=0.06
Yes	163 (47%)	32 (38%)	16 (52%)	41 (62%)	
Would you take hydroxychloroquine prophylactically?					p=0.03
Yes	87 (25%)	9 (11%)	9 (29%)	8 (12%)	
Would you recommend hydroxychloroquine?					p<0.001
Yes	186 (54%)	16 (19%)	11 (35%)	22 (33%)	

*Chi-square test

From all the respondents, 301 (57%) had a fear to get infected with SARS-CoV-2, from which the most were medical students (74%).

A total of 316 (60%) respondents considered satisfied with the available protection measures in hospitals/pharmacies. There is significant difference between the responses: the pharmacists were least satisfied with the protection measures taken, and the nurses the most satisfied.

255 of the respondents (48%) were sad/depressive during the COVID pandemic. Also, there are no differences in the depressive fillings between healthcare professionals from designated and non-designated hospitals (p=0.202). No differences were found in the depression level between feminine and masculine healthcare professionals (p=0.843). From healthcare

workers, nurses have the highest level of sadness/depression (52%).

Even if the treatment with hydroxychloroquine were controversial at the time of the survey, 113 (21%) from the respondents would administer prophylactically and 236 (45%) would recommend hydroxychloroquine in the treatment schedule.

DISCUSSION

This survey showed all factors that influence the acceptance of COVID-19 vaccination. More than 70% of the doctors and future doctors agreed with the vaccination, while 53% of pharmacists and 61% of nurses agreed with vaccination. Training on vaccination and compulsory measures may be needed in order to achieve better coverage. COVID-19 vaccination might be useful in the case of additional subsequent waves occur (26).

Regarding the sadness / depression during this period, all the healthcare professionals had a medium level, without differences between them or between the genders. The COVID-19 pandemic may be stressful for healthcare professionals because of the fear and worry about your health and the health of the loved ones, and the changing in live patterns. Furthermore, healthcare workers feel under pressure, particularly if they have not been involved in a similar situation. Other studies proved that rates of anxiety and depression were higher for female healthcare workers and nursing staff (27).

According to our results, a high percentage of the respondents are afraid of getting infected with COVID-19: 54% of physicians, 57 of pharmacists, 55% of nurses, and 74% of medical students. It is an extremely high percentage for medical students, despite the fact that only 8% of medical students thought that they have come in contact with COVID-19.

Community pharmacists were vital healthcare professionals during the outbreak, being on the frontline of public health with direct access for the patients (28-31). 52% of the pharmacists' respondents were satisfied with the protection measures provided. This small percentage is due to the fact that no Romanian organization or authority has dealt with ensuring the protection of pharmacists in the first month of the outbreak. The pharmacists themselves and their employers provided personal protective equipment. In the community pharmacies, the employers ensured that pharmacists are getting adequate breaks between shifts to ensure the disinfection of the space. Also, appropriate measures were taken to prevent the spread of infection and several modifications were made to the environment and work processes. Protection guidelines on COVID-19 were issued for the pharmacists by the *International Pharmaceutical Federation* (32) and other editorials (33). In Romania, the community pharmacies were encouraged to receive the prescriptions through email/electronic transfer. According to FIP, in order to expand capacity for mass immunization against COVID-19 when vaccines are available, the Romanian Government should consider enabling pharmacists to immunize adults (34).

Although the proved benefit of hydroxychloroquine is very limited against COVID-19 (34, 35), its demand was very high and there were problems in providing them to patients who were being treated with them for other chronic diseases, like rheumatoid arthritis, lupus, *porphyria cutanea tarda*. The percentages of recommend hydroxychloroquine (54% by doctors) or taking prophylactically (25% by doctors) are too high given that available clinical trials have not demonstrated that either of hydroxychloroquine or chloro-

quine are clearly effective. Furthermore, a study suggested that treatment with hydroxychloroquine could increase the risk of patients dying from COVID-19 (36), even if it has been retracted and more trials have recommenced.

The strength of this study is the big number of healthcare professionals, including healthcare workers and medical students. The main limitation was the large number of physicians among healthcare professionals that responded to our survey.

CONCLUSIONS

Based on the assessment of the current COVID-19 situation globally, the COVID-19 vaccines must be inoculated to the healthcare workers.

The moderate percentage of Romanian healthcare workers that agree with COVID-19 vaccination demonstrate the mandatory measures that may be needed in order to achieve better vaccination coverage, so they must be protected during the COVID-19 pandemic.

RETINAL VASCULAR IMPACT IN SYSTEMIC HYPERTENSION. CASE REPORT (Abstract): We report a case of malignant systemic hypertension in the context of a multifactorial association (chronic kidney disease, hereditary thrombophilia, autoimmune thyroiditis, hyperaldosteronism, infectious optic neuritis) with ophthalmological onset symptoms only, highlighting the interrelationship between the retinal vascular impact and systemic hypertension, as well as between the systemic hypertension and the patient's underlying diseases. The paper presents the case of a 40-year-old female who complained of sudden loss of visual acuity in both eyes. The ophthalmological examination was suggestive for hypertensive neuroretinopathy, but the management of diagnosis and therapy was particularly difficult in the absence of systemic complaints and low patient compliance for a long time regarding the complementary interdisciplinary consultations that were recommended by the ophthalmologist. Confirmation of the diagnosis of hypertensive neuroretinopathy was possible only late in the evolution of the disease, with the appearance of systemic complications of hypertension such as: encephalopathy, cardiomyopathy, and nephropathy. In this context, a plurietiologic determinism was identified: chronic kidney disease, autoimmune thyroiditis, hyperaldosteronism, hereditary thrombophilia, and infectious optic neuritis. The ophthalmologic condition began to evolve favorably anatomically and functionally only after the establishment of pathogenic treatment. In conclusion, we are faced with a complex case that requires a multidisciplinary approach to assess a wide range of diseases, which analyzed separately, can have retinal vascular impact. **Keywords**: AUTOIMMUNE THYROIDITIS, CHRONIC KIDNEY DISEASE, HEREDITARY THROMBOPHILIA, HYPER-ALDOSTERONISM, HYPERTENSIVE NEURORETINOPATHY.

Systemic hypertension is a major cause of worldwide mortality (1). Any target organ can be affected by acute, severe, uncontrolled hypertension, the retina being no exception (2).

Vasoconstriction, arteriosclerosis and increased vascular permeability that occur in systemic hypertension cause retinal vascular damage which is clinically classified in: hypertensive angiopathy, retinopathy

and neuroretinopathy (2,3,4).

The pathophysiological changes in retinal vascular diseases include narrowing of the arteriolar lumen (vasoconstriction), damage of the vascular endothelium, degeneration of the smooth muscle fibers of the vascular wall, leakage of the plasma into the vascular walls that coagulates and produces mural thickening and luminal narrowing (fibrinous necrosis) (4,5,6), hypoperfusion and end-organ ischemia with subsequent target-organ dysfunction (6,7).

The blood-retinal barrier is a selective barrier that restricts the passage of molecules from capillaries to the retina, allowing optimal neural function. In hypertensive retinopathy, the internal barrier (retinal vascular endothelium) is disrupted, while the outer barrier (retinal pigment epithelium) is generally spared (8, 9). The increase in vascular permeability generates nerve fibers layers ischemia (cotton wool spots) and hemorrhages (flame shaped). Hard exudates resulting from lipid accumulations in the hemorrhagic areas, are characteristically arranged as macular star, due to the disposition of Henle fibers that are found only at this level, missing from the avascular foveal area (9, 10, 11).

Papillary edema is the important consequence of hypertension on the optic nerve, the ischemia causing swelling and blurred disk margins and the leakage causing peripapillary hemorrhage and disc edema (5, 9, 10, 11).

CASE REPORT

We report the case of a 40-year-old woman that presented in our clinic for painless decreased visual acuity (VA) in both eyes (OU) with sudden onset and no systemic complaint. The patient had a significant positive family history of type II diabetes mellitus (mother) and systemic hypertension (father). She was smoker and suffered from obesity (BMI = 35 kg/m^2), dyslipidemia and hypothyroidism.

VA of the right eye was 20/100 and 20/40 in the left eye. The intraocular pressure and anterior segment evaluation were normal for OU.

Fundus examination of OU revealed typical elevated and hyperemic papilla with blurred margins and with absent excavation, arteries with irregular caliber, turgid veins, arteriovenous crossings with vein deviation, the presence of cotton wool spots located parallel to the temporal arches and macular star.

Optical coherence tomography (OCT) assessed the macular structural impact and showed in OU an increase in retinal thickness with neurosensory retinal detachment, due to the underlying intraretinal fluid corresponding to the interpapilomacular area. The optic nerve OCT demonstrated an artefactual increase of the retinal nerve fiber layer (RNFL) thickness and the significant decrease of the tomographic parameters of the excavation on OU (fig. 1).

Corroborating the anamnesis, the ophthalmological examination, and the context of the patient's denial of the pre-existence of systemic hypertension, the first stage diagnosis was for OU: Papillophlebitis, Neuroretinopathy of unknown etiology, Papillary edema, Macular edema, and Foveal retinal neurosensory detachment. Consequently, we initiated treatment with nicergoline, acetylsalicylic acid, sulodexide and recommended paraclinical investigations and complementary interdisciplinary consultations: cardiological, hematological, endocrinological, nephrological, neurological and diabetes.

The patient returned to our clinic several times with incomplete, uncertain, or invalid results of the requested interdisciplinary examinations, noting on each ophthalmological evaluation the progression of structural and functional changes, despite the above-mentioned recommendations and the intravitreal treatment with anti-VEGF and anti-inflammatory steroid (figs. 2-5). During the last evaluation (fig. 6), the patient complained of occipital headache, marked decrease in VA and developed an exacerbation of retinal changes with severe alteration of retinal tomographic parameters.

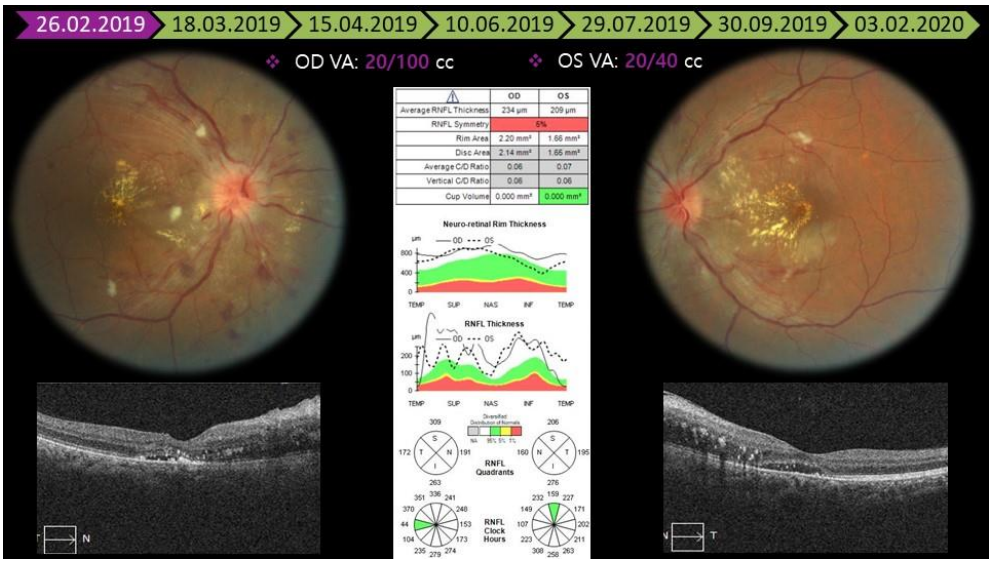

Fig. 1. Ophthalmological aspect at first presentation

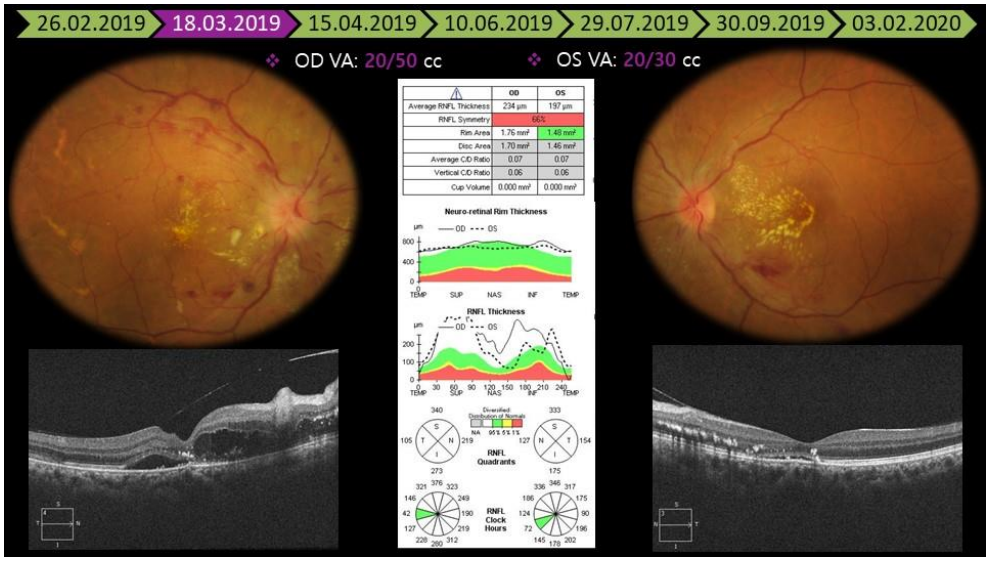

Fig. 2. Progression of structural and functional changes one month after presentation

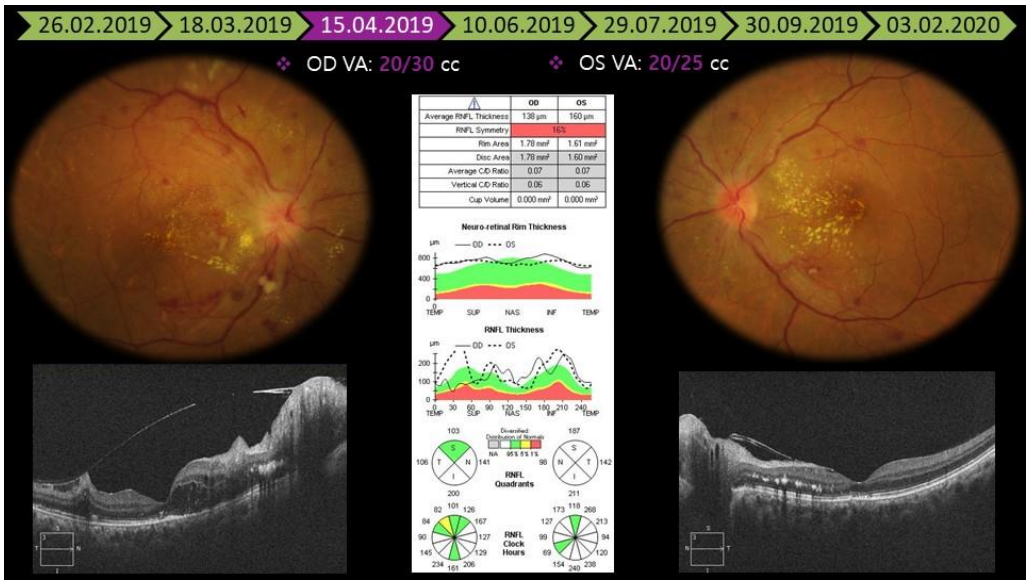

Fig. 3. Progression of structural and functional changes two months after presentation

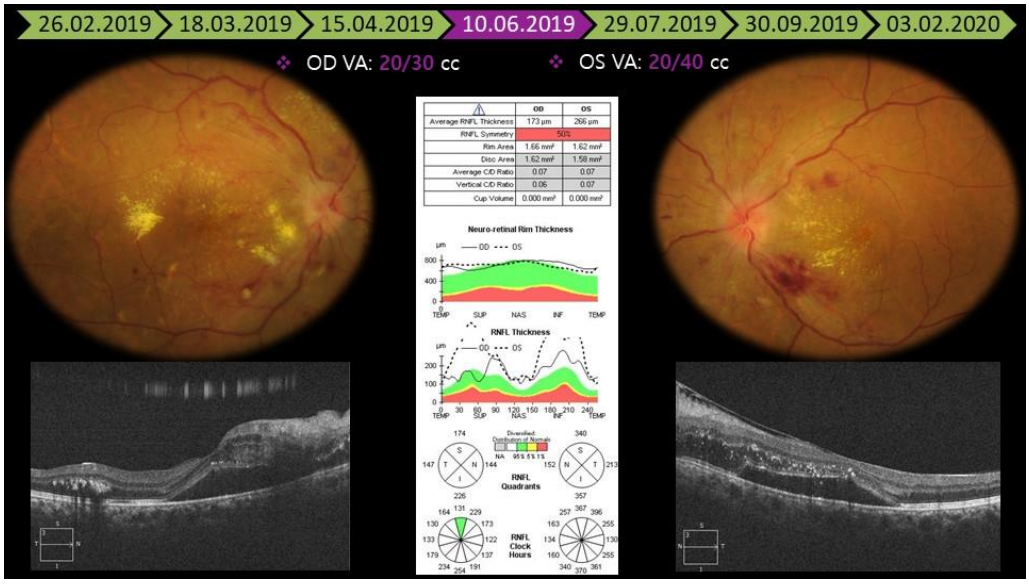

Fig. 4. Progression of structural and functional changes four months after presentation

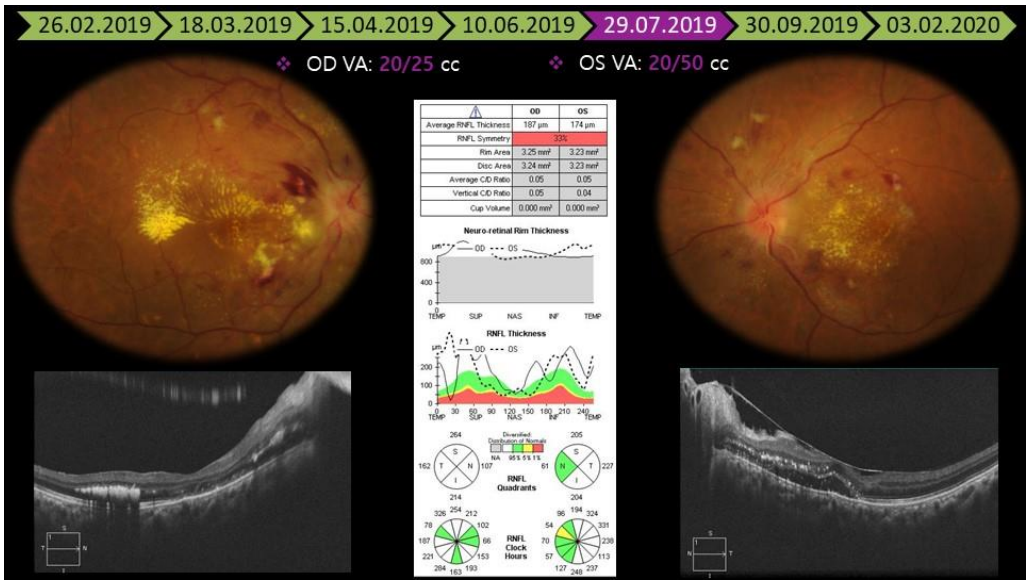

Fig. 5. Progression of structural and functional changes five months after presentation

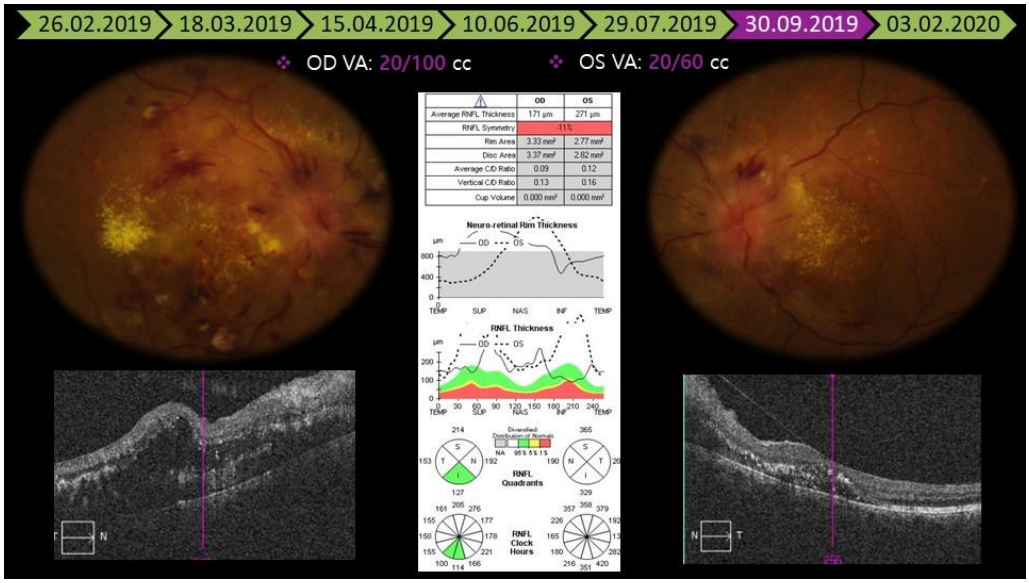

Fig. 6. Exacerbation of structural and functional changes seven months after presentation

Considering the given situation, the patient accepted the multiple interdisciplinary examinations, resulting several diagnoses as: malignant systemic hypertension (250/150 mmHg), hypertensive cardiomyopathy, hypertensive encephalopathy, chronic kidney disease stage G4, hypertensive nephropathy, hyperuricemia, secondary hypertension of endocrinological/renovascular cause, suspicion of prima-

ry or secondary hyperaldosteronism (aldosterone-renin ratio > 3), hypothyroidism and hereditary thrombophilia (MTHFR and PAI-1 genes mutations). The abdominopelvic MRI identified no tumors, urinary metanephrines and normetanephrines were in normal limits and the doppler ultrasound of the renal arteries showed no stenosis. As such, hygienic-dietary recommendations, and medical treatment (clonidine, amlodipine, spironolactone, furosemide, alopurinol and levothyroxine) were instituted, and the blood pressure reached the optimal parameters.

The VA improved in OU and we noticed the remission of the pathological elements: pink papilla with net edges and visible excavation, partial remission of macular exudates and disappearance of the cotton wool spots. The macular OCT revealed in OU the intraretinal fluid resorption, application of the neurosensorial retina and subsequently retinal thickness decrease, but with the appearance of macular atrophy due to ganglion cell complex - internal plexiform layer severe thickness decrease. The optic nerve OCT evaluation found normal optic disc tomographic parameters with normal RNFL thickness in OU (fig. 7).

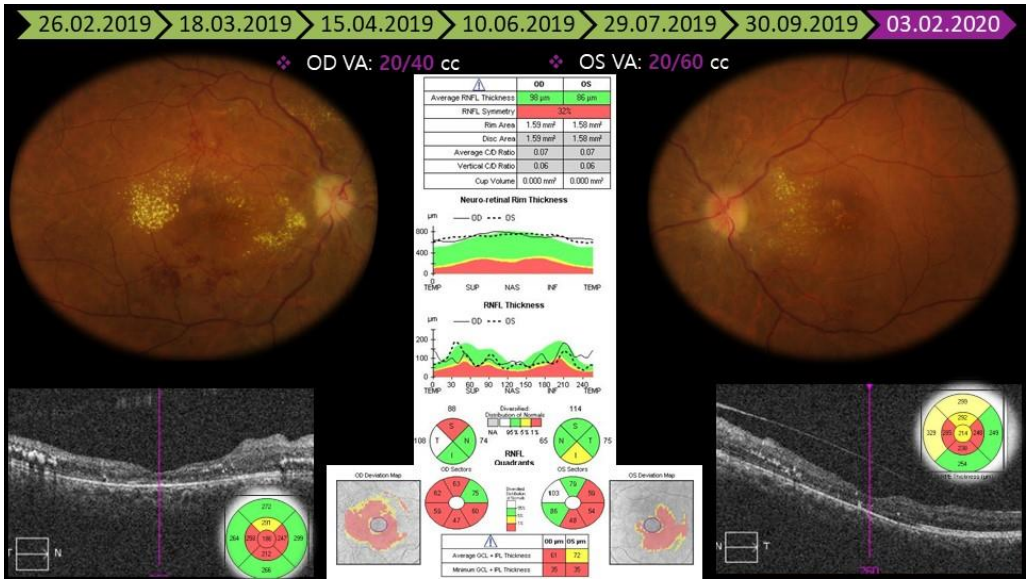

Fig. 7. Favorable ophthalmological evolution

The differential diagnosis of the ophthalmological aspect was done with retinal vascular diseases such as diabetic retinopathy which was excluded by normal laboratory examinations and with retinal vein occlusion (RVO) which could not excluded, it being frequently associated (8,12). It should also be noted that if the neurosensorial retinal application occurs after medical treatment, the diagnosis of hypertensive retinopathy is supported at the expense of RVO, as in the RVO, the outer blood-retinal barrier is affected while in hypertensive retinopathy is spared (9,13).

Regarding anemia and other blood dyscrasias (12), the presence of hereditary

thrombophilia can induce retinal changes.

We also considered other causes of papillary edema (14). The autoimmune or infectious cause were excluded by normal laboratory tests, except for the presence of antithyroperoxidase antibodies (TPOAb) which requires the differential diagnosis between the patient's hypothyroidism and autoimmune thyroiditis, respectively the presence of high titers of anti-Epstein Bar and anti-Varicella Zoster Viruses antibodies that raises the suspicion of a viral optic neuritis. Cerebral MRI was performed to assess intracranial hypertension of multiple causes, establishing the massive diffuse edema of the cerebral white matter which correlated with systemic hypertension and occipital headache led the neurologist to diagnose the hypertensive encephalopathy. Last but not least, we considered arteritis and non-arteritic anterior ischemic optic neuropathies (15, 16, 17) which were excluded by good VA and by the optic nerve aspect (3, 8, 11, 18,).

Secondary systemic hypertension can be caused by: pheochromocytoma, primary/secondary hyperaldosteronism, Cushing's syndrome, renal parenchymal/vascular disease, obstructive sleep apnea, hyperparathyroidism, hyperthyroidism, etc. (12). The patient is currently being evaluated by the endocrinologist and nephrologist.

Corroborating the data obtained so far, we established the positive diagnosis of Hypertensive neuroretinopathy in OU, along with the interdisciplinary diagnoses mentioned above.

The vital prognosis is correlated with multiple systemic complications that can occur over time. Visual prognosis depends on the evolution of the systemic diseases, severe retinal complications comprising retinal artery occlusion (19), RVO, retinal aneurysms, intravitreal bleeding, third and sixth oculomotor nerves palsy, hemianopathic deficiencies, etc. (3, 10, 11, 12, 18).

DISCUSSION

This case perfectly illustrates the retinal vascular impact of systemic hypertension. We would like to point out that many young patients with malignant systemic hypertension may actually present with bilateral vision loss due to serous macular detachment and bilateral optic disc edema (12, 13, 20). The relationship between young age and the retinal changes is consistent with the hypothesis that chronic hypertension, as it occurs in older patients, may have protective effects against the development of acute hypertensive damage (8, 21).

We also note the difficulty in distinguishing between essential and secondary hypertension in the context of renal impairment in this patient (chronic kidney disease stage G4, hypertensive nephropathy, aldosterone (523.5 pg/mL) - renin (107.44 pg/mL) ratio > 3, no renal arterial stenosis, no abdominopelvic tumors and normal urinary metanephrines and normetanephrines). Malignant hypertension is associated with activation of the renin-angiotensin-aldosterone system (RAAS), that plays a key role in the pathogenesis of hypertension. Severe increase in blood pressure would, in fact, lead to the activation of RAAS by microvascular damage and renovascular ischemia, and the increase in the production of angiotensin II would further increase blood pressure, leading to malignant hypertension. As such, we recommend following-up the renal function evolution and performing a renal biopsy if necessary (22, 23).

Hereditary thrombophilia (heterozygote

MTHFR and homozygote PAI-1 genes mutations), may play an important role in the etiopathogenesis of RVO. Smoking, obesity, dyslipidemia (hypertriglyceridemia - 157.6 mg/dL, cholesterolemia - 171.6 mg/dL, high-density lipoprotein cholesterolemia - 41.9 mg/dL and low-density lipoprotein cholesterolemia - 120.3 mg/dL) and the increased value of homocysteinemia (12.7 μmol/L) are also risk factors for systemic vascular thrombosis along of course with systemic hypertension (24, 25). Hyperhomocysteinemia is associated with both venous and arterial thrombosis in all vascular system, especially in the brain, therefore normalization of the elevated serum homocysteine may reduce the risk of a subsequent vascular event (26).

The thyroid gland has well-recognized effects on the cardiovascular system and blood pressure regulation. Blood pressure is altered over the entire spectrum of thyroid disease (27). The patient was already diagnosed with hypothyroidism and the presence of TPOAb was recently confirmed. First, we would like to emphasize that in the case of hypothyroidism and autoimmune thyroid disease there is a state of hypercoagulability given by increased fibrinogen level, factor VII level and activity, and plasminogen activator inhibitor-1 level, that may predispose to RVO (28). Another observation is the possibility of exacerbation of the autoimmune hypothyroidism in the primary hyperaldosteronism that the patient is suspected of (29).

Given the presence of antibodies in serum, both Epstein Bar and Varicella Zoster, viral etiology may be responsible for the appearance of neuroretinitis, as: anterior optic neuritis, also called papillitis (swollen optic disc), retrobulbar optic neuritis (normal optic disc), neuroretinitis (optic disc edema with macular star), anterior ischemic optic neuropathy, etc. (30). Another situation that could be considered would be vascular modification from vasculitis associated with papillary edema, which may pose problems of differential diagnosis. The pathogenesis of ischemia in retinal vasculitis is unclear, but it is suggested to be either thrombotic or obliterant secondary to the infiltration of inflammatory cells (31).

We identified several particularities in these case: the young age of malignant systemic hypertension onset; the ocular complaints were the first manifestations of a systemic disease; a multidisciplinary management was mandatory for the correct and complete diagnosis; the low compliance delayed the multidisciplinary evaluation; and the favorable evolution under pathogenic treatment with good functional and structural recovery.

CONCLUSIONS

We are faced with a complex case of hypertensive neuroretinopathy that requires a multidisciplinary approach to assess a wide range of diseases, which analyzed separately, can have retinal vascular impact.

ARTICULAR CARTILAGE REGENERATION: TISSUE-ENGINEERED CARTILAGE BRINGS NEW HOPE

Articular cartilage is non-lymphatic, non-vascular and non-neural structure and due to this fact is characterized by a limited capacity for self-repair. All traditional cartilage regeneration techniques have certain limitations. The technological leap in tissue engineering has brought hope in the regeneration of articular cartilage. Currently, three strategies are used to achieve "scaffold-cell" tissue regeneration, without scaffolding and without cells. The cell-scaffold construction, in which the seed cells are autologous or stem chondrocytes CaReS®, BioSeed®-C, together with NOVOCART® 3D are present on the medical market and are being the subject of several current clinical studies. Pluripotent stem cells and mesenchymal stem cells from different sources are mainly used for "scaffold cell construction". Cell-free strategies that indirectly use the repair and regeneration potential of stem cells, TruFit and MaioRegen are used in clinical practice. The scaffolding strategy represents a new direction of development, and the results of the short-term repair of the actor's product types are verry encouraging. (Shuangpeng J *et al*. Clinical Application Status of Articular Cartilage Regeneration Techniques: Tissue-Engineered Cartilage Brings New Hope. *Stem Cells Int* 2020; 2020: 5690252).

HIGH RISK PREGNANCY FOR ACHONDROPLASIA AND THE IMPORTANCE OF IgG AVIDITY TEST FOR DATING THE INFECTION WITH *TOXOPLASMA GONDII*. CASE REPORT (Abstract): Achondroplasia is the most common disproportionate dwarfism caused by a mutation in fibroblast growth factor receptor 3 (*FGFR3*). The disease is inherited in an autosomal dominant manner, but 80% of cases are due to a *de novo* mutation. We present a couple consisting of a man with achondroplasia and a woman with normal stature. The man was diagnosed with achondroplasia at 5 years old, on clinical and radiographic basis. At age of 28 the molecular testing by PCR-RFLP confirmed the clinical diagnosis, being detected the G1138A heterozygote mutation in *FGFR3* gene. The couple asks for genetic counseling when woman was pregnant, and the couple was concerned about the possibility of transmission of mutation to children. The woman was tested by TORCH screen and was found positive testing for IgM and IgG antibodies against *Toxoplasma gondii*. The IgG avidity test for *Toxoplasma gondii* indicated the absence of recent infection with this parasite. Thus, the couple decided to continue the pregnancy, but demanded a prenatal diagnosis for achondroplasia. Molecular analyze was done on the DNA extracted from fetal cells obtained by early amniocentesis and the fetus wasn't a carrier of a mutation responsible for achondroplasia. A normal baby was born at term. In conclusion, we present the particularities of a high-risk pregnancy for achondroplasia and the utility of some tests for discrimination between recently acquired and an old infection with *Toxoplasma gondii*. **Keywords:** ACHONDROPLASIA, CONGENITAL TOXOPLASMOSIS, PRENATAL DIAGNOSIS, IGG AVIDITY TEST.

Achondroplasia (AC; OMIM 100800) is the most common form of disproportionate dwarfism. The main clinical signs are small stature, rhizomelic shortening of the limbs, macrocephaly, characteristic dysmorphic features with frontal bumps, flattened nose root, trident configuration of the hands, exaggerated lumbar lordosis (1). Birth prevalence of achondroplasia is 4/100,000 (2).

The disease is caused by mutations in the fibroblast growth factor 3 receptor gene

(*FGFR3*; MIM 134934). AC is transmitted in an autosomal dominant manner. In 80% of cases the mutation in the *FGFR3* gene is *de novo* (3, 4). *De novo* variants are exclusively produced during the paternal meiosis, being associated with advanced paternal age (5). The risk of an individual with AC to have children with AC when the partner is of medium height is 50%. If both parents are diagnosed with AC, the probabilities in the offspring are the following: 50% AC heterozygote form, 25% average waist, 25% AC homozygous form (lethal condition) (6).

Mutations in achondroplasia concern the *FGFR3* gene and all are located in the same region of this gene: the codon 380. The most frequent mutation is G1138A (98%) while in the rest of cases was discovered the G1138C variant. Both mutations generate the replacement of an arginine residue with glycine at position 380 of the protein. For this reason, the penetration of the disease is 100% (6).

The study based on the analysis of EUROCAT (European Surveillance of Congenital Anomalies) registries from 1991-2015 showed a stable, but heterogeneous prevalence in various regions and countries of Europe. In 20.2% of familial cases and 10% of sporadic cases there are associated congenital anomalies. The most important congenital anomalies associated with achondroplasia were anomalies of the nervous system (hydrocephalus 2.3%, Arnold Chiari malformation 0.5%), congenital heart defects (ventricular septal defect 1.6%, atrial septal defect 0.7%, patent ductus arteriosus 0.2%), urinary system (hydronephrosis 1.4%, double ureter 0.2%), omphalocele 0.2%, hypospadias 0.2%, and clubfoot 0.9% (3).

Complications associated with AC that can increase morbidity and mortality are: delayed motor and speech development in children, otitis media with hearing loss, respiratory dysfunction with obstructive sleep apnea, spinal stenosis and compression, dental malocclusions (7).

In AC, the change in quality of life refers to two areas: medical and psychosocial. The first category includes: pain, compromised physical function, overall diminution of functional health status (6,8-10). The second category is referred to: diminished income, less education and less successful employment, decreased self-esteem (8, 11).

Toxoplasmosis is caused by the parasite *Toxoplasma gondii*. It is one of the most common infections of humans worldwide (12). The birth prevalence for congenital toxoplasmosis was 33/100,000 according to European data (2).

Toxoplasmosis can be divided into 4 categories: 1) acquired in the immunocompetent patient; 2) acquired or reactivated in the immunodeficient patient; 3) ocular; 4) congenital (13).

T. gondii infection is asymptomatic in approximately 20% of cases of toxoplasmosis in immunocompetent individuals or shows minor signs (cervical lymphadenopathy or a flu-like illness) (13). Immunocompromised hosts may experience symptoms and severe damage: encephalitis, retinochoroiditis, fetal abortion, splenomegaly and pneumonitis (14).

The presence of the parasite during the pregnancy could generated different complications including vision loss, deafness, intellectual disability, severe developmental delay, neurological deficits. Prenatal treatment reduces the risk of developing these complications (15). Congenital toxoplasmosis can be subclinical at birth in

75% of cases, but over time the described complications could raise (13). In the case of symptomatic congenital toxoplasmosis, the classical triad includes chorioretinitis, intracranial calcifications and hydrocephalus, to which are added other elements of severity such as microcephaly, hepatosplenomegaly, jaundice, convulsions, chorioretinitis (often bilateral), cerebral calcifications, and abnormal cerebrospinal fluid (16, 17).

We present the case of a high-risk pregnancy for achondroplasia in which prenatal molecular diagnosis was made in the fetus and the IgG avidity test for *T. gondii* ruled out a gestational infection, invalidating a suspicion of congenital toxoplasmosis.

CASE REPORT

We present the case of a couple (28 years old, both members) who requested preconception genetic counseling because the man was diagnosed with achondroplasia. The diagnosis of achondroplasia was made on a clinical and radiological basis in childhood (at the age of 5 years), without a molecular test to reveal the gene mutation. The couple was unrelated. The family history was negative for achondroplasia. We discussed the risk of recurrence of the disease in offspring, the possibility of prenatal diagnosis and the need for molecular testing to highlight the mutation in proband.

Molecular testing for proband was requested. The PCR-RFLP technique analyzed the G1138A and G1138C mutations (*FGFR3* gene) associated with achondroplasia. The result of the analysis confirms the clinical diagnosis, the consultant being heterozygous for the FGFR3 G1138A mutation. In the same year, the couple returned for prenatal diagnosis. Molecular analyze was done on the DNA extracted from fetal cells obtained by early amniocentesis (12 weeks of gestation) and the fetus wasn't a carrier of his father's mutation in *FGFR3* or of the other mutation responsible for achondroplasia FGFR3 G1138C (fig. 1).

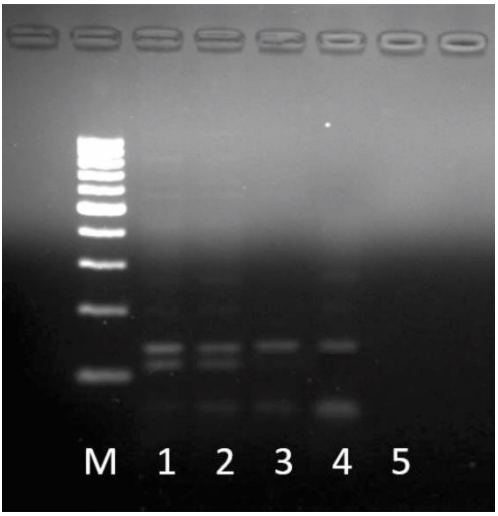

Fig. 1. PCR-RFLP analysis

3-fetus; 4-negative control; 5-water

The pregnant woman was tested by TORCH screen in the first trimester of pregnancy. The results showed that she was positive for IgM and IgG antibodies against *Toxoplasma gondii*: IgG antibodies 436.6 IU/mL (reference values: ≥ 30 IU/mL = positive); IgM antibodies = 0.96 IU/mL (reference values: ≥ 0.65 IU/mL = positive). Under these conditions, the question arose whether there was a risk of congenital toxoplasmosis in the fetus. To assess whether it was a preconception or acquired infection during pregnancy, it was recommended to perform the IgG antibody avidity test. Result of the IgG avidity test using ELFA (Enzyme-linked

fluorescent immunoassay) method was: *Toxoplasma gondii* IgG 82 IU/mL (< 4 negative; ≥ 4 and < 8 equivocal; ≥ 8 positive < 300 old immunity or onset of seroconversion; ≥ 300 recent or persistent seroconversion of an older high level). The avidity index was 0.488 (reference value: < 0.2 low avidity; 0.2-0.3 intermediate avidity; ≥ 0.3 high avidity). The increased avidity index ruled out recent infection (in the last 4 months) with *T. gondii* and thus ruled out the risk of congenital toxoplasmosis.

DISCUSSION

The molecular diagnosis strategy in AC includes as a first test, targeted analysis for the two common pathogenic variants. If the mutation is not highlighted, it can be done in the second stage of the multigene panel that includes *FGFR3* and other genes of interest involved in diseases with which a differential diagnosis can be made on a case-by-case basis (hypochondroplasia, thanatophoric dysplasia, SADDAN syndrome, cartilage-hair hypoplasia and other metaphyseal dysplasia, pseudoachodroplasia) (1, 18). In the case of our patient, the most frequent mutation was confirmed, so it was not necessary to proceed to the second stage of testing.

Pathogenic variant c.1138G>A (p. Gly380Arg) is identified in approximately 98% of patients with AC and variant c.1138G>C (p.Gly380Arg) in approximately 1% of cases (1). Thus, the molecular strategy and the genetic counselling in achondroplasia are easier than in the case of other monogenic diseases characterized by a high genetic heterogeneity (many mutations in the same gene / in different genes) (19, 20, 21).

Genetic counseling is a communication process, provided premarital or post marital, in the situation where there is genetic illness in the family (22, 23). The pregnancy of a couple in which one or both members of the couple are diagnosed with AC is a high-risk pregnancy. If the mutation was detected preconceptionally, the couple may benefit from prenatal or preimplantation diagnosis. Non-invasive prenatal testing could be performed on free fetal DNA cells in maternal blood, but this method is not yet wide used (24). In our case, molecular testing was performed by PCR-RFLP using fetal DNA obtained by early amniocentesis at 12 weeks of pregnancy.

Congenital toxoplasmosis is the consequence of infecting a woman with *T. gondii* in the first trimester of pregnancy or shortly before conception (25). The disease is preventable, treatable and reversible and therefore it is especially important to establish the diagnosis of acute or chronic infection during pregnancy. Treatment in utero during gestation significantly decreased mother-to-child transmission and improved clinical outcome (25-27).

In several European countries including Romania, the TORCH panel is recommended for pregnant women in the first trimester of pregnancy. If TORCH screening reveals IgM and IgG antibodies to *T. gondii*, it is important to distinguish between recent infection and past infection because the risks of congenital toxoplasmosis in the fetus are different and management is different also (fig. 2). *Toxoplasma gondii* - specific IgG avidity testing is an essential tool in establishing this in the immunocompetent host (28).

A high *T. gondii* specific IgG avidity result in 1st trimester is indicative for a past infection (older than 4 months). In our case it was a high avidity and, in this way, we

established that it was a primary preconception infection. When the result of the avidity test shows low or intermediate avidity this is not informative in dating the infection (28) (fig. 3). When the IgG avidity testing is made in the 2nd or 3rd trimester the results are more difficult to interpret because a high avidity is suggestive for past infection, but possibly during pregnancy (fig. 4).

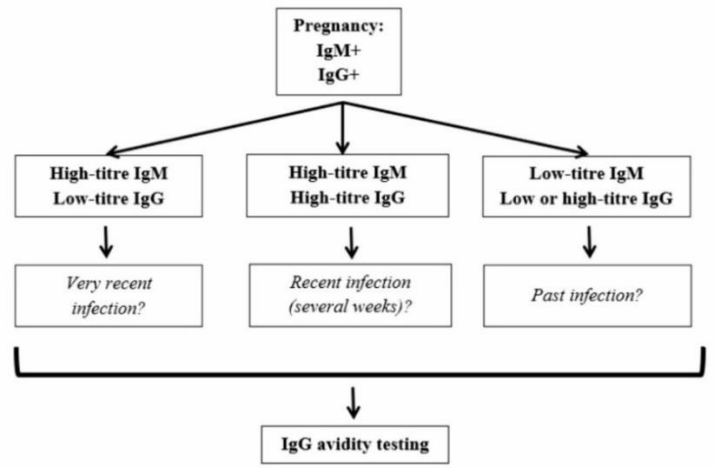

Fig. 2. Study of antibodies titers (Adapted from *Garnaud*, 2020)

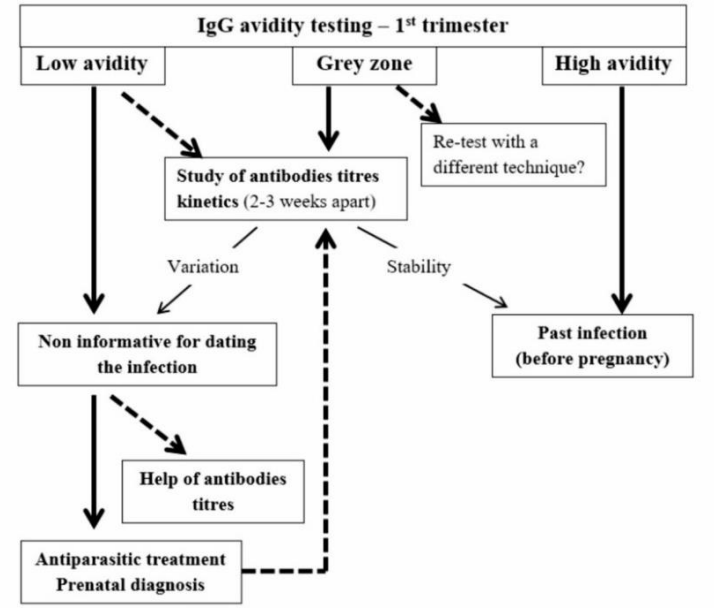

Fig. 3. Interpretation of IgG avidity testing and management in 1st trimester (Adapted from *Garnaud*, 2020)

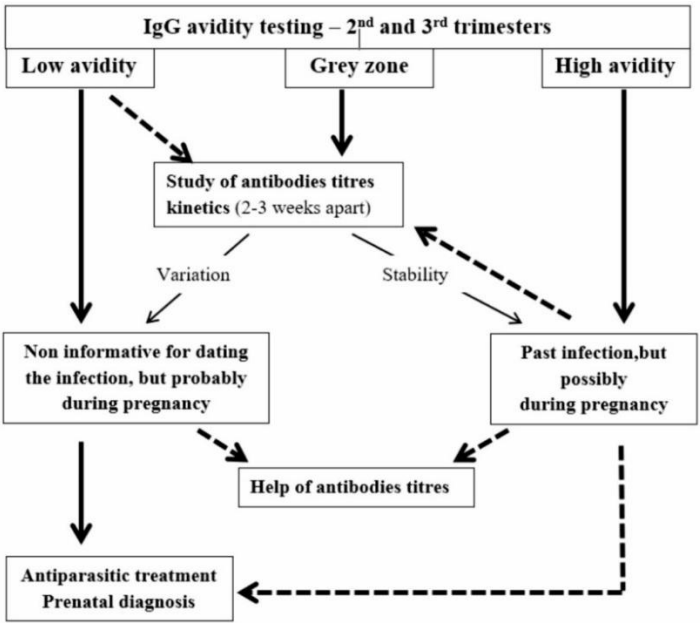

Fig. 4. Interpretation of IgG avidity testing and management in 2nd and 3rd trimesters (Adapted from *Garnaud*, 2020)

CONCLUSIONS

We present the particularities of prenatal diagnosis of a high-risk pregnancy for achondroplasia and the utility of IgG avidity test in 1st trimester of gestation for discrimination between a recently acquired infection and an old infection with *Toxoplasma gondii*.

CONFLICT OF INTERESTS AND FUNDING

The authors declare that there is no conflict of interest regarding this scientific research.

SURGICAL COMORBIDITIES - A HIGH MEDICAL AND FINANCIAL BURDEN FOR HEMOPHILIA CARE (Abstract): Comorbidity in hemophilia, a pathology non-related to the primary disease, is a relatively new chapter, catching interest along with the revolutionary improvement of the outcomes of this coagulopathy. **Aim:** As prophylactic replacement therapy has been only recently introduced in our country, we aimed at assessing the frequency and the medical and financial impact of the surgical life-saving interventions of some challenging comorbidities of hemophilia. **Material and methods:** In the frame of a retrospective observational PRO (Patient Reported Outcomes) model survey conducted on 122 persons with severe congenital coagulopathies in the period of 2019-2020, we focused our attention on surgical comorbidities compared with surgical secondary morbidity. **Results:** There were performed 17 surgical interventions on 16 patients, 35.95% of them being for comorbidities. The comparative analysis of the two cohorts of patients, with comorbidities versus secondary morbidity, revealed some significant discrepancies: heterogeneity of the pathologic conditions claiming surgery and the modality of its performance, emergency or elective decision. There were registered also some similarities: age of patients and quality of outcomes. What concerns the financial impact, the medical direct costs were also similar. **Conclusions:** Surgical comorbidities are a high medical and economic burden for hemophilia care, claiming a comprehensive analysis of their approach in order to prospectively find out the best cost-effective and cost-efficient solution on country level for these unexpected, unpredictable diseases. **Keywords:** HEMOPHILIA, COMORBIDITY, SURGERY, COSTS OF INVASIVE INTERVENTIONS.

Comorbidities, as non-interrelated simultaneous diseases are a constantly increasing preoccupation in healthcare (1). It is estimated that >75% of healthcare expendi-

ture is spent on persons with multiple comorbidities, and that the average expenditure/person with comorbidities is roughly five times greater compared with individuals lacking a chronic disorder (2, 3). In the last decade along with the continuous improvement of treatment and of life expectancy of persons with hemophilia (PwH), they have spread also in the field of this rare, lifelong, hereditary coagulopathy (4, 5, 6). They are mainly age-dependent, as the aging population is most likely to catch a wide range of diseases, with decisive medical, economic and social consequences (7, 8).

As things are improving in the field of hemophilia care in our country, bringing along also demographic changes, it could be of interest to understand comorbidities and multiple morbidities in this disease also in our local conditions; it could be the way to plan the strategy for a predictive, personalized, preventive, participatory cost-effective, and cost-efficient solution of hemophilia care, closing the gap between its treatment between our country and that of other European countries (9, 10).

STUDY DESIGN

In the frame of a retrospective cross-sectional observational PRO (Patient Reported Outcomes) model survey conducted on 122 persons with hemophilia (PwH) and its related von Willebrand disease (vWD), diagnosed and treated in 11 neighboring counties from the Western part of Romania, we focused our attention on surgical comorbidities, justified by the fact that they represent the most challenging chapter for the medical care, involving persons with hereditary coagulopathy facing medical bleeding risky interventions. The study referred to the time interval of 1st January 2019 - 31st December 2020. Additionally, to the answers of PwH to a complex questionnaire, medical data have been obtained from the treating physicians and personal hospital records. All participants expressed their informed consent, and the Institutional Ethics Committee approved its performance.

In this comprehensive survey, we aimed at obtaining an insight into the group of comorbidities of PWH, in order to assess, comparatively with secondary morbidities, the frequency, clinical profile, and therapeutic solution of the surgical disease occurring concomitantly with hemophilia/von Willebrand disease, and to evaluate their medical outcomes and financial impact.

MATERIAL AND METHODS

In this survey, we focused our attention on surgical comorbidities, as they generate challenging situations of invasive interventions in the condition of a patient with risky hypo coagulopathy. Out of our 122 PwH and vWD we included in this study two cohorts of patients; 5 cases, presented in emergency, for surgical comorbidity and 11 with elective surgeries performed for the secondary morbidity aiming correction of disabilities or removal of uncontrolled pain in chronic secondary hemophilic hemarthropathies (tab. I).

For the evaluation of the invasiveness of interventions we considered the most used Sant Agostino classification: any elective or an emergent surgical procedure, requiring general anesthesia/respiratory assistance, in which a major body cavity is penetrated or exposed, a mesenchymal barrier is crossed, a fascial plane is opened or an organ is removed or normal anatomy is operatively altered are the main criteria for the definition of major intervention, the rest of invasive interventions being minor (11).

TABLE I

Classification of PwH with invasive interventions (2019-2020)

Type	Average age (years)	Intervention	Programmed	Emergency
Secondary morbidity	38.63±13.26	-total hip arthroplasty	3	-
		-knee arthroplasty	4	-
		-knee arthroscopy and bone biopsy	1	-
		-giant pseudotumor resection and amputation of the inferior third of the leg	1	-
		-cerebral hematoma evacuation	-	2
Comorbidity	36.52±24.17	-open tibial fracture with implantation of osteosynthesis material (case 1)	-	1
		-bilateral coxal-femoral fracture + arthroplasty + femoral neck cerclage (case 2)	-	2
		-testicular abscess evacuation (case 3)	-	1
		-cheilognatopalatoschisis plasty (case 4)	-	1
		-open heart surgery - aortic valve implantation + ascending aorta reduction plasty (case 5)	-	1
Total	37.97±16.55		9	8

SHA - severe hemophilia A, MHA - moderate hemophilia A,
SHB - severe hemophilia B, vWD - von Willebrand Disease

In accordance with the WFH guidelines, we assured a tailored, personalized replacement therapy, under the monitoring of the trough level of the coagulation factor concentrates (CFC) (12). In one child, who developed high titer inhibitors the treatment was assured with bypassing agents (BPAs - rFVIIa, aPCC). A special attention was given to the patient with aortic valve replacement, dilatation of ascending aorta, and cardiac insufficiency, whose intervention with cardio-pulmonary bypass and extracorporeal circulation needed a challenging mixture of contradictory medicines: CFC and unfractionated (UFH) followed by fractioned heparin (FH), antifibrinolytics (EAC), and antiaggregants (aspirin); he required a tough control of hemostasis with additionally thromboelastogram (TEG) and Thrombin Generation Assay (TGA). For the evaluation of the outcomes, we used the definitions proposed in the WFH Guidelines for Hemophilia Care (12). In the economic evaluation, we considered for direct medical costs: specific medicines (CFC and BPA), biological and imaging assessments for diagnosis and monitoring and hospital admission. All data regarding the real costs were sourced from the administrative departments of the treating clinics and from publicly available data, expressing them in national currency (RON) exchanged in EUR at the present rate; when necessary, in order to avoid some bias, we also calculated the costs/person/hospital day and body weight (BW) adjusted costs. Only the costs spent in the period of hospitalization have been considered, not calculating the consumption of CFC in the ambulatory treatment and during rehabilitation, physical therapy. We have not included the indirect costs for transport, sick leave, and loss of productivity.

Statistical analysis was performed using *Microsoft Office Excel* 2013 and *SPSS 14.0* for Windows Evaluation Version, calculating the average and standard deviation with significance at $p<0.05$ and a correlation coefficient significant when $r > 0.4$.

RESULTS

Our study group consisted of 122 patients, 114 (93.4%) with severe and 8 (6.56%) moderates with severe phenotype, 92 (75.4%) with hemophilia A (HA), 16 (13.1%) with hemophilia B (HB) and 14 (11.48%) with von Willebrand disease (vWD). We have assessed comorbidities in 79.51% *vs.* 25.64 % of cases with an age higher or lower than 23 years, respectively, with a Cumulative Illness Rating Scale (CIRS) of 373 *vs.* 64 in these groups of patients (13).

In the period of 2019-2020 there have been registered 17 surgical interventions (tab. II), 8.5/year, less than in previous years, considering that in 2020, dominated by the COVID-19 pandemic, only emergencies were accepted; 6 (35.29%) of them were dedicated to comorbidities; it is to mention that two major interventions were performed on the same patient with a post-traumatic orthopedic event. Their average age was 38.63 *vs.* 36.52 years in the secondary morbidity *vs.* comorbidity group (p=0.97), respectively, without age-dependence of both cohorts; surgical comorbidities (r=0.006) like secondary morbidities (r=0.06) were non-age related, in contrast with the global comorbidities (r=0.69), strongly dependent on the age. All were with severe HA, except one with severe type III vWD; one of the patients developed anti-FVIII inhibitors. Comorbidities had a rather heterogeneous profile of surgery: orthopedics-3, genitourinary-1, maxillofacial-1 and cardiovascular-1, in comparison with that of secondary morbidity dominated by orthopedic interventions (p=0.01). They all were performed as emergency or condition-assumed emergency (cardiac insufficiency, and cheilognatopalatoschisis) interventions (tabs. I, II), *vs.* PwH with secondary morbidity, all with elective programmed intervention (p=0.07). All interventions, in both cohorts of patients, were major procedures. Regarding the hemostatic efficiency in 14 cases the outcomes were excellent and in 3 cases were good, similarly distributed in the two cohorts.

Besides the important medical and social burden of these invasive interventions for the patients and caregivers, supplementary financial tasks for the society were also considered. The costs, dependent mostly (> 90%) on the replacement therapy, were very high in all the 3 scenarios:

- factor VIII/IX replacement in major surgery in PwH without inhibitors,
- switch to BPAs therapy in a patient developing a high titer anti-FVIII inhibitors and
- a challenging mixture of CFC with anticoagulants, antifibrinolytics, antiaggregant; considering the diverse BMI we calculated the real costs and also, the BW adjusted costs; beside the total costs during hospital admittance, we also expressed the costs/person/day.

The distribution of the annual direct costs/patient are presented in the third table. The daily direct medical costs in the cohort of patients with secondary morbidity without inhibitors, who underwent surgical interventions, were 1,873.8 ±725.15 Euros *vs.* cases with surgical comorbidity (1,687.76 ± 927.45 Euros), are not significantly different (p=0.35).

TABLE II

The etiopathogenic background of invasive interventions in PwH (2019-2020)

Type of intervention		Type of disease	Age (years)	Secondary morbidity	Comorbidity
Orthopedics	-total hip arthroplasty	SHA	42/52/29	3	-
	-knee arthroplasty	SHA vWD type3	46/39/37 50	3 1	-
	-knee joint arthroscopy and bone biopsy	SHB	44	1	-
	-giant pseudotumor resection and lower third leg amputation	MHA	36	1	-
	-post traumas open tibial fracture with implantation of osteosynthesis material	SHA	34	-	1
	-post-trauma coxofemoral fracture + arthroplasty neck cerclage	SHA	51	-	2
Genito-urinary surgery	-testicular abscess evacuation	vWD type 2	32	-	1
Oral and maxillofacial surgery	-cheilognatopalatoschisis plasty	SHA+ inhibitors	0.6	-	1
Cardiovascular surgery	-replacement of the aortic valve, ascending aorta reduction	SHA	65	-	1
Neurosurgery	-cerebral hematoma evacuation	MHA	4/46	2	-
Total				**11**	**6**

TABLE III

Direct costs (Euro) of surgical interventions in PwH, during the hospital stay

Case Number	1, 2, 3	4	5
Age (years)	42.5±12	0.6	65.00
Hospitalization costs	3,850.10 ±1,202.08	4,300.00	1,300.00
Costs of specific treatment (CFC / BPA)	55,051.54± 16,620.65	31,923.51 *266,561.40(BW adjusted)*	36,339.98
Percentage of total costs	92.67	86.90 *98.20 (BW adjusted)*	95.27
Costs for investigations	567.8 ±107.10	510.30	503.10
Total costs	59,404.64±15,418.57	36,733.80 *271,371.70 (BW adjusted)*	38,143.10
Hospital days	38.5±14.23	43.00	13.00
Costs / patient / day	1,687.76±927.45	854.30 *6,199.10(BW adjusted)*	2,934.00

DISCUSSION

The term "comorbidity" indicates any medical condition existing simultaneously with, but independent of a patient's primary disease, being mostly age dependent. In fact, the age-dependence of "secondary morbidity" varies with the quality of hemophilia treatment. In Sweden, before 1970, about 37% of PwH had the first joint replacement by the age of 30, reduced to 21% and 0% in the period of 1970-1979 and after 1980, respectively (14). The lack of such age-dependence in our survey is due to the fact that prophylactic replacement has been actually introduced in our country only recently (2016/2017), many of the adults and young adults suffering from important secondary morbidity; therefore, the average age in the two groups of PwH, with secondary- and comorbidity were similar, 38.63 *vs.* 36.52 years, respectively.

Due to the revolutionary advances of hemophilia treatment, the life expectancy and quality of life succeeded to get comparable with those of the non-hemophilic male population, concomitantly decreasing the secondary morbidity and increasing the frequency of comorbidity (14, 15). Middle-aged or elderly PwH had in 78% of cases at least one comorbidity and 15% of them at least 3 or more comorbid conditions (16, 17). In fact, they can be considered the downside of increased life-expectancy. This new landscape brings to the general attention the problem of aging hemophiliacs: firstly, for development of the comprehensive multidisciplinary medical assistance, and secondly, for an appropriate evaluation of the supplementary unexpected costs necessary to construct the best affordable and the most efficient strategy of their economic management (16, 17). Not to be neglected is the need for the establishment of appropriate treatment centers with a turn-around time activity of 24 hours/day and 7 days/week, with access to the proper medication, to the complex specific exploration and to a well-trained surgery team, facing a non-programmed major life-or limb-saving intervention.

Comorbidities in hemophilia can be very provocative. On one hand, the associated morbid condition itself or its treatment can interfere with hemostasis, generating an additional bleeding risk; on the other hand, hemophilia will impose supplementary attention in therapy or hemostasis monitoring. Our reported cases are illustrating these problems. The infant with cheilognatopalatoschisis, with recommended timely performance of surgical correction required a replacement with its missing CFC VIII; but, during its postoperative monitoring, there was an obvious unsatisfactory hemostatic response, with a low recovery of FVIII, justifying the laboratory reassessment, which revealed high titer FVIII inhibitors, compelling the switch to another life-saving therapy with BPAs. The other reported case of an adult with a life-threatening heart-disease, needing an emergent surgical solution created the most challenging situation : open-heart surgery with cardiopulmonary bypass, and extracorporeal circulation, having in his treatment protocol besides the CFC replacement, also anticoagulants, antifibrinolytics, and antiaggregants; daily coagulometric, TEG, and TGA assays were mandatory in order to balance between these contradictory agents for finding a safe hemosta-tic control.

Another aspect, which is worth to be mentioned is the non-evident, concealed,

sometimes non-investigated relationship between comorbidities and secondary morbidity in hemophilia. That issue justified our attention in the case of evident trauma-related double femoral neck fractures (tab. I). The highly osteoporotic image of the bones was striking, impacting also coxofemoral joints. The only therapeutical solution was the arthroplasty with neck cerclage. It raised the following questions: was it indeed a non-hemophilia-related fracture or was it a consequence of the hemophilia-related osteoporosis? To answer these questions, there are now many pre-and clinical studies, all agreeing that the prevalence of fracture is significantly higher in PwH than in the normal population. Besides low physical activity, low vitamin D, low body mass index, hypogonadism, tobacco, and alcohol use are discussed; additionally, the multifactorial substrate of this condition has been also proved, FVIII and vWF playing a role in osteoclastogenesis. Large studies revealed osteopenia in 43.5% and osteoporosis in 25.8% of PwH, increasing the fracture rate to 24.0%/1,000 PwH/year *vs.* 9.6%/1,000/ control group patient/year, with a yearly increase of 1-3%/year of its prevalence (18).

Concerning the costs of the surgical comorbidities, our short-term survey revealed its magnitude. Concordantly with the international data, the proportion of expenses dedicated to the specific CFC or BPA were 92.67-98.20%, being lower in the situation of long-term hospitalization (16, 17, 18, 19, 20). The occurrence of inhibitors is increasing the expenses by 3-5 times (20). In our infant patient, who developed high titer inhibitors, there was a significant rise in costs, but its dimension is much clearer if we calculate for comparison the BW-adjusted value of costs. The deleterious effect of the association of both types of morbidities has been once more revealed: secondary and comorbidity. Therefore, we have to accept that the avoidance of secondary morbidity, treatment-dependent, is the most efficient economic attitude, preserving at the same time a better quality of life. Hemophilia itself is an already costly disease. If we take into consideration also our affordability in the frame of our national hemophilia program, the average annual budget/PwH being about 30,000 Euros, the costs for such unexpected and unpredictable comorbidities are significantly increasing the financial burden of the incurred expenses.

As limits of our study, we have to mention the short-term horizon of our review, also including the period of the bad COVID-19 pandemic, impacting all the medical care in the country; additionally, the small number of the patients with this rare disorder and the low rate of surgical events, lead to difficult statistical evaluations. Despite not having included the important post-hospital direct and indirect costs, connected with this comorbidity, we could demonstrate the high economic burden of a such morbidity. It is also to highlight the risk of over-estimation of the costs of hemophilia care on the country level, as in our center is functioning a multi-institutional comprehensive hemophilia care with PwH addressed from all over the country.

CONCLUSIONS

This critical and provocative issue of surgical comorbidities in hemophilia requires a more extended approach in time

and space in our real life. It is suggesting the imperative lifesaving need to organize a network of comprehensive care centers, for finding economic arguments for immediate access to the right medical team, to the right medication and dosage, individualized for the right patient, according to complex hemostatic monitoring, basis for foreseeing a prospective predictive attitude for a cost-effective and cost-efficient solution to cover all their needs.

NEWS

ISOLATED MYOCARDIAL BRIDGING: A POTENTIAL CAUSE OF SUDDEN CARDIAC DEATH

Myocardial bridging (MB) is a congenital coronary anomaly in which a segment of coronary vessels is embedded into myocardium tissue. In sudden cardiac death (SCD) autopsy series, left anterior descending coronary (LAD), particularly the proximal segment, is the most common affected vessel in MB. However, several studies report involvement of multiple segments of MB in the same or different coronaries. As the majority of coronary blood flow occurs only during diastolic phase, delayed relaxation in MB during diastolic phase is responsible for coronary blood flow reduction. This pathophysiology plays an important role in the lethal consequences of this anomaly. The coronary obstruction of MB has been classified into either benign or pathologic according to their location, intra-myocardial length, and intramyocardial depth. Pathologic MB is considered if the bridging segment is 20–30 mm long and 2-3 mm deep. In some cases, pathologic MB may cause ischemia, infarction, malignant ventricular arrhythmias, and eventually SCD. However, there was a case report in which the evidence of ischemia and infarction were found despite benign MB affirming that the clinical consequences do not depend on the degree of coronary blood flow reduction. Although MB has been recognized for decades, the clinical significance of MB as a potential cause of SCD remains a subject of debate. According to previous studies, the probability of MB in Caucasian population as the only potential cause of SCD was quite low. The authors try to review the potential relation between MB and conventional risk factors and identify cardiovascular events for establishing the understanding of the clinical implications of MB **(**Vutthikraivit W, Rattanawong P, Prapaipan Putthapiban P, *et al.* Isolated Myocardial Bridging: A Potential Cause Of Sudden Cardiac Death. *Rom J Leg Med* 2020, 28: 133-136).

EFFICIENCY OF USING VISUALIZED TREATMENT OBJECTIVES IN ORTHODONTICS

EFFICIENCY OF USING VISUALIZED TREATMENT OBJECTIVES IN ORTHODONTICS (Abstract): Lateral skull radiographs are used to perform cephalometric measurements and to evaluate the skeletal component of the orthodontic anomalies. It is difficult for the patients to imagine the expected outcome of their orthodontic treatments. so visual treatment objectives (VTO) can be a significant motivating factor. It can be used to illustrate the expected growth. the outcome of orthognathic surgery and the amount of teeth movements. This study was **aimed** to evaluate the accuracy of the visual treatment objectives through analysis of predicted and actual treatment outcomes. The second objective was the comparison of the initial cephalometric measurements with the final ones and the visualized treatment objectives prediction accuracy. **Material and methods:** Using the AudaxCeph cephalometric program and Roth-Jarabak analysis, lateral skull radiographs of 27 patients were analyzed. Visual treatment objectives were assessed by modification of the dental parameters as well as of the skeletal bases where indicated. **Results:** Lateral skull radiographs taken after the orthodontic treatment were used to evaluate the final cephalometric measurements. Statistical comparison of the dental and skeletal measurements of the final radiographs and the visual treatment objectives did not show statistically significant differences of the most important parameters. However, the following measurements were significantly different when compared with the visual treatment objectives Ar-Go-N angle (degrees), Go-Ar distance (mm) and S-Ar / Ar-Go ratio. **Conclusions**: Using the VTO, the expected orthodontic outcome can be well estimated, and it can be considered an effective tool for planning.
Keywords: ORTHODONTICS, CEPHALOMETRY, TREATMENT OUTCOME, RETROSPECTIVE STUDIES.

A visual plan can be very helpful in predicting patient growth and the expected effects of treatment, as well as determining the goals that need to be achieved for the patient. The use of Visual Treatment Objectives (VTO) also allows alternative treatment plans to be developed. Using VTO the advantageous aspects of growth should be exploited, interpreting the indicators from the cephalometric radiograph's

evaluation. If possible, the undesirable effects of growth should be also reduced during treatment. Progress can be continuously monitored during treatment, with the help of the dental VTO. In the 1980s, these visual goals were still manually drawn on tracing paper, but with the proliferation of digital X-rays and the advent of numerous cephalometric programs, this has now been completely pushed into the background. The time of preparation of the VTO depends entirely on the case and can be used as a supplement to traditional cephalometric analyzes (1, 2, 3).

Richard McLaughlin and John Bennett published a study in 1999 entitled "The Dental VTO: An Analysis of Orthodontic Movement" to provide simplified and organized information for diagnosis, design, and to resolve the issue of non-extraction / extraction, using the VTO. The study includes two case studies of patients with skeletal second-class anomalies (4).

Subsequent research has used VTO to design cases of orthognathic surgery and to accurately depict surgeries, with a strong emphasis on predicting soft tissue changes. For example, in the study of Pektas *et al.* (5), the accuracy of Dolphin Imaging System software prediction was examined at the soft tissue level, before surgery and then one year after surgery. In the study, the treatment approaches also included surgeries on both the maxilla and the mandible (5).

Robert J. Peterman *et al*. in a similar study. focused on soft tissue analysis. Pre- and post-treatment lateral skull radiographs were superimposed to determine the skeletal movements actually achieved during orthognathic surgery. This information was used to simulate soft tissue changes in patient profile in preoperative photographs. The accuracy of the VTO was further examined by comparing the projected images with photographs taken after the end of treatment (6).

This study was aimed to evaluate the accuracy of the visual treatment objectives through analysis of predicted and actual treatment outcomes. The second objective was the comparison of the measurements in order to determine the visualized treatment objectives prediction accuracy.

MATERIAL AND METHODS

The survey included the lateral skull radiographs of 27 patients (18 women and 9 men) aged between 9 and 30 years, who required orthodontic treatment. The number of growing patients was 15, while the number of young adults with completed ossification was 12. Patients visited the *Natural Smile Dental Clinic* for orthodontic treatment. Individualized treatment plans were established for each case considering clinical examination, study cast analysis, profile photos, age, anatomical boundaries and patient's intent. All patients signed an informed consent to participate in this study.

Photographic documentation was prepared for each patient. It included extraoral and intraoral photographs using a Canon 500 camera and 100 macro lenses. illuminated by a circular flash The intraoral images were taken from frontal, lateral, and occlusal views. The extraoral images were taken with a blue background, from the frontal and lateral view, both in rest and smile.

Panoramic and cephalometric radiographs (fig. 1) were taken for each patient before and after treatment. These digital X-rays were taken with a Pax Flex 3D +, Vatech X-ray machine with an exposure time of 12.9 seconds, 80 kVp and 9.0 mA. The EasyDent dental imaging software and

the AudaxCeph orthodontic cephalometry program were used in the study.

Fig. 1. Lateral cephalometric radiograph

During the survey, individual folders were created for all 27 patients, containing personal data of the patients, with lateral cephalometric radiographs and profile photos before and after treatment. Because not all types of analysis contain all the information needed to establish a VTO, in the present study X-rays were assessed by Roth-Jarabak analysis.

The given analysis type contains the following data:

- Geometry (reference points and planes) and measurements;
- Correlation of measurements with standard values;
- Predefined ‘superimposition’;
- Component sequences for sequential redrawing;
- Position and content of additional elements (measuring boxes, harmonic box, diagram and measuring table);
- Export template and print results.

The software automatically assigns the reference measurement points and planes (fig. 2).

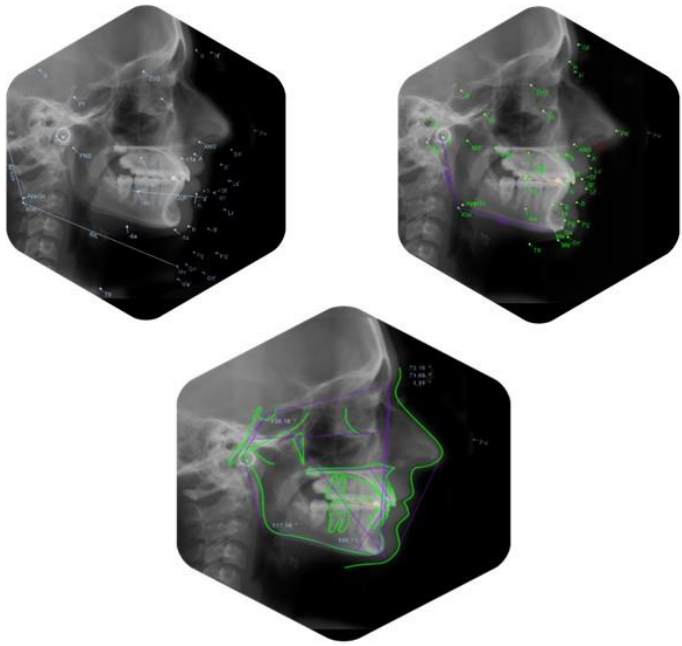

Fig. 2. Jarabak analysis steps

The precise positioning and adjustment of each cephalometric point to the corresponding anatomy formula is done manually. The X-ray image is calibrated by using the gradation visible on the cephalostat. During image calibration, the length and distance of objects are determined based on the known length of each element. The measurement process ends with the creation and editing of the outlines of the teeth, hard and soft tissues. Finally, by clicking the save option, the program provides the obtained values from the given patient (fig. 3).

Fig. 3. Lateral cephalometric radiograph imaging analysis summary (Print Out)

Based on the established treatment plans preparation of the visual treatment objectives (VTO) was done. The VTO permitted the following features:

- to move the items to the desired position;

- to calculate the expected growth;
- to create / present a view state at the request of the patient;
- to save the predicted changes.

With each interactive movement of the teeth, a delta box appears showing the relative distance and rotation. By opening this dialog box, can be also entered the X and Y distances manually. In patients with active growth after enrollment (5 children), the rate of growth was also assessed (approximately 1-2 mm / year) and then the physical advancement of the jawbones was plotted in the VTO.

The lateral view photograph was superimposed to the lateral skull radiograph. Based on the VTO, the soft tissue contour of the profile was automatically modified by the software, creating a new image showing the expected outcome of the treatment.

NAPg°	177.37	6.19

Following the dental and skeletal movements performed in this way, the software creates a table of estimated values for the changes made with the VTO, and the expected dental and skeletal changes provided by the treatment plan.

The Roth-Jarabak analysis was performed on the final lateral skull radiographs taken when the orthodontic treatment was completed.

The results of the obtained measurements of the initial and final analysis and the VTO estimation were entered into an *Excel* database manager. Statistical analysis was performed *t-Student paired test* was performed ($p \leq 0.05$) by using Graph Pad

.

RESULTS

Initial dental and skeletal mean values are shown in first table.

Data obtained from the VTO were compared with the final lateral skull radiographs dental and skeletal measurements.

The results are shown in tables II (dental parameters) and III (skeletal parameters).

DISCUSSION

The aim of the present retrospective study was to assess the effectiveness of the VTO. To demonstrate the effectiveness of the program, the estimated values of the visual treatment objectives should not differ significantly from the result and the projected changes should be as close as possible to the patient's final condition.

Statistical figures showed that there was a significant difference in the following three of the seventeen skeletal measurements:

- Ar-Go-N° (articular-gonion-nasion / degree)
- Go-Ar mm (gonion-articular / millimeter)
- S-Ar/ Ar- Go % (sella-articular/ articular-gonion / percent)

These measurements provide important information about the ascending ramus of the mandible. namely its length and degree of angulation. As demonstrated, the VTO prediction of the development and growth of the ramus of the mandible was less accurate than the other parameters.

Only one parameter was found to have a relevant difference, namely Ls / E-line mm (labralis superior to E-line in millimeter). The VTO estimation of the position of the upper lip in millimeters relative to the aesthetic line in the sagittal plane was significally different compared to the final result. This can be related to the protrusion of the upper incisors, as the key to achieving facial balance and harmony is not necessarily the placement of the bony tissues, but rather the position of the maxillary and mandibular teeth that determine the position of the upper and lower lips.

VTO-related studies in the literature have found that computer-generated predictions generally underestimated the nasal apex, under the nose, and A-point soft tissue projection, while they were overestimated for the upper lip (5). In general, predictive errors were smaller in the sagittal plane than in the vertical plane, similar to our results.

Peterman *et al.* found that for most measurement points within ± 2 mm, the software VTO estimate was accurate and the lower lip predictions were the most inaccurate (6).

Comparing the results of the present study with the data in the literature, very similar conclusions can be drawn. However, it should not be overlooked that the present study does not include any surgical cases and is not based on the prediction of soft tissue changes, but mostly on hard tissue measurements (angular values, size of bony anatomical formulas) and accuracy is not by analyzing the differences expressed in millimeters, using statistical procedures. The difference between the expected and the obtained treatment result reflects the effectiveness of the treatment. but in certain treatment procedures. without the patient's consent, the orthodontist is forced to submit the case to a compromise solution, making it impossible to achieve the ideal treatment plan. The goal of visual treatment as a motivational aid can be of great help in preventing these barriers, as it is a much more understandable way for patients to explain the most ideal treatment plans depicted with VTO. In addition to the simplicity, accuracy, and many other benefits of digital design, it should be borne in mind that the presentation of these predictions must be done very carefully and precisely to eliminate unrealistic expectations of patients.

CONCLUSIONS

The dental VTO is a great adjunct to the analysis of lateral cephalometric radiographs determining a diagnosis and treatment plan, but it alone cannot provide a complete picture of the situation.

The orthodontist performing the study can make excellent use of the VTO in communicating with patients in the form of an illustrative presentation as a motivational tool.

A projected graphical representation can provide adequate explanation to patients about the proposed treatment, facilitating its understanding and acceptance and an adequate estimate of the rate of growth for growing patients.

The ascending ramus of the mandible and the position of the upper lip were the least accurate in estimating the VTO, but there was no significant difference in the more important measurements, so its precision is not maximal, but its efficiency is satisfactory.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

Professor Dr. Dumitru Bagdasar is considered to be the founder of Romanian school of neurosurgery. He was born in 1893 in Roșiești, Vaslui, România, in an Armenian countryside family, being the oldest brother. Passionate about knowledge and science, he got the attention of his professor from the beginning of the primary school in Idricii de Sus. He followed his high-school studies in Barlad, and in 1913 he applies for the Medical School in Bucharest. There were many times in his life when because of the lack of material resources, he faces difficulties in carrying on with his medical school. That's why at the end of his 3rd year he enrolled to the Medico-Military Institute trying to get some financial support (1). Quickly, he was sent to give aid to the military troops during the Second World War. Because of the harsh condition on the military front, he got sick of typhus and went through hardships.

After finishing his primary studies in highshool in Barlad, he studied medicine in Bucharest (1913-1919). His postgraduation thesis was published in 1922, entitled "Contributions to the study of postencephalitic parkinsonian syndrome".

Between 1922 and 1926 under the supervision of Dr. Gheorghe Marinescu and Dr. Ion Noica, he specializes in neurology. Under his guidance he published a series of manuscripts about Friedreich Maladie, mediastinal symphatic syndrome, Parkinson's Syndrome, etc. In 1927 Dr. Bagdasar was awarded with a Rockefeller grant and had the possibility to move to Boston, where under the guidance of Professor Dr. Harvey Cushing completed a volunteering-assistance program in neurosurgery.

His neurosurgery activity could be divided in 4 parts: in USA, at the Hospital in Jimbolia (27), Mental and Nervous Disease Hospital in Cernauti (149) and at the Central Hospital for Mental and Nervous Diseases (60) between 1930-1934.

His training in neurosurgery (1927-1929) is performed in Boston, USA, under the supervision of Harvey Cushing. (2). Together with Percival Bailey he published two papers "Treatment of cerebral goma" and "Intracranian cordoblastoma". In his first publication, Bagdasar highlighted that the incidence of intracranial gomas is low, and the surgical treatment is essential since 7 out of 8 had better results of medication treatment following the surgical procedures. His coming to USA was accompanied by his wife, owner of Fulbright grant, and who specialized in social medicine.

Fig. 1. The picture of young Dr. Dumitru Bagdasar

Starting with 1929, Bagdasar and his wife moved back to Romania and started practicing medicine in Jimbolia Hospital (Timis County). At this medical center there were performed the first 27 neurosurgical interventions in Romania, namely 15 ventricular punctures, 9 frontal-parietal approaches, two sub temporal decompressions, a cerebellar decompression, and other 18 procedures outside of the central nervous system.

In 1931, it was organized the first edition of the International Congress of Neurology in Bern, Switzerland whose chairman of the congress was the American neurologist, Bernard Sachs. At this time Cushing presented his memorable study of 2023 cerebral tumors and during the presentation Bagdasar was part of the audience. At the Gala Dinner event organized at Hotel Bellevue, Bagdasar was invited to stay at the left side of Cushing as a sign of dignity and friendship that was shared between them, near Thierry de Martel (France) and his second American mentor Percival Bailey with whom he published his articles in USA. His relationship with Cushing remained stable over time.

In 1932, Bagdasar and his wife Florica Bagdasar moved to Cernauti, where for one year he performed 28 surgical interventions namely 21 surgeries for intracranial lesions and 7 vertebral lesions. All of these surgeries were performed under local anesthesia with Novocain. Some of the cases were presented at the Neurological and Psychiatry Congress in Bucharest, September 1932 under the title "56 Surgical Interventions for Epilepsy. Critical Considerations". At Cernauti Hospital he also performs few neck dissections for peripheral nervous system, "but without the interest to delve seriously in comprehending the peripheral nervous system, since this such a surgery pertains in parts to the general surgery (…)".

In 1933, he performed 31 surgical interventions including laminectomies [2], peripheral nerve trauma surgery [1], cranial decompressions [4], spinal cord sections [6], osteoma (excision) [1], cerebral tumors (excision, exploratory look) [5], medullar tumors (excision) [2], cerebellar tumors (excision) [3], Dandy's operation (neurotomy of 5th nerve) [4], ventriculography [1] and abscess drainages [2].

Among the publication of that period is remarkable the one about the examination of ventricles and cysts gliomas. The authors pioneered a device called ventriculoscop (which is an endoscope that has 30 cm length and 3 mm diameter) and was brought to life by Wolf House in Berlin.

It is worth to be mentioned that besides

his neurosurgical interventions Dr. Bagdasar also performed surgical interventions at the Military Hospital which was supervised at that time by Professor Dr. Mihail Butoianu.

At the end of 1934, it is organized for the first time in Romania the first admission examination for a neurosurgeon place at the Central Hospital for Mental and Nervous Diseases. At that time on the examinations lists there were Dr. Bagdasar, Dr. Moruzi, Dr. Vasiliu. After 3 days of examinations Moruzi and Bagdasar were both on the first positions, however, taking in consideration the years of surgical experience the evaluation commission (which included: Prof. Butoianu, Prof. A. Jianu, and last but not least Prof. L. Balif) decided that Bagdasar should be Chief of Neurosurgery in Bucharest (3).

From 1929 to 1934, he performed over 200 surgical interventions on neurosurgical pathologies (4). Starting from 1935, dr. Dumitru Bagdasar started his activity in a single hospital, the Central Hospital for Mental and Nervous Diseases, in Bucharest as the attending primary neurosurgeon, having under his supervision 10 beds for hospitalization of neurosurgical patients (5). He succeeded in establishing the first independent Neurosurgical Department in Bucharest Central Hospital of Nervous Diseases - the second at a national scale, after Socola Psychiatry Hospital in Iași. Doctor Maria Niculescu, who operated with Bagdasar for a period of 7 years mentioned about the operative room conditions that "*sick patients were screaming, kept behind the bars, in this sinister atmosphere, the beautiful operations were performed on a wooden table, improvised, (...) instruments made according to Bagdasar's instructions, thus following Cushing's example, but without comparable material resources".*

In a filmed interview, Sofia Ionescu, the first female to be neurosurgeon, said that her entire future was marked by professor Bagdasar. She remembered that once Professor D. Bagdasar was unable to operate due to a wound on one of his fingers and he let her to perform her first surgery, saving the life of an 8-year-old comatose boy with an extradural intracranial hematoma. Professor Bagdasar remarkable praised her and required to stay with him during her training (6).

At the Emergency Hospital in Bucharest, ruled at that time by Prof. Iacobovici, Dr. Bagdasar worked day and night diligently with an impeccable technique and operative skill. Dr. Bagdasar worked with his own staff and always brought his own instruments with selflessness for science and for the sick.

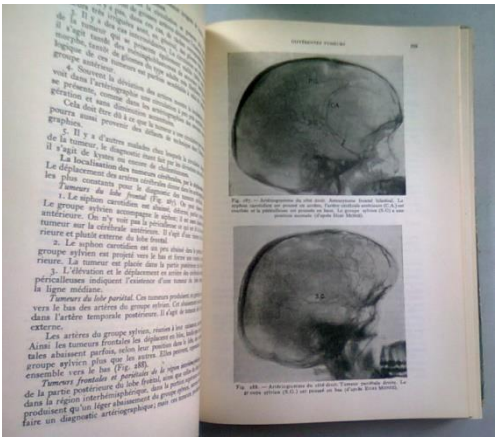

Fig. 1. First cover of *"Traité de Neurochirurgie",* D. Bagdasar & C. Arseni, Romanian Academy, 1948

During his activity Bagdasar participated to numerous medical congresses about history of medicine (International Medical Congress, in Bucharest, 1932), Neurological, Psychiatric and Endocrinological Congress (Chisinau, 1935) and National Surgi-

cal Congress (Bucharest, 1939). In one of his memories published in 1941, Bagdasar mentioned "besides our sick patients, I received cases from Hungary, Bulgaria and Palestine. Over the last 10 years, I practiced over 1800 surgical interventions on nervous system as follows: 473 ventriculographies in diagnostic scope, 988 big cranio-cerebral interventions, 259 laminectomies and 83 peripheral nerve surgeries". He was the author of over 50 specialty monographies. His most important work *"Traité de Neurochirurgie"* (fig. 2), was published postmortem in 1948, and represented the main study book for over 25 years for Romanian neurosurgery trainees (7).

Alexandra Bellow, the daughter of dr. Bagdasar mentioned in one of her late writings about the political involvement of his father. Dumitru Bagdasar enrolled in the Communist Political Party in 1943, participated in signing the memoir in 1944 according to they support Romania's exit from the Second World War. Dr. Bagdasar was assigned as the chief of Health Governmental Ministry in 1945 in the cabinet of Petru Groza. One of the stories from that time marked the moment when Bagdasar was assigned with a bodyguard and an official ministry car was given to him. He refused the governmental car, looking for riding his own car with the bodyguard. Once, coming back from the hospital he encountered a mass of drunken Russian soldiers who asked him and his staff to get out of the car. He remembered quite ironically that the first one who fled away was the bodyguard. In 1945 doctor Bagdasar was appointed professor.

He contributed to the "Red Aid" Romanian branch, an organization whose role was to support the communist hard workers and prisoners. He pleaded for the rights of the communist people in court as witness. All of this pro-socialist work should be understand looking through the eyes of the person who faced hard and difficult times, who felt poverty and agony at its thin limits. A person like Bagdasar who felt more for the Romanian people than for himself was determined to act for the common wellness of the population.

Dumitru Bagdasar died on 16th of July 1946, after several months of suffering. He was diagnosed with incurable pulmonary cancer at Wien, and he personally gave himself the second diagnostic of cerebral metastasis after the onset of apraxia. He gave up city life for a countryside retreat. On his deathbed, he called his collaborators: Dr. Constantin Arseni, Dr. Ionel Ionescu and Dr. Sofia Ogrezeanu Ionescu who then pronounced his last words: "Do your best to grow this specialty. Be united. Continue what you started at the same pace, with the same passion and, above all, with high morality". He wished Dr. Constantin Arseni to be his successor at the clinic. He also became post-mortem member of the Romanian Academy in 1948.

In conclusion, doctor Dumitru Bagdasar is one of the representative figures of a golden age of Romanian Medical School. Together with other representants of his period he pioneered in the domain of neurosurgery being coined as the father and founder of Romanian neurosurgery. His courage in acting in an unknown domain of medicine is remarkable despite any other obstacles that he encountered. His decision to dedicate his life to the neurosurgery made him an example for the Romanian school. His power for acting towards his goals resides in his deep moral character and values. In addition to his integrity and courage comes up his finest clinical sense of discernment. At the end of his path, he is

remarkable one of the personalities who fulfills his calling and completes his mission. Dumitru Bagdasar made history through his records he held, his innovations, the surgeons he trained and his dedication towards the goal of saving lives.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

CLINICAL MOLECULAR IMAGING FOR ATHEROSCLEROTIC PLAQUE

Atherosclerosis is a well-known disease leading to cardiovascular events, including myocardial infarction and ischemic stroke. These conditions lead to a high mortality rate, which explains the interest in their prevention, early detection, and treatment. Molecular imaging is able to shed light on the basic pathophysiological processes, such as inflammation, which cause the progression and instability of plaque. The most common radiotracers used in clinical practice can detect increased energy metabolism (FDG), macrophage number (somatostatin receptor imaging), the intensity of cell proliferation in the area (labeled choline), and microcalcifications (fluoride imaging). These radiopharmaceuticals, especially FDG and labeled sodium fluoride, can predict cardiovascular events. The limitations of molecular imaging in atherosclerosis include low uptake of highly specific tracers, possible overlap with other diseases of the vessel wall, and specific features of certain tracers' physiological distribution. Authors consider the need for a common protocol for patient preparation, data acquisition, and quantification in the area of atherosclerosis imaging research (Anton Kondakov and Vladimir Lelyuk. Review- Clinical Molecular Imaging for Atherosclerotic Plaque. *J. Imaging* 2021; 7(211): 1-15).

HISTO-ANATOMICAL CHARACTERISTICS OF THREE VARIETIES OF *PERILLA FRUTESCENS* LEAVES

HISTO-ANATOMICAL CHARACTERISTICS OF THREE VARIETIES OF PERILLA FRUTESCENS LEAVES (Abstract): *Perilla frutescens* is a crop species, which belongs to the *Perilla* genus in the Lamiaceae family, and it is widely grown in Asia. *Perilla frutescens* species contain two varieties with a lot of forms, including *Perilla frutescens* var. *crispa* f. *purpurea*, *Perilla frutescens* var. *frutescens* f. *crispidiscolor* and *Perilla frutescens* var. *frutescens* f. *viridis*. Perilla has been studied by many researchers for its chemical composition and pharmacological effects. **Aim:** The description of the microscopic characteristics of the three varieties' leaves to emphasize certain differences that allow the identification of the taxons. **Material and methods:** The investigations consisted of the histoanatomical assessment using optical microscopy and scanning electronic microscopy, of each important structure found in leaves of the three genotypes of the *Perilla frutescens* species, harvested from Vegetable Research and Development Station Buzău in September 2020. **Results:** From the perspective of tissue anatomy, there is no significant difference in leaf structure between the three genotypes of the perilla. A difference is observed in *Perilla frutescens* var. *frutescens* f. *crispidiscolor*, which, in addition to all the structures of *Perilla frutescens* var. *crispa*, also contains a different number of peltate glandular trichomes. **Conclusions:** In the histoanatomical study of the three species of *Perilla frutescens* with the light microscope and the scanning electron microscope, we have obtained anatomical characters that show the similarities and differences between the three species. **Keywords:** *PERILLA FRUTESCENS*, OPTICAL MICROSCOPY, SCANNING ELECTRONIC MICROSCOPY, HISTO-ANATOMY.

Perilla is an annual herbaceous plant that belongs to the Lamiaceae family and is widely distributed especially in China, Japan, Korea, Vietnam, and other regions in Asia (1). In Europe, *Perilla* was brought late and used for its oils, but cultivated in small areas (2). *Perilla* contains four species: one that is cultivated

and most frequently named *Perilla frutescens* and three wild species named *Perilla hirtella*, *Perilla setoyensis*, and *Perilla citriodora* (3, 4). *Perilla frutescens* species was divided by Yu according to leaves color in green and purple (5).

In 2010, Hu classified *Perilla frutescens* species in five varieties: *acuta*, *auriculato-dentata*, *frutescens*, *crispa* and *arguta* (6). Nowadays, there are three varieties: *frutescens*, *crispa*, and *hirtella*, that are accepted by The Plant list (7, 8), while the Integrated Taxonomic Information System accepts only two (var. *crispa* and var. *frutescens*) (9, 10).

Perilla frutescens species includes multiple forms of the two varieties, among which: *Perilla frutescens* var. *crispa* f. *purpurea*, *Perilla frutescens* var. *frutescens* f. *crispidiscolor Perilla frutescens* var. *frutescens* f. *viridis*. These varieties are distinguished by the following morphological characters: *Perilla frutescens* var. *crispa* f. *purpurea* present purple leaves on both sides and ruffled surface, *Perilla frutescens* var. *frutescens* f. *crispidiscolor* presents green leaves on the adaxial side and purple on the abaxial side (10), and *Perilla frutescens* var. *frutescens* f. *viridis* present large green leaves on both sides with many wrinkles (11).

Perilla frutescens has been investigated by many researchers in terms of its chemical composition and pharmacological actions (12). A variety of compounds have been isolated and identified from this plant, including flavonoids, volatile oils, fatty acids, triterpenes, phenolic compounds, and so on. The isolated compounds showed pharmacological actions such as antioxidant, anti-inflammatory, anticancer, antidepressant, antiallergic, etc. (12).

Photonic and electron microscopy investigations by Zhou *et al.*, 2021, indicated the presence of three distinct types of secretory hairs, which the authors classified as peltate, capitate, and digitiform. According to the analyses performed, the authors conclude that the secretion of pelted hairs contains perilla ketone, isoegomaketone, and egomaketone, which are major constituents in the leaves of *Perilla frutescens* (13).

Although many species (*Lavandula sp.*, *Teucrium sp.*, *Ajuga sp.*) belonging to Lamiaceae family have been previously characterized by microscopic means, similar data referring to various taxons of *Perilla* is scarce (14, 15, 16). Therefore, our study aimed to describe the microscopic characteristics of leaves from the three genotypes and to identify if there are differences between them.

MATERIAL AND METHODS

The plant material used in this study for histo-anatomical examination under an optical microscope and scanning electron microscope was represented by the leaves harvested from the three genotypes of the species *Perilla frutescens*, respectively: *Perilla frutescens* var. *crispa* f. *purpurea*, *Perilla frutescens* var. *frutescens* f. *crispidiscolor*, and *Perilla frutescens* var. *frutescens* f. *viridis*.

The leaves were harvested in September 2020 from the crops made at Vegetable Research and Development Station Buzău and preserved in 70% ethyl alcohol. The vegetal material is properly

labeled and preserved in the collection of Plants anatomy and morphology laboratory "Academician Constantin Toma" from Biology Faculty within "Alexandru Ioan Cuza" University of Iaşi, having the value of voucher specimens.

The samples to be analyzed were fragments of the petiole, leaf tongue, and rectangular portions of the leaf tongue, including the median rib. Different sections were made for each sample using a botanical razor, botanical microtome, and two halves of extruded polystyrene (shock marrow replacement).

The obtained sections were exposed to the coloring process with iodine green and red ruthenium, but before, were immersed in sodium hypochlorite solution for 10 minutes, then washed with acetic water. After washing, the sections were stained with iodine green, then washed with 90% ethyl alcohol, then with distilled water, after which they were stained with red ruthenium. Finally, the sections were washed with distilled water and mounted on microscope slides in a drop of water. The sections were examined and photographed under a Celestron 44341 LCD built-in optical microscope. The color photos obtained were digitally processed using the Photos software.

As for the scanning electron microscopy investigations, they were performed using the TESCAN Vega II SBH microscope with a secondary electron surface (biological material is dried with carbon dioxide using the EMS 850 critical point dryer, metallization the samples are made of gold using the EMS 550x metallizer). For TESCAN Vega II SBH scanning electron microscopy investigations of plant material, plant fragments were deposited on aluminum foil coated with double-sided carbon tape. The material was then coated with gold by the metallization process on the EMS 550x Metallizer and placed under a microscope for examination.

The use of this modern method of investigation provided additional information on the conformation of the cuticle, epidermal formations (ordinary epidermal cells; surface trichomes (non-glandular) and secretory (glandular) hairs; stomata; cuticular striae), information that completed the data table on the of the surfaces of vegetative organs investigated.

RESULTS AND DISCUSSION

The leaf structure from a histo-anatomical point of view has no significant dissimilarity between the three genotypes of *Perilla frutescens*.

Petiole

Cross-section throw petiole revealed only one difference between the basis and the top of the leaf blade: the numbers of trichomes that are several on the adaxial side than abaxial one. On all three genotypes, the cross-section is semi-circular modified by two slightly protruding lateral-adaxial wings. The adaxial side of the epidermis has besides regular epidermic cells many trichomes, including uniseriate multicellular surface trichomes and capitate glandular trichomes, that are short.

There is one difference observed on *Perilla frutescens* var. *frutescens* f. *crispidiscolor* that contains besides all structures of *Perilla frutescens* var. *crispa*, also a various number of glandu-

lar peltate trichomes. Making this observation we can suppose that *Perilla frutescens* var. *frutescens* f. *crispidiscolor* have at least theoretically the most quantity of volatile oil (fig. 1).

On the other hand, on the abaxial side we can find the same trichomes, but in a very small number. What we can find on the abaxial side in a large number are the stomata located well above the external level of the epidermis. This condition appears in two situations if the vegetal material is excessively watered, especially if it comes from a greenhouse or represents an ecologic adjustment. Considering that two samples were harvested from the greenhouse (*Perilla frutescens* var. *frutescens* f. *viridis*, *Perilla frutescens* var. *frutescens* f. *crispidiscolor*), and one from the field (*Perilla frutescens* var. *crispa* f. *purpurea*) we can say that this position of stomata represents an adaptation to the Romanian climate and type of soil. Below both epidermic sides are located two-three layers of angular collenchyma, a mechanic tissue that has a purpose in support and guidance of the leaves after the light source.

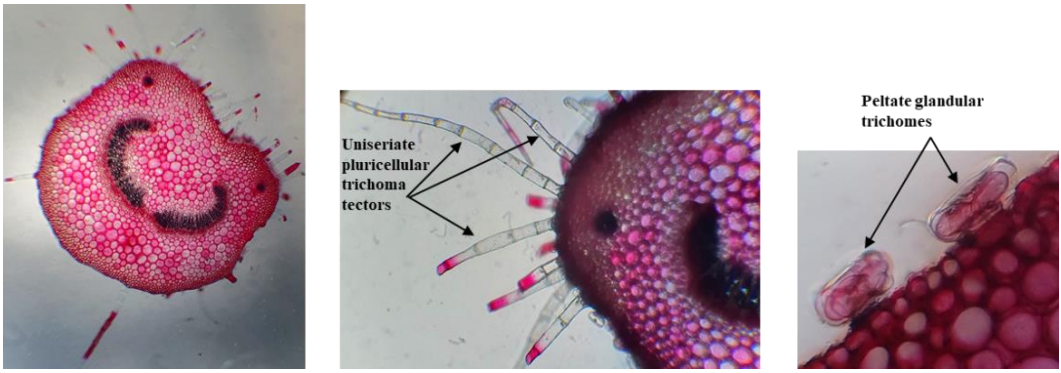

Fig. 1. Petiole of *Perilla frutescens* var. *frutescens* f. *crispidiscolor* - cross section view and detail (x20; x100; x400)

In fundamental parenchyma, there are conducting tissue that is organized in two arches that are oriented with phloem tissue through the abaxial side and with lignified tissue through the adaxial side. The two arches are separated by fundamental parenchyma cells. In patches, near phloem cells, there is a thin slightly sclerified and lignified sheath (fig. 2). On *Perilla frutescens* var. *crispa* forma *purpurea* we couldn't find that sheath (fig. 3). This finding may be a characteristic element of the separation between *Perilla frutescens* var. *crispa* f. *purpurea* and *Perilla frutescens* var. *frutescens* f. *viridis*. The two slightly protruding lateral-adaxial wings have the same structure as fundamental parenchyma as follows conducting tissue with the same orientation, many stomata placed above the outer level of epidermic cells, and from place to place near phloem cells we can find one layered sheath with elements of sclerenchyma.

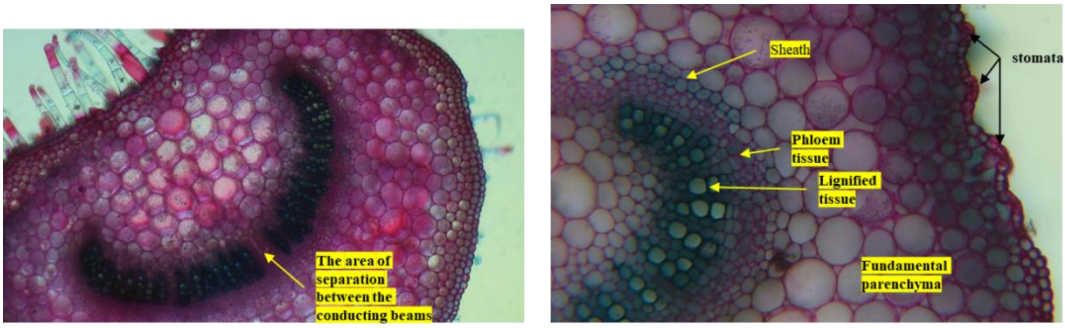

Fig. 2. Petiole of *Perilla frutescens* var. *frutescens* f. *viridis* - cross section view and detail (x100; x400)

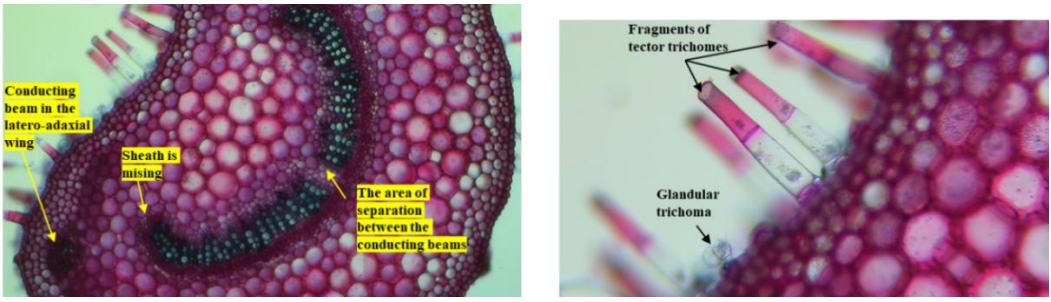

Fig. 3. Petiole of *Perilla frutescens* var. *crispa* f. *purpurea* - cross section view and detail (x100; x400)

Foliar Limb

In the cross-section of the foliar limb, the median rib protrudes strongly on the abaxial side to all three genotypes of *Perilla frutescens* (figs. 4, 5, 6). As in petiole at the level of the epidermis, there are lots of uniseriate pluricellular surface trichomes and less capitate glandular trichomes. Under epidermic layers, there are two-three sheets of angular collenchyma.

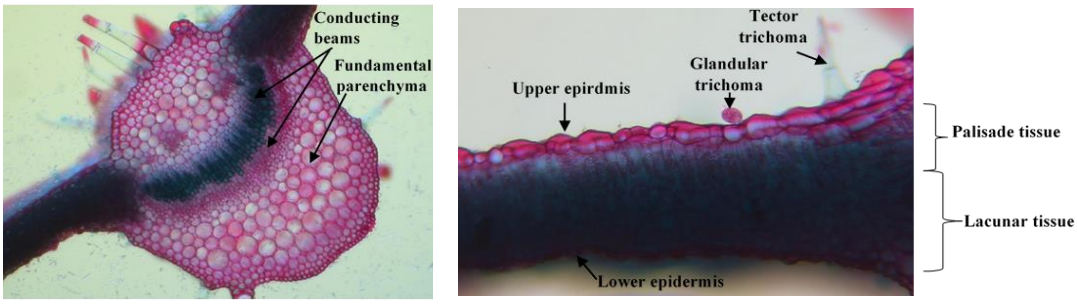

Fig. 4. Foliar limb of *Perilla frutescens* var. *frutescens* f. *viridis* - cross section view and detail (x20; x200)

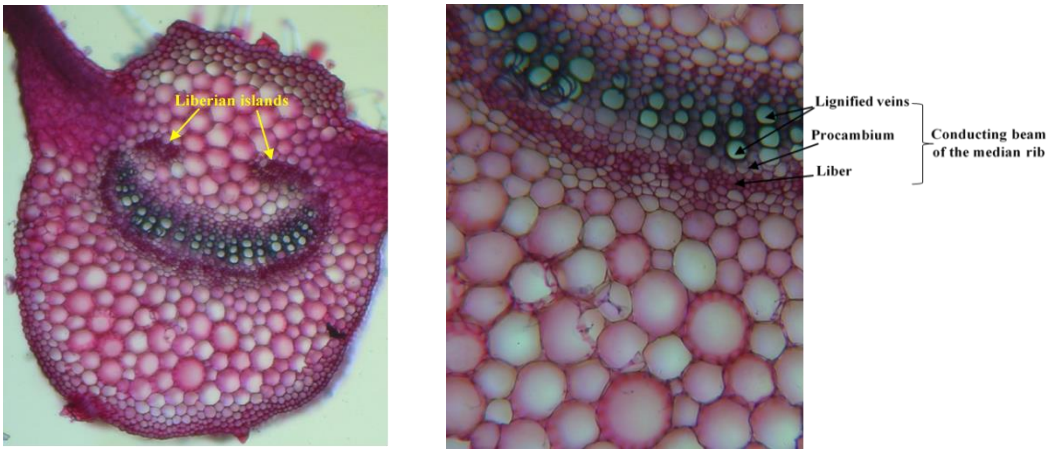

Fig. 5. Foliar limb of *Perilla frutescens* var. *crispa* f. *purpurea* - cross section view and detail (x100; x400)

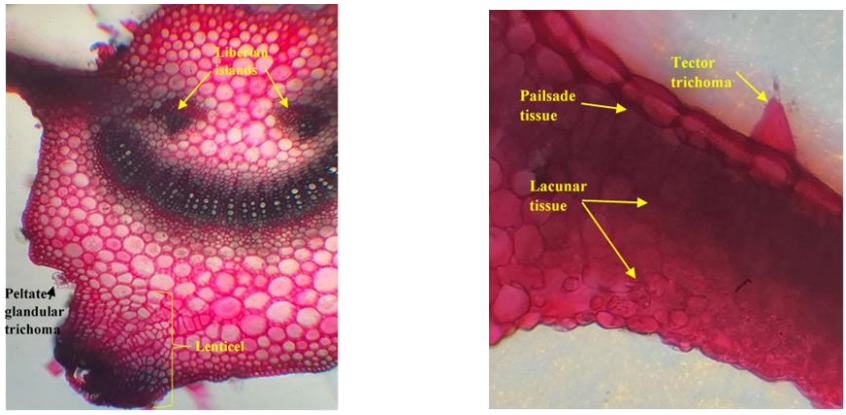

Fig. 6. Foliar limb of *Perilla frutescens* var. *frutescens* f. *crispidiscolor* - cross section view and detail (x100; x400)

Unlike in petiole, in foliar limb, there is only one conducting tissue orientated with phloem tissue to abaxial side and with lignified tissue to adaxial side. Near big principal conducting tissue there are two phloem mass orientated to the adaxial side of the median rib.

The last characteristic is not applied to *Perilla frutescens* var. *frutescens* f. *crispidiscolor*, which besides the two-phloem mass near the principal conducting tissue has two phloem-lignified small beams on both sides (fig. 7). This finding can represent an histo-anatomical character that identifies *Perilla frutescens* var. *frutescens* f. *crispidiscolor*.

In-between the veins, under the upper epidermis there is palisade tissue, the exterior layer being compost by higher cells. Under the lower epidermis, there is multi-layered lacunar tissue. Having these two characteristics we can conclude that the perilla foliar limb has a hetero-facial structure. The palisade tissue occupies

two-thirds of the thickness of the foliar limb, so the leaf realized a quality photosynthesis activity.

For a better and more detailed understanding of perilla leaves structure we used scanning electronic microscopy. The characteristics obtained from the three genotypes are summarized in table I.

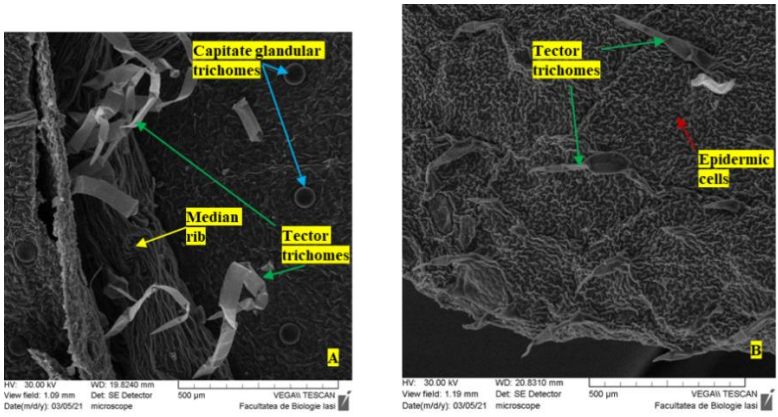

Fig. 7. SEM of *Perilla frutescens* var. *frutescens* f. *viridis* leaf: A - lower epidermis, B - upper epidermis.

TABLE I

Anatomical characteristics of genotypes of Perilla frutescens species on electronic microscope scanning

The samples	Lower epidermis	Upper epidermis
Perilla frutescens var. *frutescens* f. *viridis* (Fig. 7)	- capitate glandular trichomes, are located between the secondary veins, with the glandular part, covered by a smooth cuticle; - uniseriate pluricellular surface trichomes arranged along the ribs, very rarely between the secondary veins; - stomata are present (hypostomatic limb).	- uniseriate pluricellular surface trichomes are observed between the secondary veins; - glandular trichomes are missing between the secondary veins; - stomata are absent.
Perilla frutescens var. *crispa* f. *purpurea* (Fig. 8)	- capitate glandular trichomes are present between the secondary veins; - surface trichomes are missing between the secondary veins; - stomata are present (hypostomatic limb)	- rare mono/multicellular surface trichomes are placed between the secondary veins; - very rare capitate glandular trichomes are located between the secondary veins; - stomata are absent.
Perilla frutescens var. *frutescens* f. *crispidiscolor* (Fig. 9)	- peltate glandular trichomes are located between the secondary veins; - uniseriate pluricellular surface trichomes are arranged along the ribs; - stomata are present (hypostomatic limb).	- glandular trichomes are missing; - short unicellular surface trichomes are located between the secondary veins; - uniseriate long pluricellular surface trichomes are located between the secondary veins; - stomata are missing.

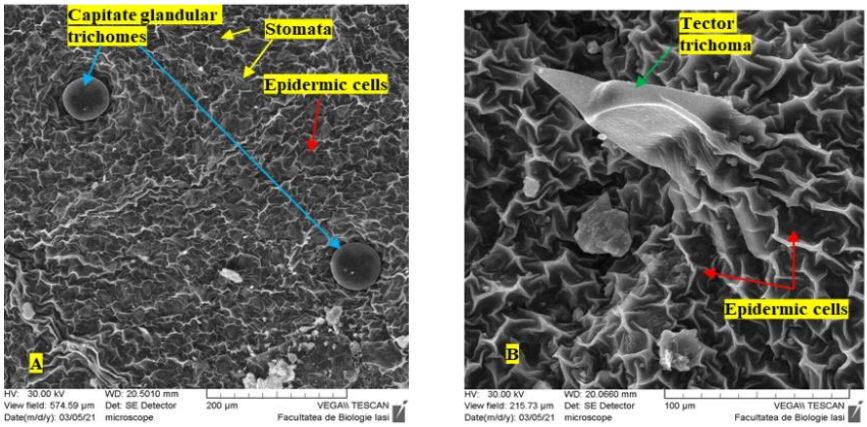

Fig. 8. SEM of *Perilla frutescens* var. *crispa* f. *purpurea* leaf:
A - lower epidermis, B - upper epidermis.

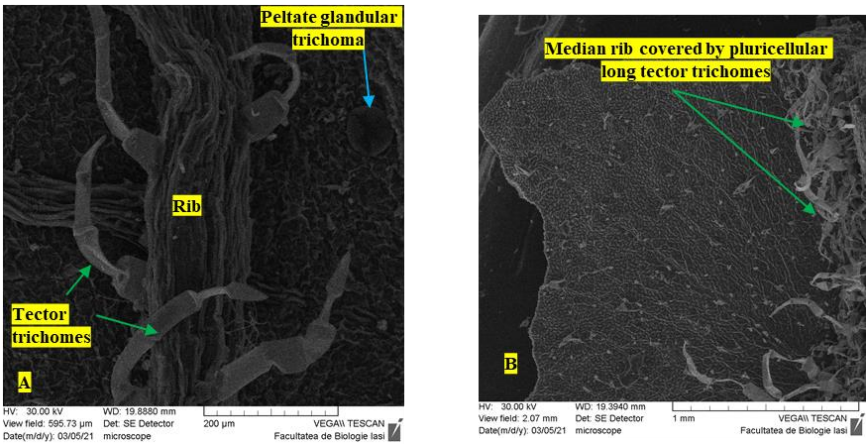

Fig. 9. SEM of *Perilla frutescens* var. *frutescens* f. *crispidiscolor*:
A - lower epidermis, B - upper epidermis.

CONCLUSIONS

Appling the histoanatomical investigation using an optical microscope and scanning electron microscope to the three types of *Perilla frutescens*, we obtained morphological characteristics that presented the similarities and differences for the three ones. As far as we know, there is no such study that involves perilla leaves. The described characters could have taxonomic value in the Lamiaceae family.

There are no significant differences between the three genotypes. Cross-section shape epidermis, stomata, angular collenchyma, and conducting tissue organization are mostly the same. An important finding that can help us correctly identify *Perilla frutescens* var. *crispa* f. *purpurea* is the absence of the sclerenchyma sheath at the level of the two large convex conducting tissue.

Also, we discover that *Perilla fru-*

tescens var. *frutescens* forma *crispidiscolor* has the most peltate glandular trichomes and so offers a bigger quantity of volatile oil. Other characteristics that helped us to recognized *Perilla frutescens* var. *frutescens* forma *crispidiscolor* were the two small phloem-lignified beams located on either side of the fascicular convex arch of the median rib.

These features, which are important for general level taxonomic classification, represent the novelty of our research. However, the chemical composition and pharmacological effects of the extract, which are closely related to the similarities and differences between the three genotypes of *Perilla frutescens*, still need to be further studied.

CONFLICT OF INTEREST AND FUNDING

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

MODERATE HYPOFRACIONED VS. CONVENTIONALLY FRACTIONED RADIOTHERAPY IN BREAST CANCER

Recently, a group of oncology specialists undertook a critical review that included data from 149 articles on the use of moderately hypo fractionated post-operative radiation therapy for breast cancer in clinical practice. The main aim of this study is to provide an overview of the applicability of moderately hypo fractionated RT for breast cancer patients, focusing on factors influencing clinical decision-making. They conclude that moderately hypo fractionated RT to the breast, chest wall (with/without breast reconstruction), and regional lymph nodes is at least as safe and effective as conventionally fractionated regimens and could be considered as the treatment option for the vast majority of the patients. For those who are still concerned about its generalized application, we recommend participating in ongoing trials comparing moderately hypo fractionated RT to conventionally fractionated RT for breast cancer patients in some clinical circumstances. The conventional radiation doses ranged from 50 to 50.4 Gy, given in 25-28 fractions over a course of 5-6 weeks. This empirical schedule assumed that a total dose around 50 Gy, prescribed in 1.8-2.0 Gy fractions, might maximize tumor control while minimizing normal-tissue injury. The results of six randomized phase III trials that were published with formal comparisons between moderate hypofractionation and conventionally fractionated irradiation for breast cancer patients The conventionally-fractionated whole breast irradiation 50 Gy in 25 fractions or hypo fractionated whole breast irradiation 42.56 Gy in 16 fractions was used. The patients in the conventionally fractionated whole breast irradiation group received a boost of 10-14 Gy (in 5 or 7 fractions, respectively), and those in the hypo fractionated whole breast irradiation group received 10-12.5 Gy (in 4 or 5 fractions, respectively). There were no significant differences between the conventional fractionation group and the 41.6 Gy hypofractionation group. Likewise, other side effects (such as shoulder stiffness, arm oedema, and breast shrinkage) were similar between the hypofractionation and conventional fractionation groups. Normal-tissue effects, such as breast oedema, telangiectasia, and breast shrinkage, were significantly less common in the hypofractionation than in the conventional fractionation group; no significant differences existed in arm oedema, shoulder stiffness, or breast induration. This pragmatic trial design, employing a biologically estimated lower dose led to, not surprisingly, a lower rate of acute side effects as the total dose was reduced, but it also produced lower late normal tissue side effects, which are more dependent on dose per fraction. Importantly, local control was at least as good. Overall survival was unexpectedly better, raising the exciting hypothesis that a shorter overall treatment time could be beneficial for survival, which could not be concluded in view of the non-inferiority design of this trial for local control. The critical review concludes the fact that existing data confirms that moderately hypo fractionated RT for breast cancer is efficient, convenient and safe for all indications, target volumes and techniques, with most evidence available for 2D- and 3D techniques for treatment of the breast and the chest wall, with and without a boost. Based on a more limited set of data, combined with radiobiological considerations, they recommend extrapolating these results to other indications, target volumes and techniques including regional nodal irradiation and treatment after mastectomy with or without breast reconstruction (Nader Marta GN, Coles C, Kaidar-Person O, *et al.* The use of moderately hypo fractionated post-operative radiation therapy for breast cancer in clinical practice: A critical review. Published online 2020 Aug 26. doi: 10.1016/j.critrevonc. 2020. 103090).

BIOMIMETIC COMPLEX CREAM FORMULATION, PROPERTIES, TOLERANCE AND MOISTURIZING EFFECTIVENESS ON SKIN

BIOMIMETIC COMPLEX CREAM FORMULATION, PROPERTIES, TOLERANCE AND MOISTURIZING EFFECTIVENESS ON SKIN (Abstract): This study consisted of developing and evaluating a new biomimetic cream with vitamins, hyaluronic acid and active phytocomplexes from different plants, such as *Centaurea cyanus, Aloe barbadensis, Achillea millefolium and Spilanthes acmella*. Efficiency of the new formulated products was demonstrated by testing the hydration degree of human subjects' skin. **Material and methods**: It were developed a lipophilic cream with a 64% hydrophilic phase and 36% lipophilic phase and a new type of lipophilic emulsifier. The physico-chemical properties (appearance, pH), technological parameters (consistency, spread ability and rheology) and *in vivo* moisturizing effect were evaluated. **Results**: The proposed moisturizer cream presented a pleasant texture and a pH of 7.1. From the rheological behavior, it can be seen that the product can be easily applied to the skin and in terms of effectiveness the results are excellent. After a single application on dry skin, the proposed formulation can improve by 80% the degree of hydration. **Conclusions:** The developed water/oil biomimetic formulation, which has a pH compatible with the skin, is easy-to-apply and have a very good tolerance on dry skin with immediate hydration. **Keywords**: BIOMOMETIC, COSMETIC CREAM, SKINCARE, MOISTURIZING EFFECT.

The process of aging in the skin causes certain changes: the quality of the skin's support matrix tends to change, the endogenous water retention capacity decreases, the dermal fibers tend to atrophy, and the skin becomes dehydrated and loses its elasticity (1). The main role of cosmetic product after application, is to help remedy these changes and to maintain healthy skin, through the supply of water that it provides from the outside. The use of water/oil (W/O) creams is generally indicated for all

skin types, especially for dry skin, where it is a necessity, they also replace the lack of natural secretion of fat from the skin. The creams, through their composition, correct dryness and restore elasticity, especially through the content of emollients that soften the skin (the stratum corneum), helping to maintain its suppleness by delaying the dehydration process. Skincare also aims to provide as pure fat as possible, to replace those that have been removed by numerous washes. Regardless of their mode of action, the creams have been broadly called emollients, but the term may include multiple categories of creams (2-4).

When formulating and preparing cosmetic creams (emulsifying systems) the aim is to ensure the following conditions: not be irritating (avoid irritating substances); to be formulated with the help of excipients and active substances capable of deep hydration; to be able to incorporate biologically active substances, favoring their penetration into the skin; be prepared with the best quality raw materials, brought in a state of fine division, to ensure penetration into the skin; not rancid easily, otherwise causing skin irritation and redness; be suitable for the skin on that it is applied; to make a protective layer on the skin, both in summer and in winter, having at the same time an emollient action; not to be overly fragrant (5-12).

The latest trend in cosmetics is biomimetic creams because are the key to effective and sustainable skincare. The term of biomimetic come from the prefix "bio" which refers to natural while "mimetic" is derived from the word "imitate". Biomimetic cosmetics include all kinds of products that are formulated in such a way as to adapt to the structure of the skin. Only natural cosmetics aren't always the most sustainable, and pharmacies can use biomimetics to formulate new alternatives that are more sustainable with less environmental impact. In addition to anti-aging skincare, biomimetics has also been crucial in creating better moisturizing products for people who suffer from chronic dry skin. Niacinamide improve overall skin texture by rebuilding a lipid layer, minimizing the appearance of pores, preventing UV damage and inflammation as an antioxidant (9*). Spilanthes acmella* flower extract works as key system because stimulates the production of normal moisturization factor in the skin and achieves moisturization rather than being a topical hydrator. This biomimetic ingredient is a concentrated firming and wrinkle which stimulates the filaggrin (13). Targets cell communication to reorganize and retighten the dermal architecture. Has a natural lifting and smoothing effect, visibly reducing deep wrinkles and firming the skin. The concept of biomimetics products goes beyond basic product formulation by delivering a synergistic combination of phospholipids, pre/probiotics, natural moisturizing factors, skin-identical lipids, peptides, vitamins, or amino acids.

The main role of creams is to moisturize and maintain healthy skin, by providing water from the outside, after application (14). The choice of a cosmetic cream by a consumer is the combination of good marketing and proven product quality to gain notoriety, consumer attention, last but not least, the satisfaction of commercial interest (15-17). The quality and attractiveness of a cosmetic product are decided by factors such as its texture, appearance, smell and performance. The objective evaluation of cosmetics has attracted increasing attention lately, on the one to hand, to improve

their performance and on the other hand to meet the requirements of legislation requiring continuous and scientifically substantiated proof of the claims used in marketing on quality of the products. This information can be obtained through the rheological study and the ability to spreadability on the skin. These characteristics can influence the quality of the cosmetic product and even its effectiveness.

The aim of this study consisted of developing and evaluating a biomimetic formulation, which constantly applied to the skin produce a moisturizing effect.

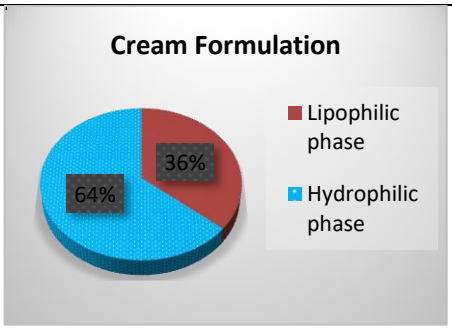
MATERIAL AND METHODS

A W/O cream with moisturizing properties was developed and analyzed. The cosmetic product contains 64% hydrophilic phase and 34% lipophilic phase, emulsify system in which the following ingredients have been incorporated: vitamins, hyaluronic acid, and active phytocomplexes from *Achillea millefolium* oil, *Cocos nucifera* oil, *Argania spinose* kernel oil, *Spilanthes acmella* flower extract, *Centaurea cyanus* flower water and *Aloe barbadensis* leaf juice. The physical-chemical properties (appearance, pH - determined with a digital pH-meter), technological parameters (consistency - determined with a semi-automatic Penetrometrer, spreadability - determined with an extensometer, and rheological parameters, determined using a Rheotest equipment) and the moisturizing effect (*in vivo* studies on human subjects using a Corneometer) were investigated.

TABLE I

Creams composition

INGREDIENTS	(%m/m)
Lipophilic phase	
Achillea millefolium oil	10
Cocos nucifera oil	7
Argania spinosa kernel oil	7
Methyl Glucose Sesquistearate	5
Stearic acid	3
Spilanthes acmella flower extract	1
Glyceryl Stearate SE	2
Tocopherol	1
Hydrophilic phase	
Centaurea cyanus flower water	40
Aloe barbadensis leaf juice	20
Niacinamide	2
Hyaluronic acid	2



Centaurea cyanus flower water (Logis-Tech Jolanta Czepulonis, Poland), *Aloe barbadensis* leaf juice (Fagron, Greece), *Achillea millefolium* oil (Fagron, Greece), *Cocos nucifera* oil (Fagron, Greece), *Argania spinos*a kernel oil (Fagron, Greece),

Stearic acid (Vitamar, Romania), Methyl glucose Sesquistearate (Evonik Industries, Germany), Glycerol (Vitamar, Bucharest, Romania), *Spilanthes acmella* flower extract (HerbPharm, India), Niacinamide (Fagron, Greece), Glyceryl Stearate SE (Evonik Industries, Essen, Germany), Tocopherol (Medchim, Romania), Hyaluronic acid (Fagron, Greece).

Cosmetic cream preparation

The emulsifier, Methyl Glucose Sesquistearate (MGS) was dispersed in the lipophilic phase, heated to 65°C and then the hydrophilic phase was incorporated at the same temperature.

pH measurement

Samples of 5.0 g cream were heated in 15 g of distilled water until the fat phase melted, stirred for one minute, cooled to 20 °C and filtered through filter paper. The pH of the aqueous filtrate was measured using Consort C831 multiparameter analyzer. The results shown for each cream represent the average of 6 measures.

Rheological analysis

The spreadability of the prepared formulation was determined using a extensometer. The sample with a uniform thickness was placed between the two glass slides and pressed with different weights were placed on the upper side and then drawing the appropriate curves (18). Consistency assessment was performed using a penetrometer (PNR 12 Petrolab, Germany) with a micro cone and a suitable container (19). All measurements were carried out in triplicate. The rheological characteristics evaluation of the prepared formulations was carried out using a rheometer Rheotest RV (RHEOTEST Medingen GmbH, Germany), provided with coaxial cylinders operating with twelve shear rates (20).

Moisturizing test

The instrument used to measure the hydration level was Corneometer® CM 825 (Courage + Khazaka). Due to its ease of use and short measurement time, this device is the most widely used system in the world to determine the level of hydration on the surface of the skin and especially in the stratum corneum. The device runs at an average frequency of 1Mhz, between 0.95 MHz (very hydrated medium) and 1.15 MHz (very dry medium). The device is equipped with a 0.64 cm^2 probe consisting of a 75 μm network of gold electrodes, coated with a vitrified material with a low dielectric constant. The probe exerts a constant pressure of about 1.5 N on the skin and covers an area of 49 mm^2. Measuring the degree of hydration with this device is based on measuring the capacity of a dielectric medium. Uses field capacity sensors to measure the dielectric constant of the skin. The dielectric condition of the skin will change with the water content. This allows you to measure any changes in skin hydration through the precision measuring condenser. These changes in the water content of the stratum corneum are transformed into arbitrary units of hydration. There is a piece of fine glass on the probe head to make sure that only the capacities are changed due to the water content. Even small changes in the water can be detected. The measurement time is short at only one second, minimizing the effects of occlusion. The depth of measurement was 10-20 μm in the stratum corneum, so the deeper layers of skin do not influence the measurement (21, 22).

The moisturizing effect was *in vivo* test on eight subjects. The evaluation of the hydration grade of the stratum corneum indicated that the products have a moisturizing effect four hours after application. The study was carried out under the responsibility of a dermatologist following the protocol, the principles of good clinical

practice, international recommendations ICH E6 (R1) of 10.06.1996, Directive of the European Parliament, and the Council 2001/20 / EC-OJ / EC of 01.05.2001), in ethical conditions towards the subjects, they preliminary filling in an informed consent form (23).

Statistical data analysis

For absolute variations compared to T_0 ($\Delta = T_i - T_0$), the following parameters were defined or calculated for the treated area and for each experimental time (T_i): number of subjects (n), mean, standard deviation, minimum and maximum values. The data were analyzed with *SPSS* software *Windows version*. For statistical analysis, the degree of significance of 5% was used (tests with paired data - statistical significance: p value <0.05), and for normality tests 1%.

RESULTS

In this study, a cosmetic cream with an emulsifying system W/O has been developed with a pleasant, homogeneous appearance and odor, without signs of phase separation or foaming.

pH measurement

The tested formula has a pH = 6.8. The value of pH is used in W/O creams so that it can be applied around the eyes without causing stings due to the pH.

Rheological analysis

The analysis of the rheological properties of the proposed cosmetic formulation showed a plastic behavior (fig. 1). The spreadability and consistency curves are presented in second figure.

Moisturizing effect

To perform the hydration test on human subjects using a corneometer, only those with dry skin are chosen from a panel of healthy subjects, those with a corneometric index value higher than 35-40.

From the experimental data obtained and presented in second table, S_2 and S_4 subjects can be excluded.

Comparative interpretation of research results: for each experimental time (T_1, T_2, T_3, T_4) the relative variations of the corneometric index (compared to T_0) were calculated according to the following formula:

$$\Delta\% = [(T_i - T_0) * 100] / T_0$$

The hydration efficiency, after applying the cosmetic products, is expressed by average corneometric index (I), as well as the variation% compared to T_0 are shown in fourth figure.

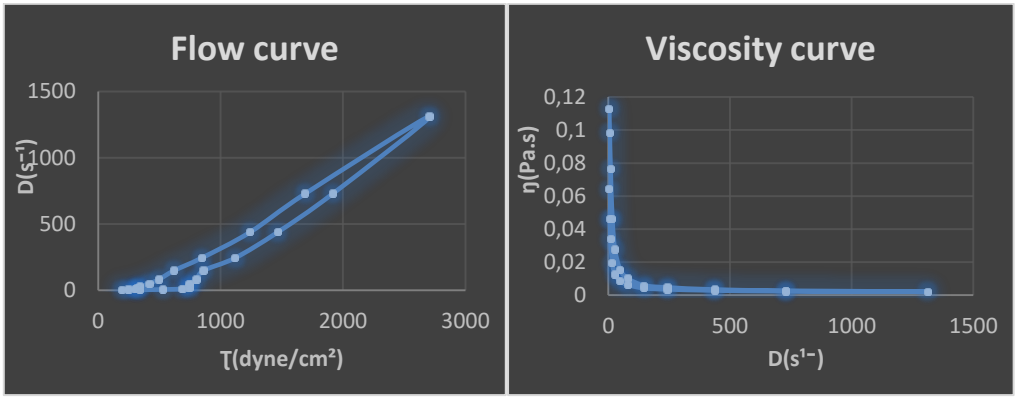


Fig. 1. Rheological behavior of the biomimetic cream

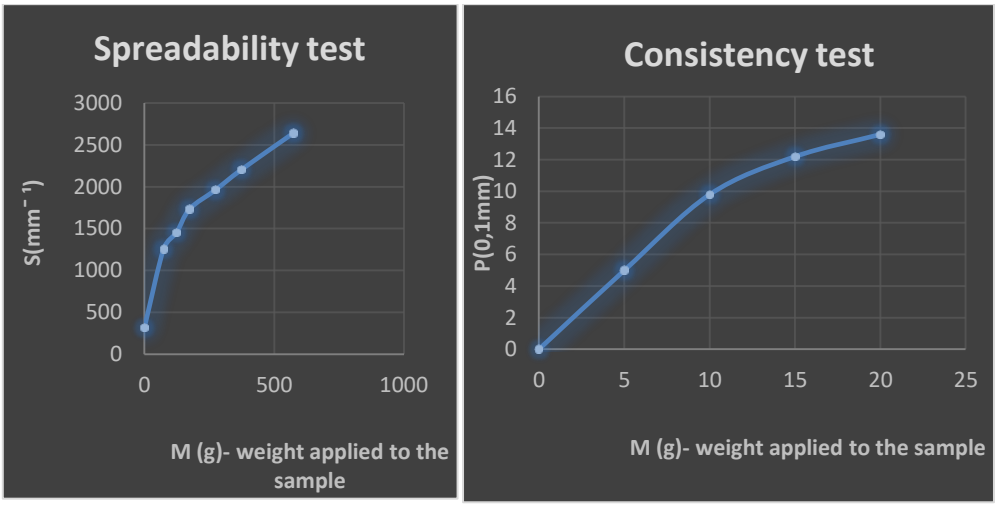

Fig. 2. Spreadability and consistency of the biomometic cream

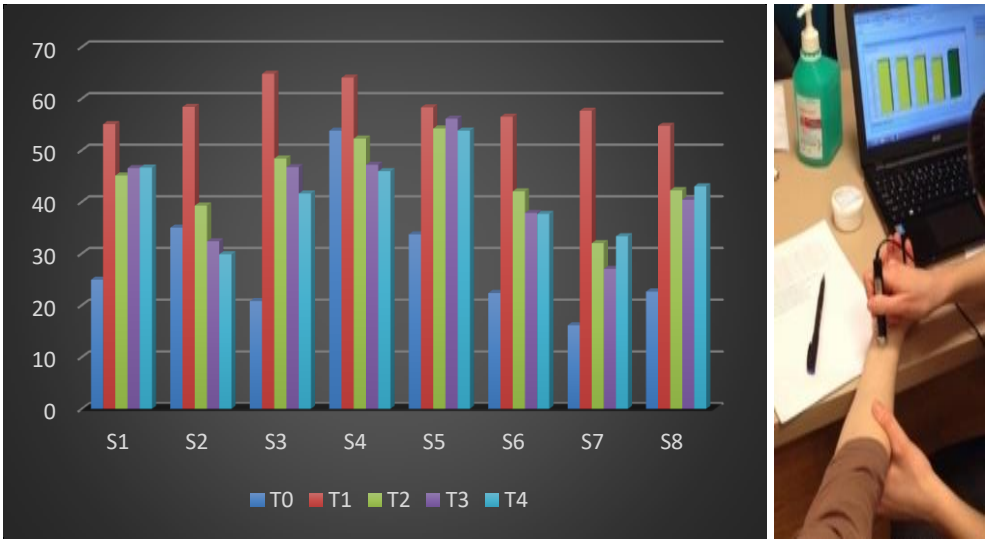

Fig. 3. Corneometer index measured at different time after cream application

*T_0 - before cream application; T_1 - immediately after cream application; T_2 - at 30 minutes after cream application; T_3 - at 2 hours after cream application; T_4 - at 4 hours after cream application

TABLE II.

The size of the variation of the hydration effect on the treated area

Human Subjects	Variation of corneometric index (%)			
	T_1 *vs.* T_0	T_2 *vs.* T_0	T_3 *vs.* T_0	T_4 *vs.* T_0
S_1	121.08	81.08	86.90	87.22
S_2	66.85	12.28	-7.57	-14.74
S_3	211.53	132.69	124.61	100.00
S_4	19.03	-2.86	-12.28	-14.66

Minimum	19.03	-2.86	-12.28	-14.74
Maximum	257.28	132.69	124.61	106.50

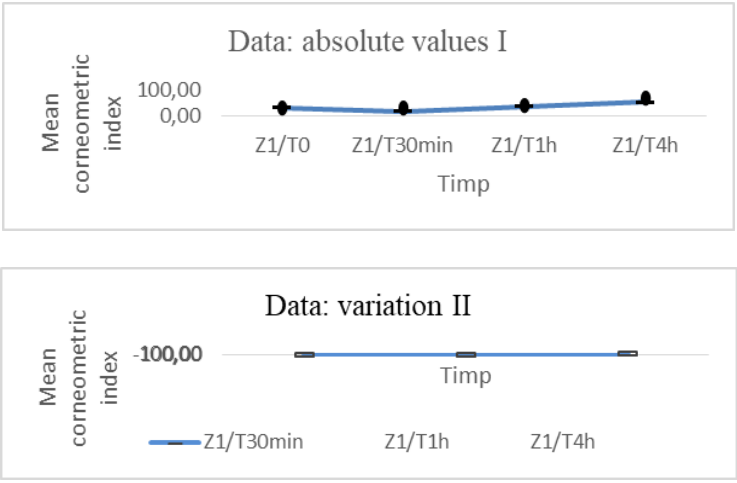

Fig. 4. Moisturizing efficiency after applying the cream

Following the correlations made with Dunnett t test, Z_1/T_0 -Z_1/T_1, Z_1/T_0 - Z_1/T_2, Z_1/T_0 - Z_1/T_3 and Z_1/T_0 - Z_1/T_4 there were no differences statistically significant.

TABLE III

Multiple comparisons after statistical interpretation data

(I) Time	(J) Time	N	Test	Average difference (I-J)	p value
Z1/T_1	Z1/T_0	8	Dunnett t	30,01	0,152
Z1/T_2	Z1/T_0	8	Dunnett t	15,77	0,069
Z1/T_3	Z1/T_0	8	Dunnett t	13,1	0,085
Z1/T_4	Z1/T_0	8	Dunnett t	12,8	0,176

DISCUSSION

Skincare with cosmetic products that contain mostly natural ingredients, without a high content of preservatives, is a desire of the first choice of users. The skin contains a large amount of water, respectively over 70%, of which 1/3 is found in the stratum corneum.

In our extensometry test the pressure is gradually exerted at the same time on the entire surface of the sample, unlike the penetrometer test in which the pressure is gradually applied to a single point on the surface of the sample. Practical, the extensometry curves show the ability to deformation throughout the bulk mass of the cream.

The cream shows a plastic behavior is observed for the prepared moisturizer, the increase of the tangential tension determines the decrease of the viscosity. When evaluating the restructuring behavior during shearing with successive decreasing speeds, a hysteresis loop was observed. The analyzed sample initially showed a high viscosity, but with the increase of the tensile stress, the viscosity decreases, with the destructuring of the system. Then, from the moment the tangential stress decreases, the viscosity begins to increase, with the restructuring of the system, but not with the same speed with which the destructuring took place.

From the experimental data obtained by the hydration test on human subjects only subjects with very dry skin were tested, because the capacity of a moisturizer cannot be determined if the skin is already hydrated or has excess sebum. After four hours to the application of the cream proposed in the study, the hydration level increased in S1 by 87%, in S3 by 108%, in S5 by 59%, in S6 by 68%, in S7 with 106%, and in S8 with 108%. Given that a moisturizer should theoretically improve hydration by 30%, it can be said that an average of over 80% is a very good percentage.

CONCLUSIONS

In this study a biomimetic cosmetic formulation, with 64% hydrophilic phase and 34% lipophilic phase, emulsive system in which the following ingredients have been incorporated like vitamins, hyaluronic acid, and active phytocomplexes from *Achillea millefolium* oil, *Cocos nucifera* oil, *Argania spinose* kernel oil, *Spilanthes acmella* flower extract, *Centaurea cyanus* flower water and *Aloe barbadensis* leaf juice, was developed, able to restore the optimal hydration level. The cream had a regenerating effect through its ingredients, the skin becoming more elastic and hydrated. Although, it is a W/O cream that does not leave the skin oily, the concentration of the lipophilic phase and the emulsifier used do not leave oily skin after application, the absorption of the components is maximum after application. The tested formula had a pH = 6.8 and it was observed a plastic flow.

In vivo tests confirmed the increase of the hydration level on average of 89% in comparison with T_0. Taking into consideration that a moisturizing cream has to improve the hydration by at least 30%, it can be concluded that over 80% hydration improvement is an optimal result.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

FINDINGS AND PERSPECTIVES USING ENCAPSULATION TECHNIQUES

The association between obesity and vitamin A has been studied. Some studies point to the anti-obesity activity related to this vitamin, carotenoids with provitamin A activity, and carotenoid conversion products. This performance has been evaluated in respect of adipogenesis, metabolic activity, oxidation processes, secretory function, and oxidative stress modulation, showing a new property attributed to vitamin A in preventing and treating obesity. However, vitamin A and its precursors are highly sensitive and easily degraded when subjected to heat, the presence of light, and oxygen, in addition to losses related to the processes of digestion and absorption. In this context, recognizing the instability of vitamin A and carotenoids with provitamin A activity in the face of environmental conditions, and thereby incorporating these bioactive compounds in encapsulating agents that bring stability and promote positive absorption effects, is a strategy of considerable interest. In this way, it is possible to expand this nutrient's use in food or pharmaceutical products, as well as potentiating the effects in the treatment of deficiencies related to vitamin A. Thus, it is believed that the encapsulation of vitamin A or its precursors brings essential benefits since it preserves and maintains functionality. It also favors these compounds' action in target tissues and/or organs, thus allowing these bioactive compounds to be better used in the treatment of obesity and associated comorbidities. (de Carvalho Gomes C, *et al.* Vitamin A Status Improvement in Obesity: Findings and Perspectives Using Encapsulation Techniques. *Nutrients* 2021; 13(6): 1921/ doi: 10.3390/nu13061921).

SIGNIFICANCE OF NON-HLA ANTIBODIES IN LOW-RISK KIDNEY TRANSPLANT RECIPENTS

This prospective study included total 94 recipients among 201 consecutive recipients who underwent an ABO-compatible living donor kidney transplant (LDKT). Angiotensin II type 1 receptor antibodies (anti-AT1R) and anti-endothelial cell antibodies (AECA) were measured before, during and after LDKT. The prevalence of acute rejection (AR) within 12 months post-transplant did not differ significantly based on anti-AT1R levels and AECA results. However, when a cut-off value of 11.5 U/mL was applied, it independently predicted a higher risk for AR. AECA (+) recipients had a higher risk for AR or microvascular inflammation (MVI) only during the follow-up period and also showed a rapid increase in creatinine and decrease in eGFR at approximately three months; after this point, they showed persistently higher creatinine and lower eGFR until 20 months. Pre-transplant anti-AT1R level was a significant risk factor for the development of AR, while AECA status was associated with impaired renal function regardless of AR. (Shinae Yu, *et al.* Pre-Transplant Angiotensin II Type 1 Receptor Antibodies and Anti-Endothelial Cell Antibodies Predict Graft Function and Allograft Rejection in a Low-Risk Kidney Transplantation Setting. *Ann Lab Med* 2020; 40(5): 398-408).

INFLUENCE OF CARBOPOL 971P NF ON FLOW RATE AND SWELLING PARAMETERS IN ANTIFUNGAL TABLETS

INFLUENCE OF CARBOPOL 971P NF ON FLOW RATE AND SWELLING PARAMETERS IN ANTIFUNGAL TABLETS (Abstract): The purpose of this research laid in developing oromucosal bioadhesive tablets with miconazole nitrate based on hydrophilic bioadhesive polymers, Carbopol 971P NF, capable to form a good adhesion to prolong the duration of the active ingredient action for several hours. The aim is to observe the correlation between the disintegration time, the swelling index and the amount of polymer used in mucoadhesive tablets. **Material and methods**: The tablets were made using direct compression method, the mucoadhesive tablets differing in the amount of Carbopol 971P NF. The first proposed formula (FI) contains 40 mg polymer and the second one (FII) contains 10 mg polymer. After the formulation and development of mucoadhesive tablets using different grades of polymer, physicochemical parameters such as surface area, thickness, diameter, friability, hardness, disintegration time and swelling index were determined. **Results**: Both proposed formulas have an optimal disintegration time of 75 and 98 minutes. The swelling index for FI (18% polymer) is 0.4435 and for FII (4.5% polymer) is 1.0316. **Conclusions:** Considering that the mucoadhesive tablets imply a swelling index over 1 and a longer disintegration time, the FII formula, with 10 mg carbomer, can be considered optimal. **Keywords**: CARBOPOL 971P NF, MUCOADHESIVE TABLETS, ANTIFUNGAL TABLETS, MICONAZOLE NITRATE.

The proliferation of stressful conditions, as a result of the diversification of new activities in human society with the appearance of the corresponding noxious substances, as well as the diversification of microbial species, mainly due to the rapid

movement of large numbers of people around the globe, has led to the emergence and intensification of fungal infections.

Many fungi have low virulence and only cause superficial infections of the outer layers of the skin, where antibodies and immune cells cannot reach. Although these infections are not serious, they are very common. These infections are usually chronic or recurrent if the underlying cause has not been eliminated and can become very stressful for patients.

Increased susceptibility to infection has been reported in people whose immune systems are physiologically impaired or as a consequence of a disease or treatment, or whose natural defenses and normal microbial flora have been affected. The incidence of fungal infections in immunocompetent organisms with a severely compromised immune system has also been observed.

It is now noted that the most common fungal infections in humans are urinary, vaginal and oromucosal. In recent years, their etiology is changing. If a decade ago they were produced almost exclusively by *Candida albicans* (85-90%), today non-albicans strains of *Candida* are increasingly involved (1, 2).

Miconazole nitrate is a topical antifungal agent used for local treatment of vaginal, skin and nail infections due to yeasts and dermatophytes, being active against *Candida* spp., *Trichophyton* spp., *Epidermophyton* spp., *Microsporum* spp. However, oral administration of drugs has disadvantages, such as metabolism of the first hepatic passage and enzymatic degradation within the gastrointestinal tract. These disadvantages may limit or prevent the oral administration of certain drugs, especially peptides and proteins, when they are inserted into special colon administration systems (3). These limitations have led to the exploration of other mucous membranes as potential locations for drug absorption (4). The mucosal routes of drug administration (e.g., mucosa of the nasal, rectal, vaginal, ocular and oral cavities) offer various advantages over oral administration of drugs (5, 6). These benefits include possible alternative pathways for the first-pass effect and avoidance of presystemic elimination within the gastrointestinal tract (7, 8).

Strategies for oral administration of drugs are represented by the new oral dosage forms, which consist mainly of sustained release systems for oral administration, designed to deliver the drug over a period of time (9, 10).

Mucoadhesive tablets are widely used in the formulation and preparation of topical antifungal products for prophylactic or curative purposes in infections of the oral and pharyngeal mucosa, such as acute oral candidiasis. This oral candidiasis is a major problem for patients with long-term HIV infection, with corticosteroid, antibiotic, anti-inflammatory agents treatment (8).

To improve the bioavailability of active substances in the oral cavity, various bioadhesive tablet systems have been developed in recent years with different active substances. Oral tablets can be applied in the oral cavity, for example in the palate, the mucous membrane of the cheeks, and the upper lip and the gums. They soften and adhere to the mucosal substrate is retained in the fixed position until complete dissolution and/or complete release. After a while, the patient no longer feels the tablet in his mouth. The location of the tablet in the mouth seems to have a big impact on tolerance and retention time. Depending on the location, either palatal or gingival, the retention time varies from 20-40 minutes to

7-12 hours.

It is important that excipients for the development of tablets do not stimulate salivation, as in this case much of the drug may reached the gastric level, instead of being available locally and absorbed. Thus, the main characteristic of bioadhesion is the force of the attachment of the pharmaceutical form to the biological tissue and this is obtained by using polymers that adhere to the mucin-epithelial surface. Oral mucoadhesive tablets are modern modified-release pharmaceutical forms used in current therapy, to achieve a controlled release of the active substance at the site of application as a result of maintaining the pharmaceutical preparation at this level. The principle of formulation of modified release bioadhesive tablets is to disperse the active substance in various hydrophilic polymeric matrices.

Many oral products on the pharmaceutical market use carbomers as polymers for bioadhesion due to the benefits of this kind of formulation (11). Carbopol-type polymers have different rheological properties, influenced by particle size and molecular weight. The rheological properties can be related/correlated with the molecular weight of the polymer. Carbopol 940, 941, 971 and 934 are types of polymers very well tolerated by the body without toxic effects. The resulting levels should be low those shown to have no risk to human health. For example, in a toxicology study of Carbopol® 974P NF polymer with dogs, the no observed adverse effect level was 50,000 ppm (12). Carbopol® 971P NF polymer (tab. I) is used in oral and mucosal applications such as extended/controlled release tablets, oral liquids, and suspension and bioadhesive formulations (13).

TABLE I.
Physico-chemical properties of Carbopol 971P NF

Appearance	white power	
Density	208 kg/m^3	
Specific weight	1.41	
Humidity	2.0% maximum	
pKa	6.0 ± 0.5	pH value (1% solution at 25°C)	2.5 - 3.0	
pH value (0.5% solution at 25°C)	2.7 - 3.5	
Equivalent weight	76 ± 4	
Ash content	0.009 ppm (average)	
Glass-transition temperature	100-105° C	

The research was focused on the development of solid pharmaceutical forms, such as oral mucoadhesive tablets with miconazole nitrate, and the changes that occur regarding the disintegration time and swelling index using different excipients.

MATERIAL AND METHODS

The following substances were used to develop mucoadhesive tablets: miconazole nitrate 99% (Sigma Aldrich, Germany), Carbopol 971P NF (Lubrizol, USA), mannitol (East Chemical, China), aerosil (Degussa, Germany), and magnesium stearate (Sigma Aldrich, Germany). Miconazole nitrate was used as an antifungal active substance of mucoadhesive tablets, which were prepared according to table II in two formulations.

TABLE II.

Formulation of mucoadhesive tablets with miconazole nitrate

Ingredients (mg/tablet)	F I	F II
Miconazole nitrate	50	50
Carbopol 971P NF	40	10
Mannitol	122	152
Aerosil	6	6
Magnesium stearate	2	2
Total weight (mg) 220		

Determining the flow rate and compressibility parameters of powder mixtures

There were monitored the typical parameters: flow rate (t), friction coefficient (tg α), repose angle (α), Hausner ratio (HR) and Carr index (CI).

Flow rate (t) the time needed for 100 g of formulation to flow through a funnel with a 10 mm orifice;

Friction coefficient (tg α) – dynamic method, according to the equation:

$tg\ \alpha = h/r$

where: h = height and

r = radius of the cone

Repose angle (α) – dynamic method;

Haussner ratio (HR) – calculated by determining the density before and after settling, according to the equation:

$HR = pt/pi$

where: pt = density after settling and

pi = initial density

Carr index (Ci) – identical determinations and recordings with the ones presented in Haussner ratio, but calculated according to the equation:

$CI = (pt-pi/pt)x100$

Preparing the oromucosal bioadhesive tablets with miconazole nitrate

Mucoadhesive tablets were made by using the method of direct compression of the powder mixture with a Korsch tablet equipment double-sided press (size of upper punch φ = 9 mm) to a compression pressure of 5 – 6 kN, for 30 seconds.

Characterization of the oromucosal bioadhesive tablets with miconazole nitrate

Dimensional characteristics. The dimensions of the tablets: diameter (d^2) in mm and height (h) in mm were determined using the automatic device PHARMA-TEST, Germany, on a number of 10 tablets and the average was calculated. The surface area of the tablets was then calculated according to the formula:

$S=\pi*d^2/4$

Resistance to crushing. The resistance to crushing of mucoadhesive tablets was also automatically determined in PHARMA-TEST device.

Friability. Also called tablet wear, it is obtained after exposure to rolling the tablet. Due to the phenomenon of rolling some of

the particles of the tablet fall off. The phenomenon is also known as an abrasion and is expressed as a percentage. The friability is calculated according to the formula:

$$\text{Friability} = (\text{Initial weight} - \text{Final weight}) / \text{Initial weight} \times 100$$

Disintegration. According to USP 32 method A, the test was carried out on a number of 6 tablets of each formula. *The Pharmacopoeia* provides the determination on 6 tablets which are placed in a 500 mL conical vessel with 300 mL of water maintained at a temperature of 35-39°C. During the determination, the vessel is shaken gently twice a minute. After four hours, the contents of the vessel is filtered through a 0.8 mm mesh sieve, the vessel is washed with 300 mL of water at 37±20°C, which is brought over the remaining particles from the disintegration. It is allowed to remain on the sieve particles, which when lightly pressed with a flattened wand at one end pass through the sieve. If the result of the determination is negative, the test is repeated twice with 6 tablets each, establishing the duration of disaggregation for both determinations. The product is considered suitable if the average of these two determinations does not exceed the expected time by more than 20%. The disintegration test determines the time required to turn the tablets into fine particles or the time required to release the contents of the capsule wrapper when they are placed in a liquid medium under specific working conditions.

Swelling index

The swelling index (SI) of a mucoadhesive preparation is an important parameter for evaluating the prolonged release of the drug and the adhesive action. The swelling index of the mucoadhesive tablets has been determined by weighing only one of the two formulas and recording the weight before placing them separately in Petri dishes. The individual initial weight was marked with (W1). In each dish, we added 15 mL of phosphate buffer (pH=6.8) and the temperature was thermostatically maintained at 37°±0.5°C. At regular intervals (60 minutes, 120 minutes), the tablets were extracted, and excess surface water was removed, carefully and weighed again (W2).

The swelling index was calculated for each formulation, using the formula:

$SI = (W2-W1)/W1 \times 100$

where: W1 = the initial weight of the tablet and W2 = the weight of the tablet after 60,

respectively, 120 de minutes at 37ºC in phosphate buffer solution.

Statistical data analysis

Statistical analysis of the data was performed using IBM *SPPS 20* software.

RESULTS AND DISCUSION

Determining the flow rate and compressibility parameters of powder mixtures

The first parameter that was determined for the flow behavior of the powders according to the cohesive material was the value of the repose angle. If a particle is temporarily outside this limit angle, it can slide to the adjacent surface under the influence of gravitational force until the shape of gravity is balanced by the friction between the particles. The lower the repose angle value, the lower the powder flow rate. Thus, a value of the angle below 20 indicates an excellent flow and a value between 20-30 indicates a good flow and up to 40 a poor flow rate. FI formulation contains 40 mg polymer compared to 10 mg of polymer in FII, and this matrix-

forming polymer makes it difficult for the powder to flow even if it contains aerosol and magnesium stearate (tab. III).

TABLE III.
Flow rate and compressibility parameters for FI and FII formulations

Formulation	Parameter			
	α (º)	tg α	HR	CI (%)
FI	41.9	0.90	0.8800	13.99
FII	36.80	0.73	0.8300	18.65

The Haussner ratio is the ratio of the density of the final powder bed to compaction and is based on the friction between the particles which demonstrates a good or less good yield. Thus, in all formulations the result of the Haussner ratio is below 1.2 which indicates a slight flow. We can see a better flow in the FII formula with a smaller amount of polymer (tab. III).

The Carr index, also called the compressibility index, is closely related to the Haussner ratio, which is another parameter of the fluidity of the powder mixture that indicates the need to add a thinner or not. According to specialized monographs, CI with a value between 5-12 means an excellent flow of the powder and between 12-16 a good value for flow. Compressibility is the ability of a powder to decrease its volume instantly, under a pressure applied vertically (14-21).

Characterization of the oromucosal bioadhesive tablets

The macroscopic characteristics of the mucoadhesive tablets made have flat, uniform, flat-rimmed, flat-surface lenticular discs, which means that these pharmaceutical forms are suitable both in terms of Romanian Pharmacopoeia Xth edition (FRX) and optimal for administration to the oral mucosa. The diameter and thickness are suitable for mucoadhesive administration, the deviations varying within the limits of the size of the punch chosen for compression. The diameter obtained is ideal for this type of administration because the gum above the canine has a maximum size of 12-13 mm and a thickness greater than 4 mm would change compliance.

The tablets are white, uniform, without spots, without odor, slightly bitter taste diminished due to the mannitol added as a sweetener. The value of the friability test is according to the accepted parameters, a value of less than 1% for both proposed formulas (tab. IV).

All values of the mechanical strength parameter are within the corresponding limits, respectively between 30-90 N. Disintegration time is an extremely important parameter because the product must be released gradually in the oral mucosa (21). A rapid disintegration can lead to an ineffective antifungal. The longer the tablets stay in the mucous membranes, the longer the effect lasts and the longer the antifungal has time to act. The disintegration time of the proposed formulas is closely related to the amount of polymer used. In the case of the FI formula, which contains 40 mg carbopol, the disintegration time is 75 minutes and in the case of the FII formula, which contains 10 mg polymer, the disintegration time is 98 minutes. A smaller amount of polymer can soak with water forming a gel around the tablet (tab. IV). Thus, this gel slows down the disintegration of the tablet.

TABLE IV.
Physical properties of mucoadhesive tablets with miconazole nitrate

Formulation	Thickness (h) (mm)	Diameter (mm)	Surface area mm²	Hardness (N)	Friability %	Disintegration time (min)
FI	3.280	9.260	66.75	50.29	0.8965	75
FI-SD	±0.057	±0.174	±3.376	±7.601	±0.515	±4.393
FII	4.109	9.398	71.67	61.10	0.9100	98
FII-SD	±1.02	±0.981	±2.342	±10.245	±3.456	±5.601

Swelling index

The swelling index was calculated according to time (tab. V). When performing this test on sample for swelling, the weight changed with the swelling of the polymers in an aqueous solution. The swelling rate increased as the weight of these tablets increased in proportion to the rate of hydration up to two hours and then gradually decreased as a result of disintegration in the dissolution medium. It has been observed that total release is achieved when a lower concentration of polymer is added to the formula. The reason for this is the erosion of the gel layer in tablets containing smaller amounts of polymer. The higher the swelling index, the better the tablet will adhere to the oral mucosa, gradually releasing the amount of antifungal.

TABLE V.
Swelling index of mucoadhesive tablets

Formula	W1 initial (g)	W2 at 60 minutes (g)	W2 at 120 minutes (g)
FI			
	0.2390	0.3450	0.4700
	SI (%)	**0.4435**	0.9665
FII				0.2210	0.4490g	0.3200
	SI (%)	1.0316	0.4479

A swelling index at 60 min is 1.0316% for formula FII, which contains 10 mg polymer. The amount of polymer used in the FI formula swelled in the presence of water, greatly increasing its volume. The swelling index is 55% lower, 0.4435% in the formula

FI, which contains 40 mg polymer. For prolonged-release tablets, the swelling index needs to be greater than 1 and a higher concentration of the polymer leads to a longer soaking time with an aqueous solution. A film is needed that is made on the outside of the tablet when it is positioned at the level of the oral mucosa. The higher the swelling index, the more effective the mucoadhesive tablet can be. A large amount of polymer in formula FI, 40 mg, did not have enough surface contact with water to have higher SI results. The polymer, being a network-type structure, needs time and large contact surface with water to be able to soak water. The proposed mucoadhesive tablets have a small contact surface, 9 mm, and large amount of polymer does not allow interpenetration between the upper layers. A smaller amount of polymer, FII formula, evenly dispersed in the tablet may develop a higher SI.

In the case of SI at 120 minutes, the values differ a lot. For FI formula, the SI at 120 minutes is 0.9665%, about 50% more than the SI value at 60 minutes. In this case the large amount of carbopol had enough time to come into contact with water and to swell the polymer network. In the case of FII formula, the SI value at 120 minutes is 57% lower than the SI value at 60 minutes. If the polymer is in a lower concentration, it will be dispersed uniformly in 60 minutes, which conducts to a maximum water-soaked network structure. At 120 minutes the SI value of FII decreases because the gel formed around the tablet is gradually released.

CONCLUSIONS

Given that the antifungal active substance should be released gradually, FII formula with 4.5% carbopol may be proposed for future studies. The value of the swelling index and the disintegration time are important parameters for oral antifungal drugs in the form of mucoadhesive tablets. For FI formula, with 18% polymer, the swelling index is very small, being 132% lower than the FII formula with 4.5% polymer. Also, the disintegration time for FI formula is 30% shorter than the FII formula. The swelling index provides information about the ability of the new pharmaceutical form to stand on the oral mucosa. By disintegrating the tablet, the bioadhesive polymer in the aqueous medium forms a gel as it disintegrates. Thus, the longer this gel stays on the oral mucosa, the more active substance is gradually released from the pharmaceutical form and the contact time between the mucosa and the active substance will increase, which can provide a better action of the pharmaceutical product.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

THE STUDY AND DEVELOPMENT OF PERSONALIZED ORTHOTIC INSOLES THROUGH 3D PRINTING TECHNIQUE (Abstract): The human foot is the main connection of the body with the environment. It has a complex anatomical structure allowing different movements, such as gait, orthostatic position or running, on different surfaces, without any pain or injuries occurring. Upon it, there are many types of impact forces acting, therefore, the human foot has to absorb and dissipate these forces. The study of plantar pressures and their distribution across the foot aid in diagnosing and treating different pathologies. The plantar analysis helps in creating personalized tools for treating pathologies associated with the foot. **Objective:** This paper aimed to create a personalized insole, 3D printed, made out of flexible materials that would be fitted for this study's participant. **Material and methods:** The study consisted in collecting data from 12 subjects, with no known pathologies and performing the plantar pressure analysis, both static and dynamic analysis, then, modeling and printing the anatomical insole, fitted for the participant of the study. **Results:** The result is an anatomical insole, personalized, 3D printed, using flexible filament, with different thicknesses along the arches of the foot and different infill densities for unloading uneven plantar pressures across the foot. **Conclusions:** After all the stages of the study, a personalized insole was printed. The insole strictly follows the participant's foot anatomy, takes into account the distribution of plantar pressures across the foot and the deformities that were noticed as a result of the static and dynamic plantar analysis. **Keywords:** PLANTAR PRESSURE, INSOLE, 3D PRINTING, FLEXIBLE FILAMENT.

People spend the majority of their time in orthostatic position, walking or engaged in other types of physical activities. In this case, the feet and all the surfaces walked on are in direct contact. The plantar forces, forces that are acting upon the feet can sometimes have an uneven distribution. This uneven distribution can lead to a series of issues that can affect the general health of an individual (1).

Since the foot is the main surface of interaction during gait or every other physical activity, it is important to quickly identify any types of pathologies and deformities in their beginning phases so they could be either treated, prevented or corrected. One of the easiest, fastest and most reliable sources to do so could be considered the plantar pressure analysis (2).

Plantar pressure and its measurement offer information about foot and ankle function in orthostatic position and during

physical activities. The data obtained during the analysis of the important parameters involved in these movements are important in evaluating different pathologies and deformities that can affect the feet (1).

There is a great relationship between plantar pressure and the posture and balance of human bodies (3).

There are a lot of advantages in using this technique to assess different issues upon the foot, such as the usage of complex software able to perform and evaluate gait analysis, in both static and dynamic regimes, distribution of the plantar pressures across the feet, support areas, mass repartition, body posture. All the information can be easily saved and viewed in a database. The method in itself is easy to perform for both the specialist and the patient, fully objective and it allows modelling and creating personalized insoles fitted for each patient and their issues. Performing the analysis and taking the measurements are, as mentioned before, easy to obtain, the more difficult part is interpreting and analyzing the results obtained after the measurements (4).

Inadequate support of the feet can lead to numerous injuries in the short or long term. For better support, an anatomical insole can be one great solution. To create a personalized insole, the morphology should be perfectly adapted to the patient's feet. 3D printing of the insoles is the newest and best technique to create solutions for treating or preventing deformities, to ensure an even distribution of the pressure across the feet for better support and better comfort (5,6).

For designing shoes and the components of the shoes, such as the insoles, a detailed analysis of the feet is a key point, considering the different characteristics that every individual has. Given the fact that the feet of every individual are so different, it is important to understand and recognize certain patterns to obtain products that are both supportive and comfortable enough (7).

As stated before, the foot has an anatomical structure that is different for every person, therefore, when the plantar analysis is taken, a series of other parameters and measurements are important, such as: the length of the foot, width at different points, the height of the hallux and other toes, along with some information about the patient: age, sex, height, weight, shoe size (7,8).

MATERIAL AND METHODS

In this study, plantar analysis was performed on 12 participants. The plantar analysis was performed for both the static and dynamic regimes. The participants had no diagnosed pathologies but had different ages, heights, weights and shoe sizes.

The data was collected using the pressure plate Footwork (AMCUBE) and was visualized using the associated software.

The first step of the study was collecting data from the participants: age, sex, height, weight and shoe size. All this information is relevant because they change the way the plantar pressure is distributed across the foot (9, 10). The next step was performing the plantar analysis. For the static analysis, the subjects were asked to stand in a natural position for 10 seconds, their arms on the sides of the body, looking ahead, feet shoulder-width apart, both feet on the pressure plate. For the dynamic condition, subjects were asked to take two steps before striking the plate, right foot first, then in the same way for the left foot. Once the data was collected, it was visualized and organized for better understanding

in tables. The data that was looked at was mean and maximal pressure for both feet, in both conditions, the forces chart and mass distribution.

TABLE I.
General data collected from subjects

Subject	Sex	Age	Height (cm)	Weight (kg)	Shoe size (EU)
S1	F	48	165	69	40
S2	M	19	168	60	42
S3	F	20	160	48	38
S4	M	20	182	110	46.5
S5	M	23	181	85	40
S6	F	19	165	54	38
S7	M	20	177	68	41
S8	F	20	160	36	37
S9	F	19	158	48	38
S10	F	20	165	54	37
S11	M	21	180	86	44
S12	F	24	173	59	40

Fig. 1. Pictures taken during the scanning process.

To create the insole, out of the 12 analyses, only one was chosen given the different deformities and the pressure distribution that were noticed on the subject. Table I displays the plantar analysis for the chosen participant.

Once the plantar analysis was chosen, the next step was to create the model of the insole for printing. Firstly, Gensole was used. Gensole made possible the creation of a template for the insole with all the dimensional parameters of the participant's foot, along with certain modifications on the thickness and heights across the insole, in accordance with the foot's deformities,

TABLE II.

Plantar pressure for static and dynamic analysis.

Static					
Mean Pressure (kPa)		**Maximal Pressure (kPa)**		**Mass Repartition**	**Plantar Pressure**
Left Foot	Right Foot	Left Foot	Right Foot		56.53	51.66	151	125		

Dynamic					
Mean Pressure (kPa)		**Maximal Pressure (kPa)**		**Forces Chart**	**Plantar Pressure**
Left Foot	Right Foot	Left Foot	Right Foot		186	198	306	301		

Autodesk Fusion 360 was used to modify the specific zones according to the plantar pressures. For this, the 3D model previously obtained and the plantar pressure for the subject were overlaid to create a support for the transverse arch, as well as to mark zones for decreasing plantar pressures in areas where high values were observed.

For the printing of the model, Prusa Slicer was used to modify the local densities and geometries inside the insole.

In the last phase, the obtained personalized insole was printed using PRUSA i3 MK3. The used material was Filaflex, a flexible filament from Recreus with great proprieties for this type of application.

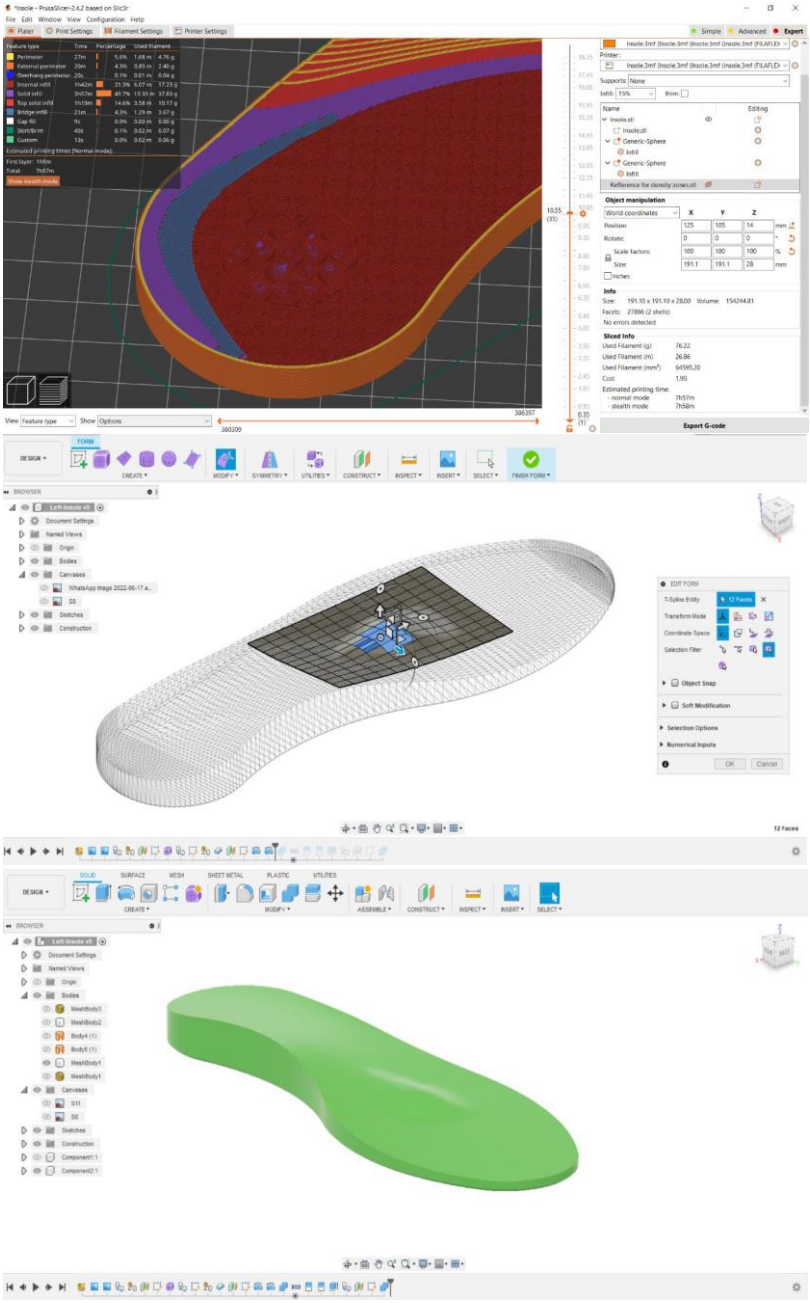

Fig. 2. Images during the modelling process.

RESULTS

After the 3D printing of the insole was performed, the result was a personalized insole, fitted for the study's participant. Different heights, thicknesses and heights were obtained across the plantar arches,

with the purpose of correction of pes cavus hindfoot valgus. Also, another advantage of the personalized insole is that it has zones of different infills that will serve as unloading areas of the high plantar pressures that were noticed in the first part of this study.

Fig. 3. Images of the personalized insole.

DISCUSSION

Over the last few years, the topic of personalized medicine, based on treating each patient individually and not the pathology itself has been presented as the future of the medical field. This type of approach has a series of advantages, such as the optimization of specific treatment schemes, better solutions fitted for every patient and lower final costs.

The study has presented such an application, a personalized solution for treating certain pathologies or for improving patients' comfort in their day-to-day life.

While many researchers have been working on creating customized insoles through various techniques and materials, the method presented in this paper has not been done before. Most of these papers were done regarding the study and comparison of thermoplastic elastomers. Mogan *et al.* (11) has conducted a series of studies regarding the proprieties that Filaflex has and the infill pattern impact on the mechanical proprieties of the final product and has concluded that this particular material has remarkable proprieties.

Zuniga *et al.*(12) developed a 3D printed insole, using two types of flexible filament, for comparison and evaluated plantar pressure distribution in walk trials. The development of the insole was, however, done using a 3D scanner along with the usage of Gensole and then printing the insoles. The authors have declared this method as being expensive. Also, their proposal was time-consuming compared to the method this paper presented.

Jandova *et al.* (8) have presented a study in which they developed a model of a 3D printed insole, which was based on specific parameters and characteristics of one of the three specific European feet, as they classified them, but their proposed method was not a personalized, custom made for patient application.

The method presented in this paper is a new method to design and create custom-made insoles to treat feet's pathologies or for better support and comfort. The combination of techniques that were used, such as the usage of just a pressure plate to identify the most affected areas across the feet, the usage of Gensole software to briefly design the template that was later used to shape and design different areas on the

insole in Autodesk Fusion 360 that would make the insole truly personalized and then the fabrication process, respectively 3D printing using a flexible material, Filaflex, a material with truly remarkable proprieties. All these methods combined have not been done before, making it possible to create a custom-made insole, perfectly personalized without needing a 3D foot scan, but only a pressure plate and the 3D printing machine.

CONCLUSIONS

This study's purpose was to create personalized insoles using flexible materials. Plantar analysis performed in both static and dynamic allowed for adequate data that was needed to use in the design and 3D printing of the insole. This technique has the potential of easing the technician's work through optimized and digitalized processes, with lower final costs and much quicker than using the standard methods, with better results for the patient as well.

CONFLICTS OF INTEREST AND FUNDING

Authors declare that there is no conflict of interests, and they received no funding for this study.

OBESITY AND ORTHOREXIA AMONG MEDICAL STUDENTS (Abstract). Lifestyle and eating behaviors change during the academic year. The aim of the study was to assess the lifestyle, eating behaviors, the presence of obesity, and orthorexia nervosa among students enrolled in medical studies in Romanian faculties. Data collected from 231 students gathered sociodemographic, medical, as well as anthropometric and psychological information. The statistical analyses were performed using IBM *Statistical Package for Social Sciences (SPSS)* for Windows, version 24.0 (SPSS Inc., Chicago, IL, USA). To identify the presence of orthorexia nervosa, the *Düsseldorf Orthorexia Scale* was used. The research identified that almost 70% of students have a normal status. Less than half of the students (42%, N = 97) consumed food supplements with the aim of improving cognitive performance during exam sessions. Students registered M = 3.02 ± 1.36 hours of physical activity per week. More than half of the students (53.7%, N = 124) estimated that they spent between 2 and 5 hours a day in front of screens. The collected data identified the presence of orthorexia nervosa in 6.1% of students, and 16.5% were evaluated as being at risk. More correlations were identified. Healthy lifestyles are difficult be maintained during academic years, and specific attention should be paid to dietary patterns and physical activity. Psychoeducation should be an important aspect of medical students' personal and professional development. **Keywords**: MEDICAL STUDENTS, HEALTHY LIFESTYLE, EATING BEHAVIOURS, OBESITY, ORTHOREXIA NERVOSA.

The 21st century is facing a global obesity epidemic, and this obesity crisis has become one of the greatest challenges of our time with widespread recognition as an important global public health issue. The prevalence of obesity has skyrocketed in these early years of the 21st century, affecting populations in both developed and developing countries, and this increase has rapidly become a public health problem (1).

Obesity entails a significant economic burden on individuals and their families, but also on health systems and society in general, both through direct healthcare costs for treating obesity-related complications and indirect costs through reduced productivity and job performance. It is

important that strategies to address obesity involve individuals and communities as well as health care providers and policy-makers and include creating supportive environments for at-risk populations, promoting healthy lifestyle habits, obesity prevention strategies, and improving access to health care treatment (2).

Obesity profoundly impacts health and is associated with numerous health risks and chronic non-communicable diseases. Thus, it is a risk factor for developing insulin resistance and type 2 diabetes, as excess adipose tissue influences the body's ability to regulate blood glucose levels. Visceral fat causes the accumulation of atheromatous plaques, narrowing arteries and restricting blood flow, thus increasing the risk of cardiovascular disease, high blood pressure and stroke. Certain cancers are thought to be closely linked to obesity, including breast, colorectal, ovarian, liver, kidney, and pancreatic cancers. Obesity also leads to the development of respiratory problems such as sleep apnea, hypoventilation syndrome, and asthma. Because of the extra stress on the bone system and joints, people with obesity are at risk of developing osteoarthritis and back pain. Mental health is influenced by obesity, as people with obesity have higher rates of depression and anxiety due to social stigma and compromised body image.

According to the World Obesity Federation, it is estimated that nearly 30% of men and women will develop obesity by 2030 (1). Furthermore, the Eurostat report for 2019 concluded that in Europe, 53% of adults are overweight or obese, depending on BMI, and the percentage of obesity is directly proportional to age, except for people over 75 (3).

In terms of the proportion of young adults who are obese, this varies from country to country and according to gender; thus, the European average of obese people in the 18–24 age group was, according to Eurostat, 25% in 2019. The lowest value was recorded in Italy (18%), and the highest value, 31%, was recorded in Hungary. Romania recorded 25.4%, a percentage close to the European average (4).

There are several factors that can affect the rise of obesity among students. Among them is changing eating habits by adopting eating patterns that are mainly characterized by frequent consumption of high-calorie foods, fast food, and snacks instead of meals, as well as sweetened carbonated drinks, all of which contribute to weight gain and obesity. Restricting access to nutritious food or skipping breakfast (5) may also be contributing factors to obesity.

The goal of the present study is to investigate the presence of eating behaviors, obesity, and orthorexia nervosa among medical students in Romania, and the factors that influence them. There is a gap in the data concerning obesity among medical students in Romania, so the research focused on identifying the underweight, normal, and overweight students enrolled in medical studies, but also, considering the specialization - medical studies – the research team took into consideration that students enrolled in medical studies should be more focused on eating healthy and maintaining a good physical and mental life (6). That is why the investigation also took orthorexia nervosa as a variable. This is defined as an obsession with healthy eating accompanied by restrictive behaviors, sometimes being associated with malnourishment, loss of relationships, and poor quality of life (6).

MATERIALS AND METHODS

Participants and data collection

The study was conducted between April and May 2023 among students from the "Grigore T. Popa" University of Medicine and Pharmacy of Iasi. The participants were informed about the purpose of the study, about the confidentiality of the data, and that they could withdraw from the study whenever they wanted, without consequences. The inclusion criteria were being students of the medical field and filling out the questionnaire before the deadline. The exclusion criteria were questionnaires that were incomplete or submitted after the deadline. Finally, 231 questionnaires were included in the research.

The online questionnaire was created using the Google Forms application (Alphabet, Mountain View, CA, USA).

The first part of the questionnaire gathered socio-demographic information (like age, gender, living environment, year of study, the faculty where they study, and if they have employee status), medical information (if they or another family member suffers from chronic diseases and follows any treatment for their disease), and anthropometric data (height, weight, abdominal circumference, following a diet).

The second part of the questionnaire includes several questions grouped by various lifestyle components and factors that can influence lifestyle:

- substance consumption (tobacco, alcohol, psychoactive substances, or food supplements),
- the perceived influence of emotional factors on food (frequently consumed foods and changes in appetite during states of nervousness, stress, boredom, eating without feeling hungry, the level of consciousness felt while chewing food etc.),
- the influence of family income on eating behavior (the source where the money comes from, the percentage of income invested in buying food, proximity to restaurants, supermarkets, agri-food markets)
- the behavior related to the carried out physical activity,
- sleep-related behavior and time spent in front of screens,
- acquired food patterns and the frequency of food and beverages consumed.

The final part of the questionnaire includes one instrument, which refers to assessing and screening orthorexia nervosa: Düsseldorf Orthorexia Scale. This instrument was developed in 2015 by Barthels *et al.* and consists of 10 items with proven reliability, ranging from satisfactory to good, with an internal consistency of $\alpha = 0.84$. This scale is based on a four-level scoring system from "this does not apply to me (1)" to "this applies to me" (4), with scores ranging from 10 to 40 points (7, 8).

Statistical analyses

The statistical analyses were performed using IBM *Statistical Package for Social Sciences* (*SPSS*) for Windows, version 24.0 (SPSS Inc., Chicago, IL, USA). The results for descriptive statistics were expressed as means and standard deviations (SD). The normality of the data distribution was assessed by using the Kolmogorov-Smirnoff test. Given the fact that all data are not normally distributed, bivariate analysis will be performed and non-parametric tests will be applied. To assess comparative results considering gender, employee status, and chronic disease diagnosis, the Mann-Whitney test was performed.

Comparative results considering sex, living environment, and changes in appetite depending on the emotional state following

a diet, were assessed by using the Kruskal-Wallis H test to determine if there were statistically significant differences between more than two groups of an independent variable on a continuous or ordinal dependent variable.

The Spearman correlation was used to test the relationship between variables. A p-value < 0.05 was considered statistically significant.

Ethical approval

The study was conducted in accordance with the Declaration of Helsinki, and the protocol was approved by the Ethical Committee of the University of Oradea, No. CEFMF/3, March 16th , 2023.

RESULTS

Socio-demographic, medical, and anthropometric data

Sociodemographic data were gathered, along with household-related information and medical information. The average age of participants was M = 23.61 ± 6.71. More than half of the students lived in a rented apartment (56.3%, N = 130), while the rest lived at home with their parents (16.5%, N = 38), or in a student dormitory (27.3%, N = 63).

Most of the participants (88.7%, N = 205) and their family members (70.1%, N = 162) did not suffer from chronic diseases, and a very small part took medication for chronic diseases (8.2%, N = 19). Additional information about anthropometric and medical data is presented in first table.

TABLE I.

Socio-demographic data[1]

Socio-demographic characteristics	M±S.D and %
Abdominal circumference	73.66 ± 15.15
Nutritional status	
Underweight	24 (10.4%)
Normal status	161 (69.7%)
Overweight	37 (16.0%)
Obesity	9 (3.9%)
Following a diet	
Yes, it was recommended to me by a health professional	9 (3.9%)
Yes, I chose it personally	31 (13.4%)
Yes, I tried but failed	24 (10.4%)
No, I didn't follow a diet	167 (72.3%)

[1]Means and standard deviations (M±D), frequency and percentages (%)

Lifestyle components and factors that can influence lifestyle

Substance consumption

The results of the study showed that more than half of the participants had never smoked (64.9%, N = 150), and a small part smoked daily (14.7%, N = 34) or occasionally (19.5%, N = 45). Moreover, more than half of the participants' family members had never smoked (59.7%, N = 138), while more than a third smoked daily (32.5%, N = 75).

Less than half of the students (42%, N = 97) consumed food supplements with the aim of improving cognitive perfor-

mance during exam sessions. Regarding the consumption of other substances, detailed results are presented in the table below.

TABLE II.

Substance consumption[1]

Substances	N, %
Alcohol	
never	52 (22.5%)
sometimes	173 (74.9%)
often	6 (2.6%)
daily	0
Psychoactive substances	
never	217 (93.9%)
sometimes	12 (5.2%)
often	1 (0.4%)
daily	1 (0.4%)

[1]Frequency and percentages (%)

The perceived influence of emotional factors on food

In terms of emotional eating, half of students (50.6%, N = 117) admitted that they ate more when they felt stressed, nervous, or bored, the most consumed foods like sweet puff pastry such as Fornetti products, doughnuts, strudel, etc. (20.3%, N = 47), cream cakes (18.6%, N = 43), salted foods - such as sticks, pretzels, breadsticks (18.6%, N = 43), or salted puff pastry (7.8%, N = 18), and very few (3.9%, N = 9) were those who consumed more fruits during these tense periods.

However, less than half of the participants admitted that their eating pattern had changed largely (32.5%, N = 75) or to a great extent (14.3%, N = 33) after admission to college. Additionally, less than half of the students (44.6%, N = 103) rarely ate without being hungry, and most of them (71.9%, N = 166) were moderately aware when chewing food.

In addition, more than a third of the participants (39.8%, N = 92) said that it was difficult for them to leave food on the plate, only when it came to their favorite food.

The influence of family income on eating behavior

More than half of the students had a source of income from their parents (69.3%, N = 160), with a few having a stable job (17.7%, N = 41). Regarding the income allocated to buy food, less than half of the students (42.4%, N = 98) said that they spent between 25 and 50% of their income on food. Similarly, less than half of the students (43.3%, N = 100) largely considered that the income they had was enough to ensure their daily lives.

Most students lived in areas close to supermarkets (73.2%, N = 169) or neighborhood stores (14.7%, N = 34), and fewer lived in the areas of agri-food markets (4.8%, N = 11) or fast-food stores (3.0%, N =7).

The behavior related to the physical activity carried out

Students performed an average of **M = 3.02 ± 1.36** hours of physical activity per week. However, 48.1% of them (N = 111) declared that they rarely conducted physical activities, and a third of them (33.3%, N = 77) conducted physical activities often. The most practiced physical activities were walking (57.1%, N = 132), fitness activities in the gym (22.1%, N = 51), jogging (4.8%, N = 11), or others (5.6%, N = 13).

Sleep-related behavior and time spent in front of screens

More than three-quarters of the students (75.8%, N = 175) declared that they slept between 6 and 8 hours a night. Most students (91.8%, N = 212) declared that they

never woke up at night to eat, with very few being those who did this sometimes (7.4%, N = 17). Regarding sleep during the day, more than half of the participants (57.6%, N = 133) declared that they rarely slept during the day.

Additionally, more than half of the students (53.7%, N = 124) estimated that they spent between 2 and 5 hours a day in front of screens, be it a TV, smartphone, tablet, video game, or laptop.

Acquired food patterns / frequency of food and beverages consumed

More than half of the students (63.2%, N = 146) cooked or ate cooked food daily. Regarding the main meals of the day, less than half of the participants (43.3%, N = 100) served breakfast daily, with lunch being the most consumed meal of the day (35.5%, N = 82).

Sometimes, the main meals were replaced with pretzel-type snacks, sweets, and puff pastry by the majority of students (75.3%, N = 174). Moreover, more than a third of the participants (38.1%, N = 88) declared that they rarely ate with family members.

Most students (67.5%, N = 156) ate fast food only 1-2 times a month. More than half of the participants (61.5%, N = 142) had never consumed sugar-free carbonated drinks. More than half of the students consumed fish only 1-2 times a month (55.0%, N = 127), fruits 2-4 times a week (56.3%, N = 130), and vegetables a few times a week (55.4%, N = 128). More than a third of the participants (39.0%, N = 90) had never consumed cereal products. Other detailed results are presented in third table.

Less than half of the students (41.6%, N = 96) often read the food label, with the most sought-after checked components being sugar (24.7%, N = 57), calories (24.2%, N = 56), or additives (13.0%, N = 30).

TABLE III.

Frequency of food consumed[1]

Food	N, %
Meat (chicken, beef, pork)	
daily	45 (19.5%)
5-6 times a week	40 (17.3%)
3-4 times a week	92 (39.8%)
1-2 times a week	46 (19.9%)
never	8 (3.5%)
Eggs	
daily	18 (7.8%)
5-6 times a week	12 (5.2%)
3-4 times a week	40 (17.3%)
1-2 times a week	152 (65.8%)
never	9 (3.9%)
Milk/dairy and cheese	
daily	58 (25.1%)
5-6 times a week	41 (17.7%)
3-4 times a week	56 (24.2%)
1-2 times a week	60 (26.0%)
never	8 (3.5%)
Fried food	
daily	11 (4.8%)
5-6 times a week	22 (9.5%)
3-4 times a week	67 (29.0%)
1-2 times a week	111 (48.1%)
never	20 (8.7%)

[1]Number of answers (N) and percentage (%)

Assessing and screening of orthorexia nervosa

Cronbach's alpha of 0.868 showed that the scale had a high level of internal consistency. The total score for the *Düsseldorf Orthorexia Scale* was on average M = 19.56 ± 6.08, the scores ranging from 10 (4.8%, N = 11) to 39 (0.4%, N = 1).

A small part of the students had a high

score on this scale, which would indicate the presence of orthorexia nervosa. No risk of developing ON was observed in 77.5% of the students in the present study, as shown in table IV.

TABLE IV.
Prevalence of ON among students[1]

DOS	N, %
Presence of ON (≥ 30)	14 (6.1%)
At risk of ON (25–29)	38 (16.5%)
No risk of ON (< 25)	179 (77.5%)

[1]Number of answers (N) and percentage (%)

Comparative and correlational analysis

Comparative analysis showed that students who had employee status (Mdn = 21.00) had a higher score on the Orthorexia Scale, being more fixated on health-conscious eating behavior ($p = 0.007$, $U = 2905.50$, $z = -2.720$) than students who were not employed (Mdn = 18.00). Similarly, the results of the Mann-Whitney test ($U = 1430.00$, $z = -2.055$, $p = 0.040$) showed that underweight students had a lower score on the Orthorexia Scale (Mdn = 17.00) than normal-weight students (Mdn = 18.00). No gender difference was identified.

The Kruskal-Wallis H test revealed that there were statistically significant differences in total Orthorexia Scale score among groups with different levels of physical activity: those who practiced physical activity daily ($n = 34$), those who practiced physical activity often ($n = 77$), those who practiced sports rarely ($n = 111$), or those who never did such activities ($n = 9$); $\chi^2(3) = 15.855$, $p = 0.001$. The Mann-Whitney U post hoc analysis ($p = 0.009$, $U = 65.50$, $z = -2.621$) showed that participants who had never done sports had a much lower score on the Orthorexia Scale (Mdn = 14.00), as opposed to those who did sports daily (Mdn = 22.00). Additionally, the Mann-Whitney analysis ($p = 0.021$, $U = 3428.00$, $z = -2.310$) showed that those who did sports often (Mdn = 18.00) had a higher score on the Orthorexia Scale, in contrast to those who rarely did sports (Mdn =17.00).

Comparative analysis ($p < 0.001$, $U = 1366.50$, $z = -4.230$) showed that students who smoked daily (Mdn = 14.50) had a lower score on the Orthorexia Scale than students who had never smoked (Mdn = 19.00). Similarly, students who never drank alcohol (Mdn = 21.00) had a higher score on the Orthorexia Scale than students who drank alcohol often (Mdn = 15.00) ($p < 0.007$, $U = 50.50$, $z = -2.701$).

Significant differences ($p = 0.011$, $U = 168.50$, $z = -2.534$) resulted between students who were not at all conscious when chewing food, being rather attentive to their laptop or phone (Mdn = 17.00) and those who were extremely conscious when eating, the latter having a higher score on the Orthorexia Scale (Mdn = 22.00).

Our results showed that there was a positive correlation between body mass index and abdominal circumference. Thus**,** we identified that the higher the abdominal circumference value of the students, the higher the BMI ($r = 0.61$, $p < 0.01$).

A strong negative correlation was identified between the consumption of tobacco and the frequency of consumption of carbonated drinks ($r = -0.27$, $p < 0.001$), in the sense that the more the students smoked, the more they tended to consume fewer soft drinks. Tobacco consumption was also negatively correlated with meat consumption, so that the more the students smoked, the more they tended to decrease the frequency of meat consumption ($r = -0.17$, $p = 0.09$).

Positive correlations were identified between the frequency of tobacco consumption and the frequency of alcohol consumption ($r = 0.36$, $p < 0.001$), respectively of

the consumption of psychoactive substances ($r = 0.28$, $p < 0.001$), in the sense that the more the students smoked, the more alcohol and psychoactive substances they consumed.

A negative correlation was identified between the level of self-consciousness that students had when chewing food and using tobacco. Thus, the more the students were aware of the way they ate, the less they tended to smoke ($r = -0.20$, $p = 0.002$). Significant results regarding various items and the score obtained on the Orthorexia Scale are presented in table V.

TABLE V.

Correlation analysis results

Variables	DOS
BMI	r = 0.187**, p = 0.004
Tobacco consumption	r = -0.254**, p = 0.000
Alcohol consumption	r = -0.270**, p = 0.000
How conscious are you when you chew your food?	r = -0.158*, p = 0.016
Performing physical activity	r = 0.255**, p = 0.000
Frequency of consumption of eggs	r = -0.189**, p = 0.004
Frequency of consumption of meat	r = 0.144**, p = 0.029
Frequency of consumption of fish	r = -0.138*, p =0.036
Frequency of consumption of cereal products	r = -0.194**, p = 0.003

* $p < 0.05$; ** $p < 0.001$.

DISCUSSION

Maintaining a healthy lifestyle throughout adulthood is crucial for ensuring a healthy life in old age. Academic years are very challenging because, due to the chaotic schedule, the increased fast-foot intake and less time to practice sports could lead to a lower quality of physical and mental life.

The present study identified that medical students were at some risk: underweight and overweight was registered in 30% of students, and the presence of orthorexia nervosa or the risk of developing it was identified in 22.5% of respondents. Orthorexia nervosa was identified in students, and results from the scientific literature revealed that it was linked to the cognitive domains affecting attention, verbal long-term memory, visuospatial functioning, and executive functioning (9, 10). For example, orthorexia nervosa was measured among undergraduate medical students, and the prevalence was between 21.1% and 69.93% (11). Other research conducted on students revealed that those studying health-related majors were characterized by more pronounced symptoms of orthorexia nervosa with evidently more pronounced symptoms among physicians, dieticians and athlete students (12).

We found that students with higher scores on orthorexia nervosa ate eggs and meat more frequently, avoided tobacco and alcohol, and had a higher level of physical activity compared to students with no orthorexia nervosa. The research identified no significant results between male and female students, with similar data being registered by other international studies (13).

The frequency at which physical activity is performed is an important indicator that has been identified in other studies. During the undergraduate period, the phys-

ical activity schedule is rather individual; there are no PE classes or other extracurricular activities organized systematically, and free time is rather spent watching TV or engaging in rather sedentary activities such as video games, or computer use (14, 15).

Moreover, during this period, parental involvements in healthy food choices and physical activity decreases, as only a small proportion of students still live with their parents. In addition, academic schedules are busy, further limiting contact between parents and students.

Students from lower socioeconomic backgrounds may face decreased access to nutritious food (16) as well as to the opportunity to attend gyms, which increases the risk of developing obesity. Economic constraints can lead to the consumption of cheap but energy-dense foods with low nutritional value.

Environmental factors such as the availability of unhealthy food options on or around campus and food marketing to students, coupled with the lack of safe and financially accessible spaces for physical activity, can influence students' weight (17, 18).

Last but not least, genetic predispositions influence an individual's susceptibility to weight gain and obesity. Hormonal imbalances, some medical conditions, and some pharmaceuticals can also contribute to weight-related problems among students (19).

It is important to note that these factors are bidirectional, demonstrating once again the complexity of the causes of obesity among students. Therefore, obesity needs to be addressed in a multidisciplinary manner and involve individuals, their families and friends, the university environment, the community, and policymakers to promote healthy eating, physical activity, and a supportive environment for students.

In terms of obesity among medical students, there are a few factors that differ from the general student population: the high level of stress and workload faced by medical students due to the demanding nature of medical studies, the long internship and lecture hours, and the intense workload. Poor stress management can lead to emotional eating, unhealthy food choices, and a lack of time for physical activity, potentially contributing to weight gain and obesity.

Medical students' irregular schedules, prompted by rigorous schedules and demanding medical school clinical rotations, can disrupt mealtimes and sleep patterns, and this irregularity can make it difficult to maintain a healthy eating routine and engage in regular physical activity, thereby increasing the risk of weight gain, especially through a preference for fast food options with low nutritional value.

Although medical students are knowledgeable about health, including the risks associated with obesity, the pressures and demands of medical school can lead to neglecting personal health and prioritizing academic activities over their own health.

Medical schools are characterized by a competitive environment and peer pressure, and consequently, long study hours and neglecting personal wellness to achieve academic success can contribute to stress eating, sedentary behaviors, and weight gain.

The lack of clinical exposure, which is prevalent in the early years of medical school, further contributes to the development of sedentary behavior as students spend more time in classes than in the clin-

ical environment.

Obesity has a significant impact on a person's quality of life at different stages of life. At the psychological level, negative body image, depression, and social stigma are commonly experienced by people with obesity, negatively affecting their social relationships, couple relationships, and quality of life (20, 21). At the same time, as their social life is also affected, they enter a vicious circle in which the person with obesity finds it increasingly difficult to form or maintain social relationships and adopts a social isolation that will further lower their self-esteem and deepen their depression. Economically, a person with obesity may face reduced productivity at work and increased medical expenses.

CONCLUSIONS

Addressing obesity among medical students requires specific attention and support from medical schools and institutions. Implementing programmes that promote healthy lifestyle behaviors, providing access to affordable nutritious food on campus, creating opportunities for physical activity, and offering free stress management support services could help medical students adopt healthy lifestyle habits despite the academic challenges they face.

COMPARATIVE MORPHOLOGIC AND CHEMICAL PRELIMINARY ASSESSMENT OF THREE ROMANIAN *AGASTACHE* SPECIES (Abstract): Phenolic compounds, such as flavonoids and phenolic acids, are classified as secondary metabolites in plants. The increasing interest in utilizing these components in traditional medicine for the prevention or treatment of diverse pathologies based on their antioxidant properties. **The objectives** of this study were to identify the microscopic characteristics and to quantify the levels of total phenolics and flavonoids of three different *Agastache* species: *A. foeniculum*, *A. mexicana*, and *A. urticifolia*. **Material and methods:** Microscopy followed 10th European Pharmacopoeia (Ph. Eur.) provision regarding the evaluation of plant products. The quantification of phenolic content was conducted using the Folin-Ciocalteu method, while the determination of total flavonoids was conducted using the aluminum chloride and sodium nitrate method. **Results**: Microscopic features showed similar structures for leaves and flowers. Differences were given by the density of stomata and glandular or surface trichomes. The total phenolic content of the extracts varied from 213 to 642 mg % and the maximum was determined for *A. foeniculum*. Also, the measured total flavonoid content was found to be between 29.4 mg % and 58 mg %, the same sample having the highest amount. **Conclusions:** The methanolic extracts of this plant exhibits a notable concentration of phenolic and flavonoid compounds, suggesting its potential as a therapeutic agent for various diseases. However, further investigation is required to fully understand its efficacy and safety profile. **Keywords**: MICROSCOPY, TOTAL PHENOLS, TOTAL FLAVONOID CONTENT.

The taxonomic classification of the plant genus *Agastache* situates it within the botanical family *Lamiaceae*, encompassing a collective assemblage of 22 distinct species of enduring aromatic herbs that possess notable medicinal characteristics. The *Agastache* genus is known for its notable prevalence of phenylpropanoid and terpenoid specialized metabolites, a trait frequently observed within the *Lamiaceae* botanical family. One classification of chemical compounds encompasses flavonoids, free phenolic acids and depsides, alongside lignans, while the other significant classification is based on terpenoids, which can be discerned as both volatile and nonvolatile fractions (1, 2).

Agastache foeniculum, known by vari-

ous common names such as anise hyssop, blue giant hyssop, fragrant giant hyssop, or the lavender giant hyssop, is indigenous to the north-central and northern regions of North America. It possesses a chemical composition that includes volatile oils, phenolic compounds (specifically phenolic acids and flavonoids), as well as derived flavonoids, alcohols, cinnamic aldehydes, terpenoids, and other similar substances, with concentrations ranging from 0.9 g % to 1.8 g % (3, 4, 5). Various components of the plant are utilized for the management of cardiovascular, nervous system, and gastrointestinal ailments, in addition to their application in the treatment of common colds, fevers, and bodily discomfort. Additionally, the plant exhibits antivomitive, antibacterial, and antifungal properties (6, 7).

Agastache mexicana, a vascular plant indigenous to Mexico, exhibits the characteristic morphology of the *Lamiaceae* family, including opposite, petiolate leaves, a four-angled stem, and abundant trichomes. This plant has been traditionally recognized in Asia for its culinary and medicinal properties. Research findings have demonstrated that certain components of the plant exhibit properties associated with antioxidant, antifungal, anti-inflammatory, antiobesity, and anti-photoaging effects (8, 9).

Agastache urticifolia is a perennial plant that is strongly aromatic, and it is known by wo varieties of the species var. *urticifolia* and var. *glaucifolia*, however, only native populations of the former exist in Utah mountain ranges (10, 11). Though native to the Intermountain West (USA), this species has been cultivated throughout the world and even used for ethnobotanical practices in Bangladesh (12, 13).

The majority of the published studies primarily concentrate on the analysis of essential oils. Additionally, a considerable number of scholarly articles have been published documenting the process of isolating and comprehending the molecular structure of diverse phytochemical compounds (14, 15, 16, 17).

The aim of this study was to conduct a comparative analysis of three *Agastache* species, namely *A. foeniculum*, *A. mexicana*, and *A. urticifolia*, following microscopic features of the leaves and flowers and the total polyphenolic and flavonoid compounds obtained from methanolic extracts.

MATERIAL AND METHODS

Plant material and reagents: Agastache foeniculum (AG1) comes from Cluj-Napoca 46°46′42.24″ N, 23°37′01.92″ E, *Agastache foeniculum* (AG2) and *Agastache mexicana* (AGM) were harvested from Brașov (Dacia Plant), 45°39′ N 25°36′E, while *Agastache urticifolia* (AGU) was harvested from the Republic of Moldova, Chisinau, 47°01′0″N 28°52′0″E. All chemicals and reagents used for extraction and characterization were of analytical grade, provided by Sigma Aldrich Chemical Co. (Germany) and were used without further purification.

For each of the three species, the air-dried plants (5 g) were pulverized into a fine powder using a mill. The resulting powder was then subjected to extraction using 50 mL of 50% methanol (V/V) at 70°C for 1 hour under reflux. Following the cooling process, the extracts underwent filtration. The isolated products were subsequently rinsed with a solution consisting of 10 mL of 50% (V/V) methanol. The resulting filtrates were combined in a volumetric flask and further diluted to a final volume of 100 mL using the same solvent. A portion of 80 mL was taken from each extract and was concentrated using a rotary

evaporator (Buchi R 210, Switzerland) in order to eliminate the solvent. The residues were subjected to a drying process and subsequently stored at a temperature of 4°C in order to facilitate further analysis.

Microscopic investigation: The powdered plant material was clarified with chloralhydrate (80% in water) directly on the microscopic plate. All steps were according to the indications of Ph. Eur. 10 (18). The visualization and photography of the observed elements were realized with an Optika (WF10X-11MM) microscope with built-in camera (Canon PS A450).

Determination of total phenolic content: The determination of the total phenolic content of each extract of *Agastache* was conducted using the Folin-Ciocalteu reagent, following the method proposed by Singleton and Rossi (19), with gallic acid serving as the standard. A standard curve was generated by determining the concentrations of gallic acid within the range of 3-6 µg/mL. The outcomes were quantified in terms of gallic acid equivalents (GAE), specifically measured as milligrams of gallic acid per 100 g dry plant material (20, 21).

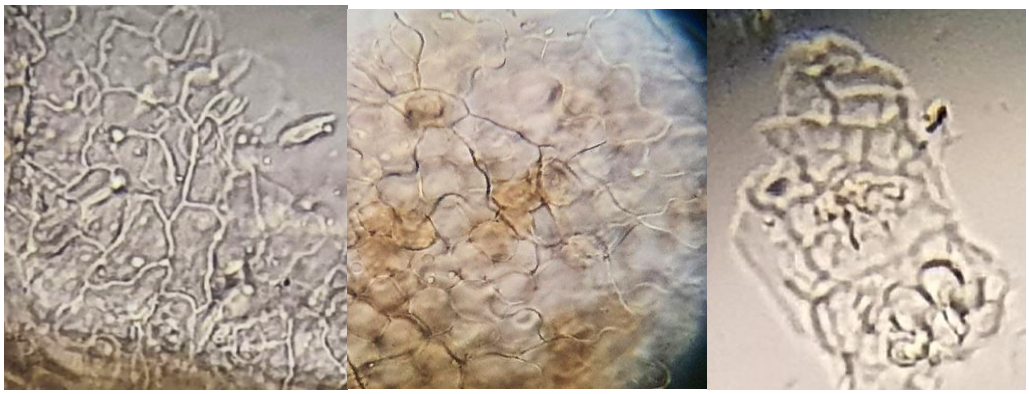
Determination of flavonoid content: The quantification of the overall flavonoid content was conducted using a colorimetric assay as previously (20, 21). The quantification of the total flavonoid content in the extract was denoted as rutoside (mg rutoside (RUE)/100 g dry plant product).

For all determinations, samples were analyzed in triplicate.

RESULTS AND DISCUSSION

Morphologic characterization

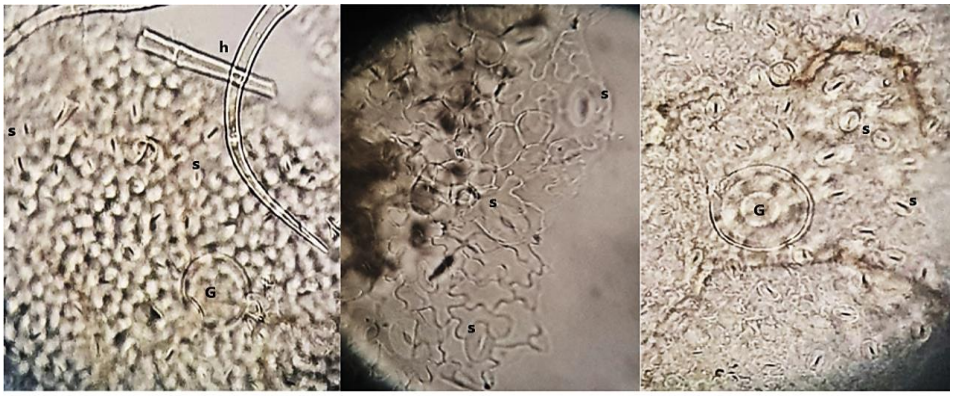
Our observations indicated the presence of common tissue (upper and lower epidermis, stomata, vascular bundles) and similar structures (octocellular glandular trichomes and surface hairs) with taxonomic relevance in all investigated samples, as indicated in fig 1-3. Such microscopic characteristics prove that the investigated species belong to Lamiaceae family (22).



Agastache foeniculum *Agastache mexicana* *Agastache urticifolia*

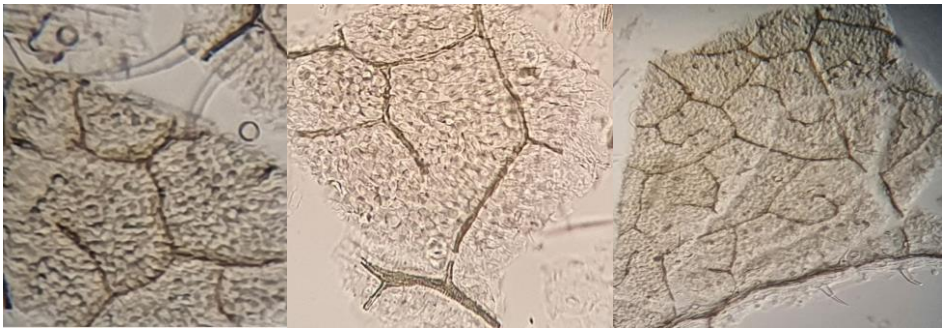
Fig. 1. Front view of upper epidermis (adaxial surface) showing elongated cells with thicker and almost straight walls in the investigated *Agastache* samples

Numerous small stomata were present in *A. foeniculum* and *A. urticifolia* abaxial surface, whereas bigger and fewer stomata were noted in the *A. mexicana* sample (fig. 2).



Agastache foeniculum *Agastache mexicana* *Agastache urticifolia*

Fig. 2. Front view of lower epidermis showing cells with thin and wavy walls: s - stomata, G - octocellular glandular trichomes, h - pluricellular surface trichomes



Agastache foeniculum *Agastache mexicana* *Agastache urticifolia*

Fig. 3. Front view of leaf mesophyll with vascular bundles (vascular network is represented by the dark brown veins

For all three species, the microscopic examination highlighted the presence of numerous short, single cell surface hairs, monocellular head and sessile octocellular glands denser on the flower epidermis and on the abaxial surface of the leaves (fig. 4). Moreover, long pluricellular (3-5 cells) surface hairs were noted in *A. foeniculum* and *A. urticifolia*, but not as frequent as the short trichomes.

Although the information regarding leaf and flower morphology of *Agastache* species is scarce, similar to our results but using scanning electron microscopy previous researchers have revealed that the upper surface of the leaf comprises both simple non-glandular and glandular (capitate and subsessile) trichomes, which possess the capability to yield essential oil through extraction processes. The essential oil samples of *A. urticifolia* from cultivated (Russia) and native (Oregon, USA) populations, which have been previously examined, have demonstrated a predominant composi-

tion of volatile compounds, namely limonene, menthone, and pulegone. It is worth noting that these compounds exist as enantiomers in the natural environment (23, 24).

In our samples, pollen grains were visible in two of the investigated samples (fig. 5).

Secondary metabolites quantification

Total phenols content varied between 213 ± 3.21 mg% to 642 ± 3.12 mg%, *Agastache foeniculum* samples being the richest in such metabolites. Table I represents the analytical data for phenolics and total flavonoid content of the methanolic extract of the three *Agastache* species.

Plant extracts' total phenolic content has been linked to antioxidant activity due to their redox properties, which allow them to function as reducing agents, hydrogen donors, and singlet oxygen quenchers. For our samples, the most promising samples seem both *A. foeniculum* species, the best being AG2, the sample harvested from Brasov. The lowest content was detected for AGM, a species which originates from

Mexico and most probably the environmental conditions do not offer proper conditions for a better biosynthetic capacity of the plants grown in our country. Similar results were obtained by Balanescu *et al.* for ultrasonicated ethanolic and methanolic extracts obtained from *A. foeniculum* cultivated in Romania (25). A better extractability was noted for the methanolic extracts as compared to ethanolic extracts.

TABLE I.
Total phenolic content for the three species of *Agastache*

Sample name	Total polyphenols (mg GAE %)	Total flavonoids content (mg RUE %)
AG1	455 ± 2.02	53 ± 1.78
AG2	642 ± 3.12	58 ± 2.43
AGM	213 ± 3.21	29.4 ± 1.08
AGU	396 ± 2.01	49.9 ± 1.11

In regard to the flavonoid content, the same sample, AG2, had the richest content of flavones, whereas *A. mexicana* registered the lowest amount. It was notable that the same variability was registered for flavonoids and total phenolic content. Taking into account that the extracted amounts were high, we can state that 50 % methanol was a good solvent for these classes of metabolites.

Currently, there are few studies pertaining to the phytochemical compositions and components found in *Agastache* species. Furthermore, a comprehensive comparative study is necessary in order to thoroughly understand the distinctions between these species. Furthermore, the characterization of primary and secondary metabolic compounds in *Agastache* species remains incomplete in terms of comparative study, with particular emphasis on the influence of flowering stage and cultivation time. Additionally, there is a lack of quantitative research that has investigated the alterations in composition throughout various stages of flowering, as well as the significance of each stage within the flowering process (7, 9, 14, 17).

CONCLUSIONS

The utilization of herbal products for the treatment of diseases has garnered significant attention in recent years. This is primarily attributed to the wide range of phytometabolic components found in these products, which possess diverse chemical structures and exhibit various biological activities. The utilization of *Agastache* species in traditional medicine for the treatment of diverse ailments has been prevalent for an extended period of time.

Plants exhibit a substantial presence of polyphenols and flavonoids which was demonstrated in this paper for *Agastache foeniculum*, *Agastache mexicana* and *Agastache urticifolia*, which contribute to their robust antioxidant capabilities. Consequently, these properties enable plants to engage in diverse defensive mechanisms and combat diseases effectively. Phenolic compounds are regarded as significant constituents of plants due to the presence of one or more hydroxyl groups on their aromatic ring, making them secondary metab-

olites. Due to the absence of adverse effects on human health, there has been a rise in the utilization of plant species with elevated levels of phenolic compounds within the food industry, with the objective of enhancing the overall quality of food products.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest.

Mihaela-Magdalena Flutur and Denisa Marin-Batir, had equal contribution and should be regarded as main authors of the manuscript.

TRANSLATION, RELIABILITY AND VALIDITY OF THE ROUMANIAN VERSION OF ORTHOGNATHIC QUALITY OF LIFE QUESTIONNAIRE (OQLQ) (Abstract): Orthognathic surgery is an essential treatment for addressing dentofacial anomalies which significantly affect the psychological and social aspects of a patient's life. This study aimed to translate, adapt, and validate the OQLQ questionnaire into Romanian language, specifically designed to measure the quality of life of individuals with dentofacial anomalies. **Materials and methods**: The validation process of the OQLQ questionnaire in Romanian language involved adaptation, translation, and validation methodologies. The Romanian version was administered to 18 patients undergoing orthognathic surgery. **Results:** The adapted and validated version demonstrated satisfactory psychometric properties in term of reliability, sensitivity, and validity. The average Cronbach's alpha coefficient was 0.92, with a slightly lower value (0.79, p=0.046) observed for the Oral function domain. The Social aspects domain exhibited the highest value, recording an average Cronbach's alpha coefficient of 0.96. **Conclusions:** Dentofacial anomalies detrimentally impact the quality of life of orthognathic patients. The Romanian version of the OQLQ has proven its validity in assessing the quality of life among Romanian orthognathic patients. **Keywords:** DENTO-FACIAL ANOMALIES, ORTHO-GNATHIC TREATMENT, OQLQ.

The lives of individuals dealing with dentofacial abnormalities are significantly affected, and orthognathic surgery boasts a high success rate as a viable treatment. However, this positive outcome relies on various subjective factors such as patient expectations, anxiety levels associated with the condition, and the secondary psychological stress it causes, in addition to the defined goals of the medical team (1, 2).

People with dentofacial anomalies may experience both physical and mental challenges based on their condition and how they perceive their appearance, as well as how others perceive them. The primary reasons cited for seeking treatment by these patients often revolve around aesthetic and social concerns, which can profoundly impact their mental well-being (3).

Individuals experiencing dentofacial disfigurements commonly express heightened levels of stress, reduced self-esteem,

and increased challenges in navigating social interactions. Some evidence indicates that the severity of skeletal misalignment correlates with the prevalence of mental health issues (4). Tangible concerns stand as the second most frequently cited reasons prompting this population to seek treatment. These concerns encompass reduced occlusal (bite) function, speech difficulties, airway obstruction problems, and temporo-mandibular joint-related pain (5).

The physical and mental challenges faced by individuals with dentofacial deformities can significantly impact their overall quality of life. "Quality of life" is a broad term that encompasses how individuals perceive their circumstances concerning health, finances, and other aspects deemed significant in their lifestyle (6). Within the healthcare sector, there has been a growing emphasis on Health-Related Quality of Life (HRQOL), which evaluates the influence of an illness or its treatment on a patient's ability to perform everyday tasks and lead a normal life (7).

The Orthognathic Quality of Life Questionnaire (OQLQ), devised by Cunningham et al., stands as a notable example of a tool designed to measure Oral Health-Related Quality of Life (OHRQoL) specifically for assessing the impact of dentofacial deformities on individuals' lives. This questionnaire serves as a "condition-specific" instrument tailored to evaluate the quality-of-life outcomes in patients with these specific deformations (8). The Orthognathic Quality of Life Questionnaire (OQLQ) has been employed to assess the quality of life of patients with dentofacial deformities and to measure the impact of surgical interventions. This instrument has demonstrated greater sensitivity compared to conventional surveys. Furthermore, it has been translated into and validated in various languages (9). The aim of this study was to translate and validate the Orthognathic Quality of Life Questionnaire (OQLQ) for the population in Romania requiring orthognathic treatment.

MATERIALS AND METHODS

The Orthognathic Quality of Life Questionnaire (OQLQ) comprises 22 items, graded on a scale from 0, representing "no bother at all," to 4, signifying "a lot of bother." The OQLQ evaluates how an individual's dentofacial anomaly influences their quality of life across four domains: facial aesthetics (items 1, 7, 10, 11, and 14; scoring range 0 to 20), oral function (items 2 to 6; scoring range 0 to 20), awareness of dentofacial aesthetics (items 8, 9, 12, and 13; scoring range 0 to 16), and the social impact of dentofacial deformity (items 15 to 22; scoring range 0 to 32). Higher scores on the OQLQ suggest a lower quality of life. This questionnaire has been employed to assess the quality of life in individuals with dentofacial anomalies and the effects of surgical interventions (8).

Questionnaire translation

The validation process followed specific methodological steps. We have obtained the author's consent for the use of the questionnaire and its validation. The English OQLQ was translated into Romanian by two independent bilingual translators, both being native Romanian speakers. This resulted in two separate Romanian translations. Any disparities or differences in word choices between the two translations were deliberated upon by a consensus committee. This committee consisted of the translators and the principal investigator. Through discussion, discrepancies were addressed, and a common synthesized Romanian translation was created. The synthesized Romanian translation was then back translated into English by a native English speaker who was unaware of the original version. This step aimed to ensure the accuracy and con-

sistency of the translated questionnaire. All versions - original, translated, and back-translated - were consolidated and scrutinized by an expert panel comprising two orthognathic specialists and a methodologist. This panel offered feedback and modifications were made to the translations based on their suggestions and insights. The feedback from the expert panel was incorporated to refine and establish the final Romanian version of the OQLQ.

Patients' selection

Approval was secured from the institutional review board of the University of Medicine and Pharmacy Grigore T. Popa Iasi (no. 202/12.06.2022) prior starting the study. The study participants were selected from the Department of Orthodontics, University of Medicine and Pharmacy Grigore T. Popa Iasi. Inclusion criteria of participants were as follows: voluntary participation, aged 18 years or above, individuals with dentofacial anomalies who need orthognathic treatment, absence of diagnosed cognitive impairment, native Romanian speakers. Exclusion criteria were as follows: individuals with diagnosed with micrognathia, hemifacial microsomia deformities due to trauma, tumor and cleft lip and / or palate.

Informed consent was acquired from all participating individuals before their involvement in the study.

The information was processed in a specially designed database. The statistical study, depuration and recoding of the database was all undertaken with IBM SPSS Statistics 24.0. The statistical process of validation was done by study of the viability, reliability, sensitivity, and validity. The reliability was evaluated by analysis of the internal consistency using Cronbach's alpha. The sensitivity to change was evaluated by use of the effect size index and bivariate tests of statistical significance (Wilcoxon). The construct validity was evaluated by doing a factorial analysis to measure the concordance of the dimensions with the original model.

Statistical analysis

To assess internal consistency, Cronbach's alpha coefficient was calculated for each direction of the questionnaire. A Cronbach's alpha value exceeding 0.7 is considered suitable for comparing different patient groups using the questionnaire (12,13). For construct validity, a principal components analysis was conducted, and its validity was confirmed through Bartlett's test of sphericity and the Kaiser-Meyer-Olkin (KMO) measure (considered acceptable with values above 0.5). Repeatability was measured using the intra-class correlation coefficient (ICC). A strong correlation was determined when the ICC value exceeded 0.71, while a moderate correlation fell between 0.51 and 0.70. Statistical significance was defined as p-values less than 0.05 (two-sided).

RESULTS

The sample consisted of 18 participants, 11 of them being female. 83.3% of the participants came from urban areas, and 60.1% of them had completed university or postgraduate studies (tab. I).

The results of the statistical analysis for internal consistency, intra-class correlation, and Cronbach's alpha coefficient for each item are depicted in Table 1. The findings reveal that, for the domain of *aesthetic facial aspects*, the average Cronbach's alpha coefficient was 0.92, with item values ranging between 0.89 and 0.95 (p=0.010). Conversely, a lower average value (0.79, p=0.046) was observed for the Oral function domain. The highest value was recorded in the *social aspects'* domain, with an average Cronbach's alpha coefficient of 0.96; likewise, the intra-class correlation coefficient displayed the same value (p=0.000) (tab. II).

TABLE I.

The demographic characteristics of the study sample

	No.	%
Age	28.33±7.74 years	
Gender		
Female	11	61.1
Male	7	38.9
Residence		
Urban	15	83.3
Rural	3	16.7
Level of studies		
Secondary schools (8 classes)	1	5.6
High schools (12 classes)	3	16.7
post-secondary	1	5.6
Postgraduate (PhD)	2	11.1
University (Bachelor)	6	33.3
University (Master's)	5	27.8

TABLE II.

General Description, Internal Consistency, intra-class correlation coefficient of the OQLO

Domain / item	Cronbach`s alpha / item	Mean value	SD	Cronbach`s alpha/ domain	Intra-class correlation coefficient	p
Aesthetic facial aspects						
1. I am self-conscious about the appearance of my teeth	.95	2.22	1.43	.92	.93	0.010
7. I don't like seeing a side view of my face	.89	1.83	1.61			
10. I dislike having my photo-graph taken	.90	2.17	1.65			
11. I dislike being seen on video	.89	1.94	1.62			
14. I am self-conscious about my facial appearance	.90	2.00	1.49			
Oral function						
2. I have problems biting	.70	2.17	1.38	.79	.79	0.046
3. I have problems chewing	.71	2.11	1.23			
4. There are some foods I avoid eating because the way my teeth meet makes it difficult	.80	1.78	1.30			
5. I don't like eating in public places	.78	1.83	1.42			
6. I get pains in my face or jaw	.76	1.44	1.14			

Domain / item	Cronbach`s alpha / item	Mean value	SD	Cronbach`s alpha/ domain	Intra-class correlation coefficient	p
Concern about deformity						
8. I spend a lot of time studying my face in the mirror	.88	1.89	1.60	.88	.88	0.027
9. I spend a lot of time studying my teeth in the mirror	.85	2.17	1.50			
12. I often stare at other people's teeth	.86	2.39	1.65			
13. I often stare at other people's faces	.81	2.44	1.65			
Social aspects						
15. I try to cover my mouth when I meet people for the first time	.96	1.22	.80	.96	.96	0.000
16. I worry about meeting people for the first time	.95	1.33	1.18			
17. I worry that people will make hurtful comments about my appearance	.95	1.33	1.28			
18. I lack confidence when I am out socially	.95	1.61	1.29			
19. I don't like smiling when I meet people	.96	1.78	1.26			
20. I sometimes get depressed about my appearance	.95	1.67	1.32			
21. I sometimes think that people are staring at me	.95	1.78	1.21			
22. Comments about my appearance really upset me, even when I know people are only joking	.95	1.56	1.42			

The intra-class correlation coefficients (ICCs) for all subcategories, with a 95% confidence interval (CI), were as follows: 0.93 for *Aesthetic facial aspects*, 0.79 for *Oral function*, 0.98 for *Concern about deformity*, and 0.96 for *Social aspects*. The lowest recorded value was observed in the Oral function category (tab. II).

The Bartlett's sphericity tests yielded significance ($p = 0.016$), and the Kaiser-Meyer-Olkin measure was calculated at 0.921. These outcomes facilitated the execution of a factor analysis based on the correlation matrix. Six factors were identified, collectively explaining 75% of the variance. Given the interrelation among these factors, an orthogonal rotation method was utilized. Concerning *Aesthetic facial aspects* (5 items), the recorded values ranged from 0.77 to 0.88. In the instance of *Oral function* (5 items), values were observed between 0.70 and 0.88. For *Concern about deformity* (4 items), values ranged from 0.75 to 0.84. Regarding *Social aspects* (8 items), values fell within the range of 0.79 to 0.88 (tab. III).

TABLE III.

Bartlett's sphericity test and Kaiser-Meyer-Olkin measure

Domain / item	Mean value
Aesthetic facial aspects	
1. I am self-conscious about the appearance of my teeth	.82
7. I don't like seeing a side view of my face	.79
10. I dislike having my photograph taken	.88
11. I dislike being seen on video	.77
14. I am self-conscious about my facial appearance	.80
Oral function	
2. I have problems biting	.70
3. I have problems chewing	.81
4. There are some foods I avoid eating because the way my teeth meet makes it difficult	.88
5. I don't like eating in public places	.81
6. I get pains in my face or jaw	.74
Concern about deformity	
8. I spend a lot of time studying my face in the mirror	.79
9. I spend a lot of time studying my teeth in the mirror	.81
12. I often stare at other people's teeth	.84
13. I often stare at other people's faces	.75
Social aspects	
15. I try to cover my mouth when I meet people for the first time	.79
16. I worry about meeting people for the first time	.85
17. I worry that people will make hurtful comments about my appearance	.82

21. I sometimes think that people are staring at me	.82
22. Comments about my appearance really upset me, even when I know people are only joking	.83

DISCUSSION

One of the medical concerns significantly impacting the quality of life in the dental field relates to dentofacial issues. The primary reasons individuals seek treatment for their dentofacial abnormalities stem from developmental and chronic conditions leading to social hindrances, such as unconventional facial appearances. Although functional issues also contribute to the necessity for treatment, they are often overshadowed by the social repercussions stemming from the patient's facial appearance. Consequently, this is closely intertwined with the issue of Quality of Life (QoL) (14-16).

To generalize the results to different populations and to ensure that a study be-

comes a valuable international tool, it is crucial to use validated and properly adjusted questionnaires. Prior to implement a survey in a different population and social context than the one in which it was originally developed, it needs to undergo a process of transcultural adaptation. Given that a simple direct translation might overlook certain cultural subtleties, the objective is to construct an instrument that closely reflects the original (9, 12, 13).

The most widely used method for semantic and cultural adaptation involves a process known as back-translation, carried out by bilingual experts. This is followed by a thorough analysis of the resulting version, which is then refined to assess its psychometric properties such as reliability, internal consistency, and sensitivity. Reliability refers to an instrument's capability to generate consistent results each time it is used. Internal consistency, which assesses the similarity of responses related to the same concept, is used to assess this reliability. In our study, using Cronbach's alpha, we obtained values exceeding 0.7 for all domains, indicating that the new version demonstrates adequate internal consistency. Sensitivity depends on the nature of an instrument to recognize genuine cases.

The OQLQ has been demonstrated as a straightforward and user-friendly language questionnaire that can be easily understood by individuals. This validation further confirms the reproducibility, reliability, validity, and comparability of the OQLQ when compared to its original form (17-20).

The reliability of the OQLQ was excellent, with a high Cronbach's alpha value ranging between 0.89 and 0.95. Specifically, the Cronbach's alpha value for the overall score exceeded 0.9, while the intraclass correlation coefficient was higher than 0.8 for three out of four domains, with Oral function being slightly lower than 0.8. Most validated versions of the OQLQ, including the original scale (20), show Cronbach's alpha values similar to the results observed in the Romanian adaptation of the OQLQ. This outcome suggests that the study demonstrated reliability for repeated assessments and maintained high consistency over time.

CONCLUSIONS

Romanian version of OQLQ demonstrated validity, reliability and sensitivity in evaluating the quality of life of patients who require orthognathic treatment, the results being consistent and comparable with those of the original version.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest and they received no funding.

PREDICTORS OF ADMISSION/NON-ADMISSION INTO THE HOSPITAL, HEALTH EFFECTS, AND METEOROLOGICAL FACTORS RELATED TO A VIOLENT STORM IN TIMISOARA, ROMANIA (Abstract): The aim of the performed study is to investigate predictors of admission/non-admission into the hospital, health effects and meteorological factors related to a violent storm that happened on the 17th of September 2017, in Timisoara, Romania. **Materials and methods:** Case-study with a 6-day retrospective investigation (15th-20th September) of admissions/non-admissions, all health effects and storm-trauma health effects, and meteorological factors on a sample of 1,156 patients (54.93% males, 45.07% females) who came to the ERU, sample that included a "storm-trauma" sample of 71 patients (60.60% males, 39.40% females). **Results:** Three subgroups of the entire sample were considered: before storm-no effects (15th-16th), during and after the storm-immediate effects (17th-18th and after the storm-delayed effects (19th-20th of September). Traumatic health effects (16.7% of trauma, 13.3%-due to the storm) and meteorological factors values (air temperature-31.6^{0}C, air pressure-732 mmHg, gust wind speed-106.92 Km/h-violent storm) were recorded on the 17th of September. **Discussion:** Main predictors for admission into the hospital were covariate: mean air temperature (OR=1.924, P<0.001), relative humidity and age increase, and categorical: cardiac diseases (OR=0.436, P<0.001), fractures (OR=0.375, P<0.001), and urban/rural environment. A primary categorical predictor for non-admission into the hospital was contusions. A subgroup of population exposed to the storm (17th-18th of September) recorded significant differences in term of being admitted into the hospital in comparison with the other two subgroups. **Conclusions:** there is a relation between admissions/non-admissions into the hospital and personal characteristics (age, rural/urban), health effects (cardiac diseases, fractures, contusions), and meteorological factors (air temperature, humidity, pressure) in the context of the violent-storm. **Keywords:** ADMISSION, HOSPITAL, HEALTH EFFECTS, METEOROLOGICAL FACTORS, STORM.

INTRODUCTION

On the 17th of September 2017 at 3.40 p.m. a violent storm happened in the Western region of Romania. Under the conditions of a particularly strong thermal contrast (the quick decrease of the air temperature from 31-32°C to 16°C) the base of the formed clouds was very close to the ground (500-600 meters), while their peak reached 10,000-13,000 meters and caused the pro-

duction of these particularly violent phenomena. An orange code was issued at 3.38 p.m. (1), but since it was a Sunday, people were outdoors and relaxing. Severe health effects and environmental damages followed the storm: 8 people died and 67 were wounded (2). It was a mid-latitude storm, with around 100 Km^2 surface area (Western region of the country- large disaster) and small number of deaths (8- small disaster) (3, 4). Several trees and several buildings were damaged. People were also injured as a result of trying to repair the damage done to buildings and trees. The Emergency Receiving Unit (ERU) of the County Emergency Clinical Hospital performed the reception, consultation and referral of patients to hospitals' departments. Current research that has been carried out on the impact of climate change at global and regional level reviewed vulnerabilities of the natural world and human societies to adapt to climate change and extreme weather events (5). Older persons and their families employed predictive and adaptive strategies to avoid and minimize extreme weather impacts (6). Vital lessons could be learned from extreme weather events and a management strategy for wind disasters is important for planning in advance a well prepared and prompt response to potential damages involving health (7). Certain studies on extreme weather events in the area have described a historic afternoon pattern of tornadoes in the Eastern region of the country (8) and an inappropriate behavior of the population during and immediately following a disaster (9). A lack of knowledge is observed regarding health effects of extreme weather events in the Western region of the country. A framework consisting of rapid needs assessments, health surveillance, tracking, registries and epidemiological investigations, including risk factors and health outcome studies and evaluation of interventions need to be applied throughout a disaster management cycle. Epidemiological methods (case-studies) have to be routinely integrated into disaster response and fully communicated to response leaders (10). The aim of this study is to investigate predictors of admission/non-admission into the hospital, the health effects, and the meteorological factors that are related to a violent storm.

MATERIALS AND METHODS

The study was performed on a "retrospective 6-day investigation" sample of 1,156 patients (54.93% males and 45.07% females, aged 8-93 years) with an included "storm-trauma" sample of 71 patients (60.6% males and 39.4% females, aged 9-91 years), patients who were received at the Emergency Receiving Unit (ERU) of the County Emergency Clinical Hospital, in the context of a violent storm that happened on the 17th of September 2017. The "retrospective 6-day investigation" sample consisted of patients who were received at the ERU over the course of 6 days (15th-20th September, 2017) considering all health effects. The "storm-trauma" sample consisted of patients received at the ERU from the 17th of September at 4 p.m. to the 18th of September at 8 p.m., considering traumatic health effects due to the storm. The daily distribution of patients received at the ERU can be seen in tables I and II.

The method consisted of a case-study with a retrospective 6-day investigation (15th -20th of September) using:

Primary medical evidence: patients who went or were taken to the ERU; patients who were/not were admitted into the hospital; all health effects and storm related

trauma health effects;

The meteorological factors: temperature-^{o}C, relative humidity-%, precipitations-liters/m^2, pressure-mmHg, wind speed-Km/h, sunshine-hours) established at the Regional Meteorological Center.

The storm happened on the 17th of September and lasted 20 minutes (from 3:40 to 4:00 p.m.), all the population in the area were exposed to the specific meteorological factors. In order to separate the population exposed to the storm from the population not exposed the author considered: 15th-16th of September corresponding to before storm- no effects; 17th-18th of September - during and immediate effects of the storm; 19th -20th of September - after the storm- delayed effects.

Statistical analysis (frequency, Kruskal Wallis, Mann-Whitney with Bonferroni correction, Chi square, ANOVA one way and binary logistic regression) was performed with the aid of *SPSS 20* software (11). Storm trauma effects were analyzed considering the frequency due to the small size of the sample. Statistical comparison between 2-day distribution series of patients was performed by the aid of Kruskal Wallis, Mann-Whitney with Bonferroni correction and *Chi square* analysis for categorical variables (gender, rural/urban, diagnostics, admission/non-admission into the hospital) and ANOVA one way for covariate variables (age, meteorological factors).

Personal predictors (gender, age and urban/rural environment), time predictors (date and hour of patients' reception at the ERU), established diagnostics and meteorological factors (temperature, humidity, precipitations, wind speed, pressure and sunshine) as possible predictors were analyzed for the entire sample relative to admission/non-admission of patients into the hospital sections or the other medical units from the ERU, using binary logistic regression. This type of regression uses the dependent variable consisting of only two nominal categories (admission/non-admission into the hospital), and any score (covariate: age, temperature, humidity, wind velocity and pressure values) or nominal (categorical: gender, rural/urban environment, daily and hourly presentation to the ERU, diagnostics) variables can be used as the predictors. The reference category is the non-admissions into the hospital for categorical variables. A similar analysis was performed for admitted patients with the main associated diagnostics (presence/absence of diagnostic) as dependent variable related to personal characteristics, time, and meteorological possible predictors.

The author asked for and received from the County Hospital Leadership the agreement to access primary evidence while keeping this evidence confidential and respecting the personal data protection law. The medical data were already collected for medical and statistical purpose, with the requested and received individual consent of the patients. The initial outcome of all health effects data registration was for medical and statistical purpose, and the initial outcome of the traumatic health effects due to the storm data collection was to report to local and national authorities. The agreement (no. 8/22.03.2019) of the University of Medicine and Pharmacy's Ethical Commission was requested and obtained (for this statistical clinical study).

RESULTS

Daily and hourly presentation of patients to the ERU

Daily presentations of patients to the ERU recorded the highest frequencies on

the 17th (17.39%), 18th (18.94%) and 19th (17.48% of patients) of September, 2017 (tab. I). The highest frequency of patients received at the ERU due to storm related trauma was recorded on the 17th of September, 2017 (76.06% of patients) (tab. II).

Hourly evolution of the all causes related trauma and of the storm related trauma emergencies observed during the 17th and 18th of September, 2017 reveals the greatest numbers of patients with traumatic health effects due to the storm on the 17th of September between 4 p.m. and 9 p.m. (48 patients) and on the 18th of September between 12 a.m. and 8 p.m. (17 patients) in the context of all trauma health effects (fig. 1).

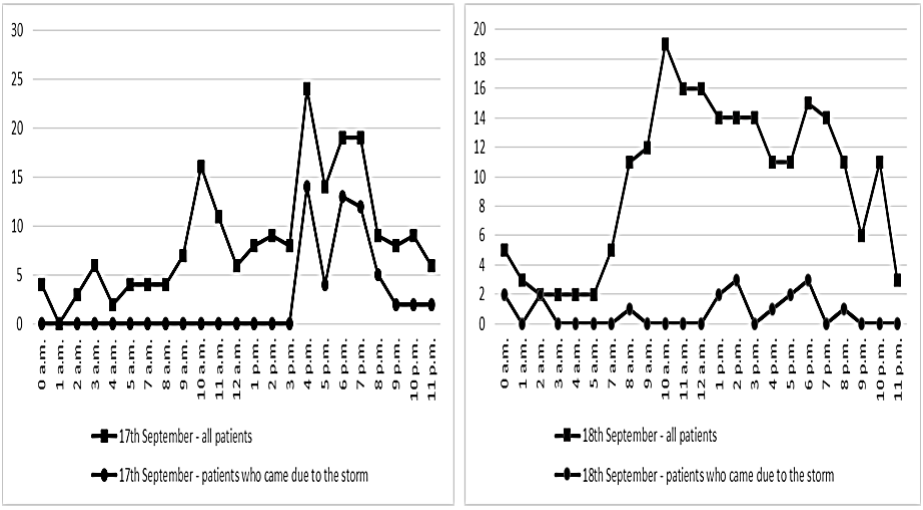

Fig.1. Hourly-evolution of all patients and patients who came at the ERU due to the storm (17th-18th September)

Personal features (gender, age, and rural/urban environment)

Patients who went or were taken to the ERU during the retrospective 6-day investigation for all health effects were more frequently males (54.9%) than females (45.1%) with a peak on the 18th of September for males (57.5%) (tab. I). Patients who went or were taken to the ERU due to the storm related trauma were more frequently males (60.6%) than females (30.4%) with peaks on the 17th of September for both genders: males-32 patients and females-22 patients (tab. II).

Age groups distribution of patients who went or were taken to the ERU with all health effects from the 15th to 20th of September 2017 recorded the greatest frequencies at ages 60-70 (16.9%), 20-30 (15.2%) years (tab. I). For patients who arrived at the ERU with storm related trauma on the 17th and 18th of September the highest frequencies were recorded for ages 50-60 (26.8%) and 20-40 (38%) years (tab. II).

Between the 15th and 20th of September, the patients from urban area came or were taken to the ERU more frequently than patients from rural area (tab. I). During the 17th-18th of September period, the frequency of patients who came from rural area increased (from 43.8% to 52.1%, respectively) and the frequency of patients who came from urban area decreased (from 56.2% to 47.9%, respectively). On the 18th

of September the frequency of patients from rural areas (52.1%) was higher than patients from urban areas (47.9%) (tab. II). Patients who were directly affected (with trauma) by the storm came to the ERU more frequently from rural (38, 53.5%) than from urban (33, 46.5%) areas (tab. II).

There was no statistically significant difference (Kruskal-Wallis, Mann-Whitney with Bonferroni correction) in the personal characteristics of patients who came or were taken to the ERU before, during and after the storm 2-day samples.

Health effects

All diagnostics distribution in the patient population received at the ERU during the retrospective 6-day investigation (15th-20th September) can be seen in first table. An increase of frequencies was recorded for neurologic (199; 13.7%), digestive (162; 11.2%) diseases, contusions (159; 11%), urinary diseases (112; 7.7%), fractures (100; 6.9%) and cardiac diseases (94; 6.5%). There was no statistically significant difference (Kruskal-Wallis, Mann-Whitney with Bonferroni correction) in the diagnostics of patients who came or were taken to the ERU before, during and after storm.

Traumatic health effects

The greatest numbers of trauma diagnostics were recorded on the 18th (166 diagnostics, 28.7%) and 17th (97 diagnostics, 16.7%) of September 2017 (tab. I). During these 2 days 45.8% of all trauma were observed, 19.3% (112 diagnostics) of them due to the storm, according to the patients' statements (tab. II).

Traumatic health effects due to the storm

Traumatic health effects due to the storm could be seen in comparison with all trauma diagnostics on the 17th (amputations-1/1, contusive wounds-21/21, cut wounds-5/5, CCT-cranial-cerebral trauma-17/17 and fractures-15/15) and 18th of September (contusions-7/47, CCT-4/13, fractures-9/26, and sprains-5/13) (fig. 2).

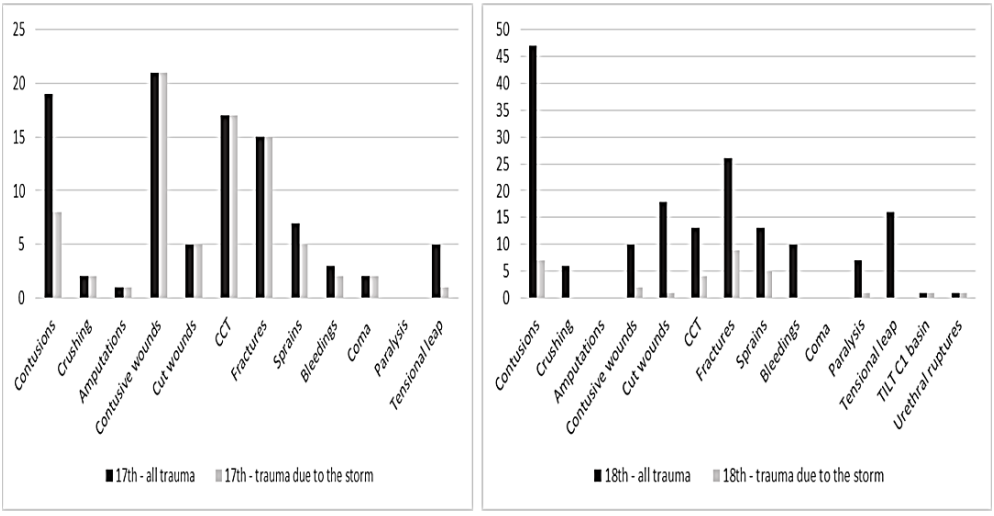

Fig. 2. All traumatic health effects and traumatic health effects due to the storm, seen comparatively (17th-18th September)

Admissions/non-admissions into the hospital

Over the period from the 15th to the 20th of September, the patients who were received, consulted and treated at the ERU were sent home (829; 71.7%), or they were admitted to the hospital sections (327; 28.2%) as follows: surgery (71; 6.1%), neurosurgery (36; 3.1%), neurology (43; 3.7%), orthopedics, traumatology and politraumatology (32; 2.8%), gastroenterology (20; 1.7%), cardiology (17; 1.5%), infectious diseases (15; 1.3%) (fig. 3).

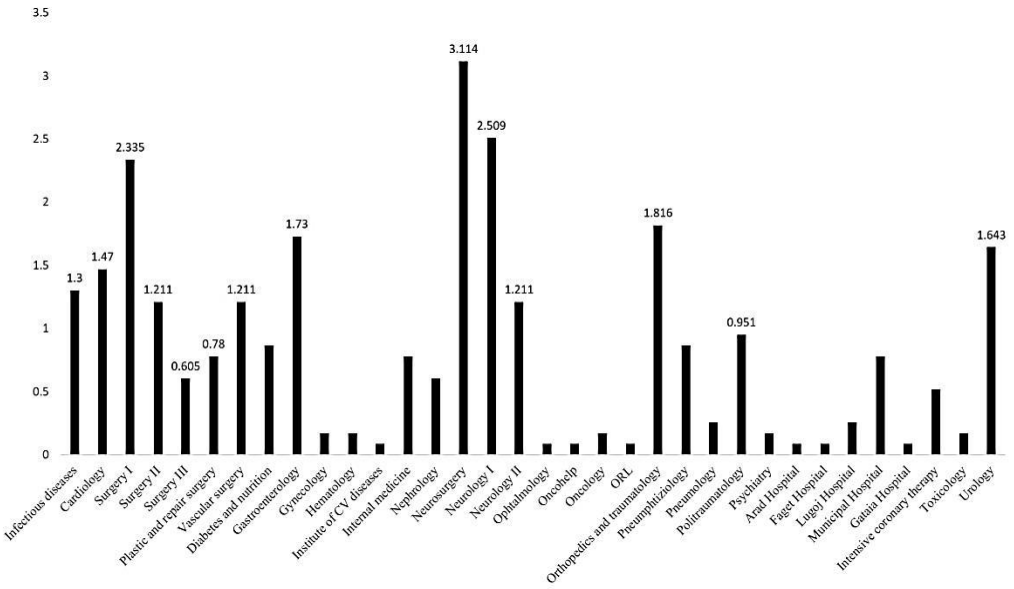

Fig. 3. Patients' distribution (%) according to hospital sections to which they were sent from the ERU

Daily admission/non-admission into the hospital can be seen in tables I and II. Admission of patients into the hospital was the highest in term of frequency in the 17th and 18th of September for all diagnostics (22.3% and 24.8%, respectively) and for trauma due to the storm diagnostics (23.9% and 15.5%, respectively).

A statistically significant difference (Chi Square=25.97, P<0.001) of admitted patients between time series (15th-16th, 17th-18th and 19th-20th of September) was found as follows: between 15th-16th and 17th-18th (Mann-Whitney: z=-4.87, P<0.001) and between 17th-18th and 19th-20th (Mann-Whitney: z=-3.306, P=0.001). No difference (Mann-Whitney: z=-1.674, P=0.094) of admitted patients was recorded between 15th-16th and 19th-20th of September.

Patients affected directly by the storm were more frequently admitted (28 patients, 39.4%) into the hospital than patients from the 6-day investigation sample (327; 28.2%). Most frequently admitted into the hospital due to the storm were male patients (26.7%), age group 50-60 years (11.2%), from the rural environment (25.4%), with fractures (12.7%), on the 17th of September (23.9%), when the violent storm happened.

Meteorological factors

The highest values of the air temperature (mean-21.2ºC, maximum-31.6ºC and minimum-16.1°C) and of the wind speed (mean-7.2 Km/h, maximum-19.08 Km/h, and at gust-106.92 Km/h) were recorded on the 17th of September. Large variation of air temperature (difference between maximum-31.6°C and minimum-16.1°C) during the same day could be noticed. Low values of air pressure (mean-735.5 mmHg, maximum-737 mmHg and minimum-732.1 mmHg) were recorded on the 17th of September (tab. III) in association with precipitations (6 liters/m^2) and only 3.4 hours of sunshine. Gust wind speed indicated a violent storm on the Beaufort scale (level 11) on the 17th of September (fig. 4).

Table III.

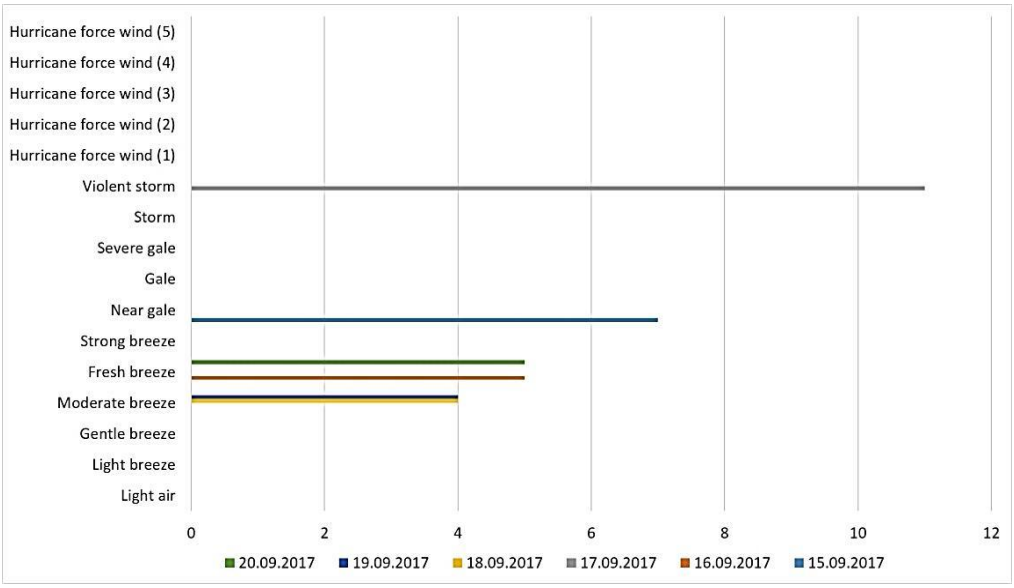

Fig. 4. Wind speed at gust over the investigated 6-day period on the Beaufort scale

There was a statistically significant difference (ANOVA) between air temperature recorded on 19th-20th of September and the other 2 time series 15th-16th (P<0.001) and 17th-18th September (P<0.001) as follows: mean air temperature (F=317.402, P<0.000), maximum air temperature (F=201.204, P<0.000) and minimum air temperature (F=240.641, P<0.001).

Mean air pressure recorded a statistically significant difference between the three time-series (ANOVA: F=467.596, P<0.001) with post hoc: 19th-20th and 15th-16th of September (P<0.001); and 19th-20th and 17th-18th of September (P<0.001). Air pressure maximum presented a statistically significant difference (ANOVA: F=203.901, P<0.001) between each of the three time-series.

Wind speed mean (F=79.355, P<0.001) and wind speed maximum (F=277.885, P<0.001) presented significant statistical differences between 15th-16th of September, and 17th-18th and 19th-20th series (*post hoc*, P<0.001).

Predictors of admission/non-admission into the hospital

Most relevant predictors of admission/non-admission into the hospital were established for the entire 6-day investigation sample of patients who came to the ERU.

Personal predictors (urban/rural environment, age)

An interesting result was obtained for the urban/rural environment categorical predictor related to admission/non-admission into the hospital. Reference for admission/non-admission was the last category (non-admission) for categorical variables. Patients who came from urban areas were more frequently non-admitted (B=0.563-good influence of predictor, P=0.001, Exp(B)= 1.755=Odd Ratio (OR) - an increase of non-admission of patients from urban area). The change in-2 Log Likelihood= 16.778= Chi square (χ^2) was significant (P=0.001) and supported the prediction (tab. IV). As a complementary result, patients who came to the ERU from the rural areas were more frequently admitted to the hospital than the patients who came from urban areas.

Age resulted as a covariate predictor significant for admission/non-admission into the hospital (B=0.033, OR=1.033 (95% CI: 1.026-1.041), χ^2=85.677, P<0.001) (tab. IV). An increase of admission into the hospital is predicted by an increase of patients' age. The model is 70.7% accurate.

Time predictors (date, hour)

Date and hour at which the patients were at the ERU were not found as predictors or influencing factors on admission/non-admission into the hospital.

Established diagnostics as predictors

Main diagnostics that resulted as categorical predictors for admission/non-admission of patients into the hospital were: cardiac diseases (B=-0.831, OR=0.436, 95% CI: 0.279-0.681, χ^2=12.997, P <0.001), fractures (B=-0.982, OR=0.375, 95% CI: 0.239-0.589, χ^2=17.612, P <0.001), and digestive diseases (B=-0.589, OR=0.555, 95% CI: 0.387-0.794, χ^2=10.171, P=0.001) (tab. IV). Negative values for B and Exp(B)=OR<1 indicate a decrease of non-admission (reference-last category=non-admission) into the hospital and a complementary increase of admission of patients into the hospital.

Other diagnostics that resulted as categorical predictors for admission/non-admission of patients into the hospital were: contusions (B=0.740, OR=2.096, 95% CI: 1.333-3.298, χ^2=11.419, P=0.001),

sprains (B=1.337, OR= 3.807, 95% CI: 1.337-10.838, P=0.012, χ^2=8.773), cut wounds (B=1.211, OR= 3.357, 95% CI: 1.306-8.625, P=0.012, χ^2=8.449) and psychiatric diseases-panic attacks (B=1.518, OR=4.564, 95% CI: 1.376-15.137, P=0.013, χ^2=9.101). Positive values for B and OR>1 indicate an increase of non-admission (reference-last category-non-admission) into the hospital (tab. IV). The model was 70.3% accurate.

Meteorological factors as predictors

Meteorological factors found as covariate predictors for admitted/not admitted patients who went or were taken to the ERU were: average air temperature (B=0.654, OR=1.924, 95% CI: 1.403-2.638, χ^2=17.408, P<0.001), maximum air temperature (B=-0.228, OR=0.796, 95% CI: 0.698-0.909, χ^2= 12.217, P<0.001) and relative humidity (B=0.065, OR=1.067, 95% CI: 1.035-1.101, χ^2=17.165, P<0.001) (tab. IV). Positive values of B and Exp(B)>1, 95% CI values>1 indicate an increase of hospital admission when the covariate predictors (mean air temperature between 16^0C-20^0C and relative humidity between 50%-80%) increase. Negative values of B and Exp(B)<1 indicate an increase of admissions into the hospital when the covariate predictor (maximum air temperature between 26°C-20°C) decreases. The model was 71% accurate (tab. IV).

TABLE IV.

Predictors of admission/non-admission into the hospital (n=327/n=829)

Personal predictors		B	Adjusted OR (95% CI)	*P*-value	Chi square	*P*-value
Step 1[a]	Age	0.033	1.033 (1.026-1.041)	0.000	85.677	0.000

a. Variable(s) entered on step 1: age, gender, and urban/rural environment. b. Variable(s) entered on step 1: cardiac, digestive diseases, contusions, and contusive wounds, cut wounds, fractures, sprains, psychiatric.

Predictors for main diseases of the patients admitted into the hospital

An interesting result was obtained for predictors of cardiac diseases and fractures.

Predictors of cardiac diseases

For cardiac diseases the main predictors were the age (B=0.038, OR=1.038, P<0.001, χ^2=42.516), and air pressure maximum (B=0.195, OR=1.215, P=0.002, χ^2=10.326, P=0.001). An increase of age and air pressure maximum (between 739 mmHg-741 mmHg) determines an increase in the number of patients with cardiac diseases. The model was 91.8% accurate. Both limits of air pressure maximum are situated under 760 mmHg (normal value at the sea level).

Predictors of fractures

For fractures the main predictors was the air pressure maximum (B=0.160, OR=1.173, and P=0.01, χ^2=7.213, P=0.007). An increase of air pressure maximum (between 739 mmHg-741 mmHg) relates to an increase of the frequency in which fractures occurred.

It is interesting that maximum pressure values between 739 and 741mmHg were recorded on the 18th of September. This means one day after the storm happened, when resulted an increase in the rate of these 2 diseases. The models were 74% accurate.

DISCUSSION

In the study performed the health effects in patients who went or were taken to the ERU due to common causes and due to a violent storm were retrospectively investigated. Use of the emergency health information offered to the author the possibility to analyze all health effects and health effects due to the violent storm, time evolution of patients received at the ERU, personal characteristics and admissions/non-admissions into hospital. The entire process that was analyzed happened in the context of population exposure to specific meteorological factors before, during and after the storm. The retrospective approach of extreme weather phenomena related to health effects recorded at emergency department is frequently mentioned in research literature in order to investigate the impact on population in real situations (12) and to assess the risk as an implementation strategy to reduce the negative impact on the population exposed (13).

Age distribution of the patients who were received most frequently at the ERU during the performed case-study indicates two age groups: old people (60-70 years) and young adults (20-30 years). Research in the field describes length of time spent in the emergency department for patients over 70 years (14) and an association between wind disasters and emergency department visits by age and causes (injuries, cardiac diseases for people over 65 years and renal diseases for people between 18-64 years) (15).

During the retrospective 6-day investigation the gender distribution of patients who were taken to the ERU was higher for males than for females, and the difference between the two genders distribution increased when the main reason for their needing medical attention at the ERU was injury due to the storm. The role of gender in emergency research and practice was mentioned in certain studies that consider trauma diseases (16) or cardiovascular diseases (17).

Patients who arrived at the ERU during

the retrospective 6-day investigation came more frequently from urban than rural areas. During the 17th and 18th of September, the days when the patients affected directly by the storm came to the ERU along with the other patients, those affected by the storm came more frequently from rural than from urban areas. The primary care system capacity in rural areas could be inadequate for responding to storm (18). Research literature regarding rural emergency management of public health crisis identifies as solutions: permanent institutions; improving interventions at the pre-disaster, disaster and post-disaster stages; investments and a reserve system of resources (19). On the other hand, the attitude and the response capacity of primary care medical staff in a rural area proved to be poor in another study (20).

Many patients who were affected by the storm went or were taken to the ERU between 4 p.m. and 9 p.m. on the 17th of September and between 12 a.m. and 8 p.m. on the 18th of September. The greatest percentage in terms of frequency of patients who arrived at the ERU was recorded there from the 17th to the 19th of September. An important aspect is that this violent storm happened on Sunday, during the weekend. In the performed study, the days of the week and the hours did not impact significantly the activity of ERU. In other research studies, on the other hand, the day of the week was shown to be an important factor (especially during the weekend) that could impact the Emergency Department efficiency: more time caring for emergency patients, less median specialist intensity or higher mortality at admission (21).

Health effects diagnosed in patients who came to the ERU were most frequently neurologic diseases, digestive diseases, contusions, urinary diseases, fractures and cardiac diseases. The number of admitted conditions (15) resulted in another research was similar to the study performed (17, if all trauma conditions are considered trauma), although they seem to be of a different order in terms of magnitude (22). Fractures and cardiac diseases most frequently resulted in hospital admissions. The research literature mentions acute myocardial infarction as one of the main causes of mortality in emergency department for non-traumatic diseases (23).

When traumatic health effects were analyzed over the entire 6-day period, resulted that the greatest frequency of trauma happened during the two day-period of the 17th to the 18th of September. Moreover, certain traumatic diseases were frequent and directly connected with the storm during these 2 days, such as: contusive wounds, CCT, fractures, sprains, contusions and cut wounds. Another study of trauma showed that women mainly experienced fractures and contusions/abrasions, whereas men experienced open wounds (24). Traumatic brain injuries found in the performed study were also investigated in research literature with the purpose of improving the efficiency of the emergency departments' management of patients with mild traumatic brain injuries (25).

An important aspect pursued in this case-study with the retrospective 6-day investigation was the admission and non-admission to the hospital (sending the patients home). A great proportion of patients (2/3 - 3/4) of the total number were received, consulted, treated at the ERU and sent home (26). The hospital sections that most frequently received patients who were admitted to the ERU were: surgery, neurosurgery, neurology, orthopedics and trau-

matology and politraumatology, cardiology and infectious diseases. Current research demonstrated that a proposed mobile emergency medical center (MEMC) facilitated transportation of patients with 2 lines ambulances which transported patients in critical condition: between MEMC and disaster, and from the MEMC to the requested hospitals for further treatment (27). In another study polytrauma was seen in the majority of patients and the affected hospital had the uphill task of treating hospitalized patients as well as disaster victims (28). A significant difference was found in the performed study when admissions into the hospital during and immediately after the storm (17th-18th of September) were compared to admissions before the storm (15th-16th), and to admissions after the storm (19th-20th of September). Concerns about weather-related injury were noticed in another study (29).

Meteorological factors investigated during the retrospective 6-day investigation (15th-20th September) indicated the maximum, minimum and the greatest difference between maximum and minimum temperature in the same day, 17th September 2017. Low pressure values were associated with precipitation on the 17th and 20th of September. Gust wind speed surpassed 100 Km/h and indicated a violent storm on the 17th of September. Wind disaster, one of the hazards included in classification of meteorological disasters, was investigated in China (30).

When time series (15th-16th, 17th-18th and 19th-20th of September) of meteorological factors were considered, there was a significant difference between 19th-20th of September and the other 2 series for air temperature and air pressure and a significant difference between the 15th-16th of September and the other 2 series for wind speed. In other research studies outdoor air temperature and related meteorological parameters were associated with stroke attack (30) or with behavioral change with temperature increase (32). Different kinds of incidents in Europe with extreme weather events demonstrated effects of meteorological factors and climate change on public health (33).

Although, no statistically significant differences were found between time series of patients (15th-16th - not exposed, 17th-18th - exposed with immediate effects; and 19th -20th of September - exposed with delayed effects) regarding personal characteristics (gender, age, rural/urban) and pathology, there were significant differences in term of being admitted into the hospital.

Main predictors of admission/non-admission into the hospital of patients from the ERU were:

•Age increase, cardiac diseases, digestive diseases, fractures, mean air temperature and relative humidity increase, which predict admission in hospital.

•Urban environment, contusions, contusive wounds, cut wounds, and maximum air temperature increase, which predict non-admission into the hospital.

Another study (28) demonstrated that there was an interrelation of risk factors or a risk factors cascade triggered by individual or a cluster of risk factors. Therefore, extraordinary events (such as violent storms) or a crisis ordinarily have the so-called cascade effect. An example of this may be windstorm, resulting in a power outage and affecting hospitals, where it is essential for acute care clients to have a regular intake of electrical energy to ensure their life functions (33). By reducing hu-

man vulnerability to disasters, we can lessen--and at times even prevent their impact (34). Communities resilient to the health risks of climate change anticipate risks; reduce vulnerability to those risks; prepare for and respond quickly and effectively to threats; and recover faster, with increased capacity to prepare for and respond to the next threat (35). Preparing for anticipated effects of disasters can help reduce the public health and economic burden (36). Technical and operational synergies are identified to link disaster risk research and communities' adaptation in health (37).

In the performed study main predictors of the main diseases (cardiac and fractures) which led to admissions into the hospital were: age increase for cardiac diseases and air pressure maximum increase for cardiac diseases and for fractures. In research literature the increased incidence rate of ischemic stroke was consistent with the daily lowest and highest air pressure, highest air temperature and presence of hurricanes or storm (38). When confronting changing weather conditions, thinking in ecological terms about the determinants of health, disease and death in human population was considered critically important in another study (39).

The retrospective 6-day investigation offered us valuable information on the efficiency of the ERU, the pathology they usually encounter and the pathology they face in an extreme weather event. A limit of this study is that it is an observational one.

CONCLUSIONS

A relevant prediction of admission/non-admission into the hospital was found for the entire investigation sample. Main predictors of admissions into the hospital related to the storm are: rural environment, increase in age, cardiac diseases, digestive diseases, fractures, average air temperature and relative humidity increase. Main predictors of sending patients home are: urban environment, decrease in age, contusions, cut wounds, sprains, psychiatric diseases (panic attacks) and maximum air temperature increase. Main predictors for diseases with which patients were admitted to the hospital are age increase (cardiac diseases) and air pressure maximum increase 739-741 mmHg (cardiac diseases and fractures). There is a significant difference between admissions into the hospital during 17th-18th of September and the other two time series. Traumatic health effects were the most frequently recorded at the ERU during the 18th and 17th of September (mainly due to the storm). The greatest variation of air temperature, the gust wind (violent storm on the Beaufort scale) and the lowest values of air pressure were recorded during the storm, on the 17th of September. There is a relation between admission or non-admissions of people into the hospital and personal predictors, health effects, and meteorological factors in the context of the violent storm.

ACKNOWLEDGMENTS

The author wishes to offer her recognition for the great support offered in medical data base building by Prof. Dr. Marius Craina, manager of the County Emergency Clinical Hospital "Pius Brinzeu" Timisoara, Dr. Mihai Grecu, Chief Medical Officer UPU SMURD (ERU), Prof. Dr. Horia Cristian, Coordinator of the Center of Traumatology "Austria House" Timisoara, Prof. Dr. Jenel M. Patrascu, Chief of the Clinical Orthopedic and Traumatology Section II and Prof. Dr. Radu Prejbeanu, Chief of the Clinical Orthopedic

and Traumatology Section I, Timisoara, Assist. Univ. Dr. Ivan Mihaela-Viviana - Head of the Department of Cardiology, Prof. univ. Dr. Rodica Avram, Department of Cardiology, Prof. Dr. Jianu Dragos Catalin - Chief of the Department of Neurology I and Prof. Dr. Adriana Mihaela Simu, Chief of the Department of Neurology II, and Associate Professor Dr. Dehelean Liana, Chief of the Department of Psychiatry II, Timisoara. Great recognition I wish to offer to Mrs. Silvia Barbu, Meteorologist and Director of the Regional Meteorological Center Banat-Crisana, Romania who offered me constant support with knowledge and data base for meteorological data base building. Many thanks to Claudia Mirela Dinca, and to all the medical recorders who have supported the needed completion of the medical data base.

STATEMENT OF ETHICS

All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and/or national research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards. The Ethical Agreement No. 8/22.03.2019 was requested and obtained from the "Victor Babes" University of Medicine and Pharmacy Timisoara's Ethical Commission, for this statistical clinical study.

CONFLICTS OF INTEREST AND FUNDING

The author declares that the research was conducted in the absence of any commercial or financial relationships that could be considered as a potential conflict of interest.

The author declares that there is no conflict of interest regarding the publication of this paper. There was no institutional funding for this study.

CONSIDERATIONS REGARDING THE QUALITY OF LIFE IN PATIENTS WITH TRAUMA ADMITTED TO AN EMERGENCY DEPARTMENT (Abstract): Quality of life (QoL) is an important outcome indicator in assessing interventions and medical treatments, in order to understand the burden of disease and identify health issues. **The study aim** was to assess the QoL of patients admitted in an Emergency Department, with polytrauma, by applying the SF-12 validated questionnaire. **Materials and methods:** The study group consisted of 101 subjects, aged 15-17, admitted in the "Sf. Ioan" Children's Emergency Hospital, Galati. **Results:** The Cronbach alpha coefficient was 0.707; mean age 16.43 ±0.88; 69.3% males; 56.4% from urban areas; traumas diagnosed in 19.8% of patients. The mean SF-12 score was significantly lower in patients with sprain (score=89.20) or polytrauma (score=89.90) (p=0.018); slightly lower in patients whose physical and emotional health greatly affected social activities. The degree of impairment in the patient who felt a lot of change in physical and/or emotional health reduced the SF-12 score by 20% (p=0.829). Very intense body pain was associated with a 24% lower SF-12 global score (p=0.308). The mean level of SF-12 scores differed significantly depending on the general health status (p=0.001): on the total study group, a reduced impairment of the QoL was revealed, the mean score was 91.95±7.67, representing 85.9% of the maximum value recorded; the lowest mean value was recorded in patients with a poor general condition (86.67±11.93). **Conclusions**: The QoL in pediatric patients admitted with various types of trauma did not differ significantly between age groups, sexes or residential environments. The global SF-12 score revealed a decrease in the QoL, due to by the very intense bodily pains that significantly affected the patients' physical and emotional health. **Keywords**: CHILD, EMERGENCY, QUALITY OF LIFE, QUESTIONNAIRE.

The concept of quality of life (QoL) was included as one of the basic principles in the Constitution of the World Health Organization (WHO) through the very definition of the notion of health as "a state of physical, mental and social well-being and not merely the absence of disease or infirmity". Currently, there is an increasing interest in the field of QL and specific attention is paid to traumatic brain injury, orthopedic injuries, family stress and post-traumatic stress disorder (1). Studies have noted difficulties with variability in participant characteristics, health-related quality of life measures, and duration of patient follow-up across cohort studies over longer

periods of time (2).

The QoL in children significantly affects that of the parents and the family. Vast pediatric conditions, from common viral and bacterial infections (3), tuberculosis (4) from minor trauma to polytrauma, have an important impact on the QoL in pediatric patient and their families. There are a number of questionnaires available to assess the quality of pediatrics, which are versions of: The Child Health Questionnaire (CHQ); the assessment questionnaire of the quality of life of the child and parents (Child Quality of Life Parent and Child Forms - TACQOL), etc. (5). The Quality of Life Questionnaire, Short Form (SF-12) was developed by the Medical Outcomes Study. The abbreviated form survey instrument provides a solution to the problem faced by many medical investigators of having to restrict the length of the survey. The instrument was designed to reduce respondent burden while achieving minimum standards of accuracy for the purpose of group comparisons involving multiple dimensions of health (6).

The study aim was to assess the QoL of patients admitted in an Emergency Department (ED), with various polytrauma, from Galati county, by applying a validated questionnaire.

MATERIALS AND METHODS

The study group consisted of 101 subjects, aged between 15 years and 17 years and 11 months, admitted in the ED, „Sf. Ioan" Children's Emergency Hospital, Galati.

Questionnaire method. The SF-12 (Short Form-12) questionnaire was applied to assess the health status of pediatric patients aged between 15 and 17 years and 11 months, admitted to the ED with trauma. The informed consent was applied for each patient and for the relative (adult), later he freely consented to answer the questions.

Questionnaire validation. The Cronbach alpha coefficient was calculated = 0.707 and respectively the value based on the standardized items 0.716., so this questionnaire was validated for the Romanian language for our group of patients.

Statistical methods

The data were also processed with the help of statistical software *MS Excel 2010* and *SPSS version 18.0*. The significance threshold used was 95% ($p < 0.05$). The statistical normality of the series of values and checking whether they are contained was checked with Skewness or Kurtosis tests. The mean, median, minimum and maximum values were considered as primary indicators, as well as the standard deviation, the coefficient of variation as dispersion indicators. Nonparametric chi-square tests or the Kruskal Wallis test were used to compare two or more frequencies within the same study group.

RESULTS

Demographic data

Regarding the age group, it varied from 15 to 17.9 years; mean age 16.43 years ±0.88; 69.3% were male subjects (78.3%; 63.6%, respectively 68.9%; p=0.542); 56.4% from urban areas (65.2%; 60.6%, respectively 48.9%; p=0.172). The most frequent diagnosis was represented by sprains (29.7%), especially in 33.3% of 16-year-old children and contusions (21.8%), more frequently in the 17-year-old age group (26.7%). Traumas were identified in 19.8% of patients, more frequently at 16 years (27.3%), and fractures at 13.9% of the total, more frequently at 15 years (17.4%) and 17 years (17.8%) (tab. I).

TABLE I

Distribution of cases according to diagnosis and age groups

Diagnosis	15 years (n=23)		16 years (n=33)		17 years (n=45)		Total (n=101)	
	n	%	n	%	n	%	n	%
Arthralgia	-	-	1	3.0	-	-	1	1.0
Contracture	1	4.3	-	-	-	-	1	1.0
Avulsion	-	-	1	3.0	-	-	1	1.0
Contusion	2	8.7	8	24.2	12	26.7	22	21.8
Sprain	7	30.4	11	33.3	12	26.7	30	29.7
Fracture	4	17.4	2	6.1	8	17.8	14	13.9
Injury	3	13.0	9	27.3	8	17.8	20	19.8
Polytrauma	4	17.4	1	3.0	5	11.1	10	9.9

Analysis of the questionnaire, with the selective presentation of the items

Item 1. General health status. Depending on the diagnosis (p=0.039), the subjects with trauma assessed their general health status as "good" (55%); the subjects with polytrauma rated their general health stats as "good" (70%) (fig. 1).

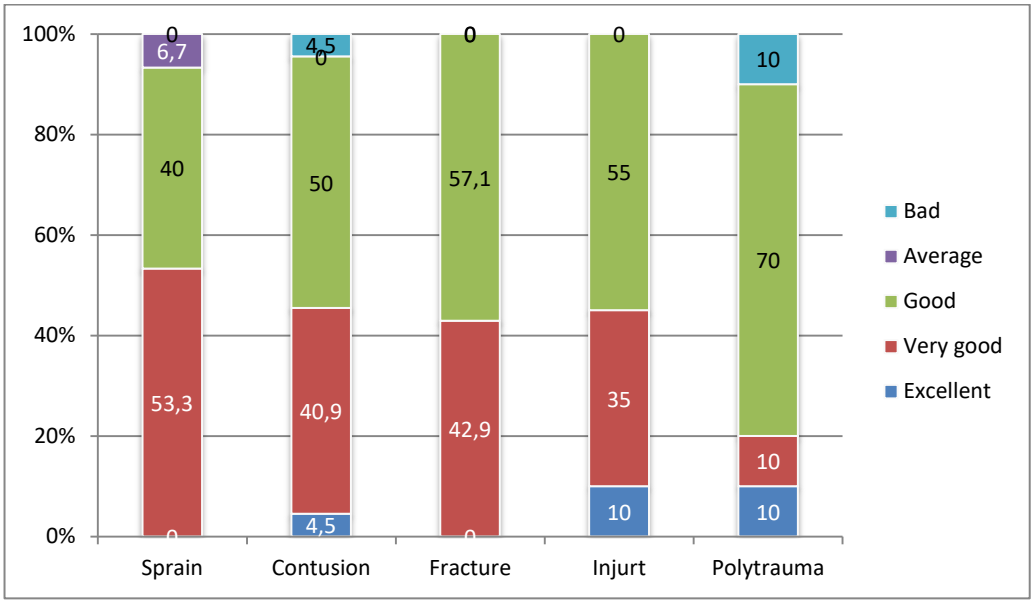

Fig. 1. General health status according to diagnosis

Item 3. Limitation of physical activities depending on the current health status. The activities with the greatest limitation were strenuous activities (52.5%); moderate activities (49.5%) (p=0.001).

Item 10. Affecting social activities by the state of physical or emotional health. 10.9% of subjects believe that physical or emotional health sometimes affected social activity, and 45.5% rarely; most of the

time. Depending on the diagnosis, it was highlighted as follows (p=0.880): in patients with sprains - most of the time (6.7%); most of the time (64.3%) in patients with fractures; most of the time (15%) in trauma patients (fig. 2).

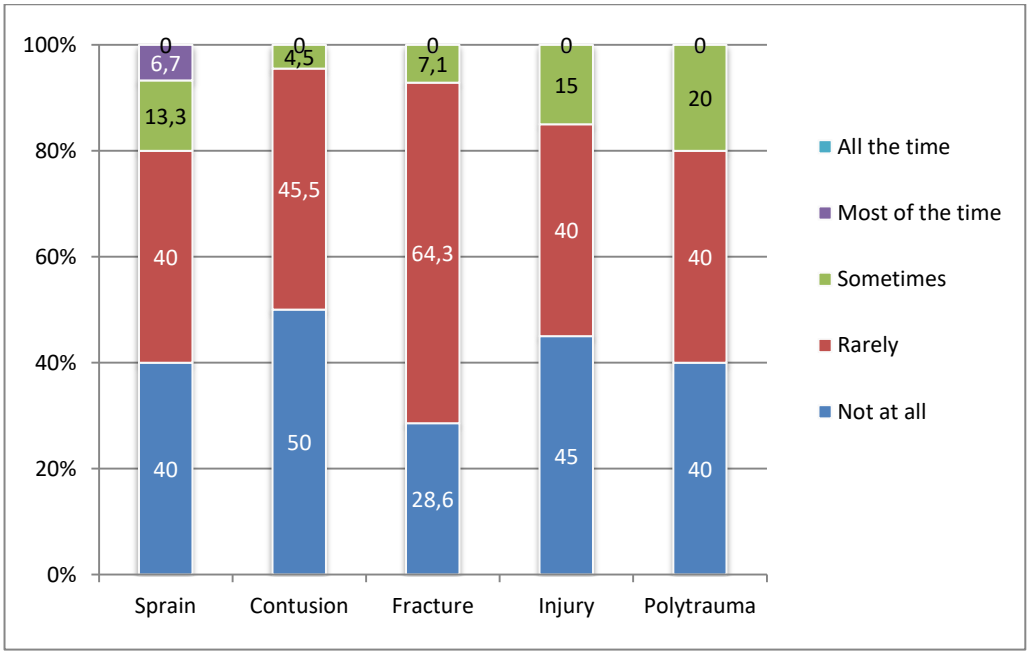

Fig. 2. The influence of social activities by the state of physical health or emotional depending on the diagnosis

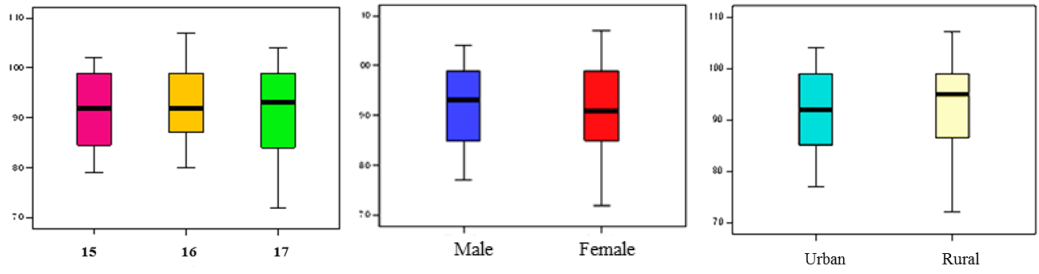
Evaluation of scores for the applied questionnaire

The mean SF-12 score was slightly higher in the 16-year-old age group (91.61; 92.61; respectively 91.64; p=0.839). The mean SF-12 score was slightly lower in females (92.33 and 91.10 respectively; p=0.460). The mean SF-12 score was slightly lower in urban patients (91.23 vs. 92.89; p=0.284) (fig. 3).



a. **b.** **c.**

Fig. 3. The average level of the SF-12 score compared by age groups (a.) and compared by gender (b.) and residence areas (c.)

The mean SF-12 score was significantly lower in patients with sprain (score=89.20) or polytrauma (score=89.90) and significantly higher in patients with contusions (score=96) (p=0.018) (tab. II).

The multivariate analysis revealed that the limitation of physical activities due to the health status (R square =0.046; p=0.339), accompanied or not by emotional limitations (R square =0.060; p=0.699) did not significantly affect the QoL (tab. III).

TABLE II.

Descriptive indicators of SF-12 score by health status

Gender	N	Mean	Std. deviation	Std. error	Confidence interval 95%		Min	Max	F test (ANOVA) p
					-95%CI	+95%CI

DISCUSSION

QoL measurement is currently an important outcome indicator in evaluating interventions and medical treatments (7), in understanding the burden of disease, in identifying health inequalities, in allocating health resources and in epidemiological studies (8) and health surveys (9). In clinical practice, it has been suggested that QoL tools can be useful in identifying and prioritizing health problems for patients (10), facilitating communication between patients and medical staff, identifying hidden or unexpected health problems (11), as decision aids and in monitoring changes in patients' health or detecting responses to treatment (12).

In our study, the SF-12 health-related quality of life score was slightly lower in patients whose physical and emotional health greatly affected social activities. The degree of impairment in the patient who felt a lot of change in physical and/or emotional health reduced the SF-12 score by 20% (p=0.829). Very intense body pain in the past four weeks was associated with a 24% lower SF-12 global score, but the difference was not statistically significant (p=0.308). The difference between the mean levels of SF-12 global score was not statistically significant according to the impairment of usual work by the pain felt in the last four weeks. The degree of impairment in patients who experienced a lot of pain decreased the SF-12 score by 14% (p=0.706). Physical and emotional health status that affected social activities was not significantly associated with SF-12 global score. The degree of impairment in patients who felt most of the time the change in social status decreased the SF-12 score by 17% (p=0.898).

The mean level of SF-12 scores differed significantly depending on the general health status (p=0.001): on the total study group, a reduced impairment of the QoL was revealed, the mean score was 91.95±7.67, representing 85.9% of the maximum value recorded; the lowest mean value was recorded in patients with a poor general condition (86.67±11.93), without significant differences compared to the mean level recorded for the other responses (p=0.884); the highest mean value was recorded in patients with an excellent general condition (95.20±8.18) without significant differences compared to the average level recorded for the other responses (p=0.999).

As compared to the previous year, the mean level of SF-12 scores registered significant differences according to the current health status (p=0.019): the lowest mean value was registered in patients with a much worse current state (88.50 ±8.36), significant difference compared to the average level recorded for the other responses (p=0.038); the highest average value was recorded in patients with a general condition currently approximately the same as the previous year (93.86±7.33) (p=0.038).

As shown by other recently published studies, the decrease in the health-related quality of life of children after trauma contributes to the increase in caregiver stress and family burden. Posttraumatic stress correlates with changes in QoL and with significant impact on the child's physical, social and family activities. The development of QoL instruments for children and adolescents has continued in recent years, especially with regard to specific questionnaires (13).
